Human Health Effects:

Evidence for Carcinogenicity:

CLASSIFICATION: D; not classifiable as to human carcinogenicity. BASIS FOR CLASSIFICATION: Based on no human carcinogenicity data and inadequate animal data. HUMAN CARCINOGENICITY DATA: None. ANIMAL CARCINOGENICITY DATA: Inadequate.
[U.S. Environmental Protection Agency's Integrated Risk Information System (IRIS) on methyl ethyl ketone (78-93-3) Available from: http://www.epa.gov/ngispgm3/iris on the Substance File List as of March 15, 2000]**PEER REVIEWED**

Human Toxicity Excerpts:

HIGH ATM CONCN OF **METHYL ETHYL KETONE** IS IRRITATING TO THE EYES, NOSE, AND THROAT AND PROLONGED EXPOSURE MAY PRODUCE CNS DEPRESSION ... NO UNTOWARD EFFECTS HAVE BEEN REPORTED FOR CHRONIC EXPOSURE TO LOW CONCN. PROLONGED SKIN CONTACT MAY DEFAT THE SKIN AND PRODUCE DERMATITIS. IF SPLASHED IN THE EYES IT MAY PRODUCE PAINFUL IRRITATION AND CORNEAL INJURY.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

... WORKERS EXPOSED TO 300-500 PPM COMPLAINED OF HEADACHE, IRRITATION, AND NAUSEA. EXPOSURES TO 700 PPM LED TO NO PERMANENT UNTOWARD EFFECTS. MOMENTARY EXPOSURE TO 33,000 AND 100,000 PPM PRODUCED INTOLERABLE IRRITATION OF THE EYES, NOSE, AND THROAT.
[Clayton, G. D. and F. E. Clayton (eds.). Patty's Industrial Hygiene and Toxicology: Volume 2A, 2B, 2C: Toxicology. 3rd ed. New York: John Wiley Sons, 1981-1982. 4730]**PEER REVIEWED**

SHORT EXPOSURE OF WORKERS TO 500 PPM ... IN AIR PROVOKED NAUSEA AND VOMITING ... SEVERAL CASES OF PERIPHERAL NEUROPATHY ... OBSERVED /AFTER/ ACUTE PROLONGED OR REPEATED EXPOSURE. NEUROPATHY IS USUALLY SYMMETRICAL, PAINLESS WITH SENSORY LESIONS PREDOMINATING; IT MAY INVOLVE UPPER OR LOWER LIMBS; IN SOME CASES THE FINGERS HAVE BEEN AFFECTED FOLLOWING IMMERSION ... IN THE LIQUID. DERMATITIS ... REPORTED AFTER IMMERSION IN THE LIQUID AND AFTER EXPOSURE TO CONCN VAPORS. /KETONES/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1171]**PEER REVIEWED**

METHYL ETHYL KETONE IS IMPLICATED AS THE CAUSE OF RETROBULBAR NEURITIS IN PT WHO USED THE SOLVENT IN REMOVING PAINT FROM AN AIRPLANE HANGAR.

[BERG EF; ANN OPHTHALMOL 3 (12): 1351 (1971)]**PEER REVIEWED**

Exposure of the forearm for 1 hr/day for 6 consecutive days produced damage to the horny layer of the epithelium. ... **Methyl ethyl ketone** can defat and partially dehydrate the stratum corneum of human skin without producing irritation or inflammation.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A workman splashed his eye accidentally /with **methyl ethyl ketone/,** but the next day had only slight conjunctival hyperemia and no residual corneal injury. Despite the mildness of the injury, in the next few days the affected eye developed severe anterior uveitis triggered by slight trauma.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Toxic effects of common organic solvents on workers /were/ examined. The most notable acute effects of occupational exposure to organic solvents are /CNS depression/ and other nerve dysfunctions. The common symptoms of short term exposure are fatigue, headache, nausea, sleep disturbance, and alteration in memory. Psychomotor performance of adverse effects on intellectual or memory functions are demonstrated with psychological test batteries after long-term occupational exposure to organic solvents. The mutagenic, carcinogenic, and toxicological effects of ... **methyl ethyl ketone ...** are summarized. ... In clinical observations, the effects of organic solvents can cause increased excretion of abnormal cells and protein in urine. This indicates the possible correlation between long-term exposure and renal disease.
[Bang KM; Health Hazards in the Occupational Environment 7 (3): 15-29 (1984)]**PEER REVIEWED**

A case of contact urticaria (CU) caused by **methyl ethyl ketone (**MEK) was reported. ... A cotton swab test with MEK to the normal skin on his forearm caused the skin to turn bright red. The spot was itchy, but no induration or edema was noticed. The reaction reached its maximum after 15 minutes and then gradually faded. The test was repeated after two days with the same results. Application of the same grade MEK to five medical staff members produced no reaction. ... MEK should be added to the list of agents that are not only irritants, but can also cause contact urticaria.
[Varigos GA, Nurse DS; Contact Dermatitis 15 (4): 259-60 (1986)]**PEER REVIEWED**

... Has a low toxicity following both acute and chronic exposures.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

HIGH ATM CONCN ... ARE IRRITATING TO THE EYES, NOSE, AND THROAT AND PROLONGED EXPOSURE MAY PRODUCE CNS DEPRESSION ... NO UNTOWARD EFFECTS HAVE BEEN REPORTED FOR CHRONIC EXPOSURE TO LOW CONCN. PROLONGED SKIN CONTACT MAY DEFAT THE SKIN AND PRODUCE DERMATITIS. IF SPLASHED IN THE EYES IT MAY PRODUCE PAINFUL IRRITATION AND CORNEAL INJURY.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New

York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

To determine whether unchanged solvent urinary concentration could be used as a biological exposure index, workers occupationally exposed to various solvents were studied. Nine unrelated groups (a total of 659 males) working in plastic boat, chemical, plastic button, paint, and shoe factories were studied. Urine samples were collected at the beginning of the workshift and at the end of the first half of the shift. A close relationship (correlation coefficient always above 0.85) between the average environmental solvent concentration (mg/cu m) measured in the breathing zone and the urinary concentration of unchanged solvent (ug/l) was observed.
[Ghittori S et al; Am Ind Hyg Assoc J 48 (9): 786-90 (1987)]**PEER REVIEWED**

... Seventy healthy male and female volunteers, 18 to 32 years old, with no previous prolonged exposure to solvents were exposed to 0 or 250 ppm acetone, 200 ppm MEK, or 125 ppm acetone plus 100 ppm MEK vapors for 4 hours in an exposure chamber. Expired air samples were collected before exposure, after 2 and 4 hours exposure, 90 minutes after exposure ended, and the next morning. Blood samples were collected on the day preceding exposure, at 2 or 4 hours of exposure, 2 hours after exposure ended, and the following day. Samples were analyzed for acetone and MEK by gas or gas/liquid chromatography. ... Blood MEK or acetone concentrations continued to increase throughout exposure, the increases between 2 and 4 hours being larger in the case of acetone. Acetone concentrations in the breath took longer to decrease than those of MEK. No interactive effects were noted in the combined exposures. Blood acetone and MEK concentrations were moderately correlated with their breath concentrations. Blood MEK and acetone concentrations tended to be lower in female subjects than in males; however, the differences were significant only for acetone in the combination exposure after 2 hours exposure and 90 minutes postexposure. ...
[Brown WD et al; The Changing Nature of Work and Workforce, Proceedings of the Third Joint US-Finish Science Symposium p.111-14 (1986)]**PEER REVIEWED**

A 47-yr old woman inadvertently ingested an unknown amt of MEK and was found unconscious, hyperventilating, and suffering from severe metabolic acidosis. Her plasma concn of MEK was 950 mg/L. She responded promptly to an infusion of sodium hydrogen carbonate and was discharged from the hospital after a wk. The metabolic effects of MEK ingestion by humans are not well characterized and it is uncertain that the acidosis was produced by MEK.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

... exposure to 266-797 mg/cu m (90-270 ppm) for up to 4 hr/day caused his subjects to underestimate times of 5 to 30 sec ... on the other hand, found that a 4-hr exposure of human subjects to 590 mg/cu m (200 ppm) had no significant effect in a variety of behavioral test. These included psychomotor, visual vigilance, dual task, sensorimotor and psychological tests. Solvent mixtures of 295 mg MEK/cu m (100 ppm) and 298 mg acetone/cu m (125 ppm) similarly had no significant effect on the results of these behavioral tests.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

MEK (0.1 mL) rubbed into volar forearm skin daily for 18 days and left uncovered did not produce

persistent erythema or swelling ... A 5-min contact with 1.5 mL of analytical grade MEK confined to a 20-mm circle on the forearm produced a temporary whitening of the skin, but no visible erythema, alteration in cutaneous blood flow or other indication of irritation to the skin ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

Long-term exposure of 51 Italian workers to MEK produced indications of neurotoxicity with slightly, but not significantly, reduced nerve conduction velocities and various other symptoms such as headache, loss of appetite and weight, GI upset, dizziness, dermatitis and muscular hypotrophy, but no clinically recognizable neuropathy. ... There has been a brief report of chronic exposure of American workers, in a factory producing coated fabric, to 885-1770 mg MEK/cu m (300-600 ppm) in the apparent absence of other solvents. ... Workers complained of dermatoses and numbness of fingers and arms.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.82 (1993)]**PEER REVIEWED**

In a historical prospective morality study of 446 male workers in two MEK dewaxing plants, with an average follow up of 13.9 years, the observed deaths (46) were below the expected (55.51). There was a slight deficiency of deaths from neoplasms (13 observed; 14.26 expected) but there was a significant incr of deaths from tumors of the buccal cavity and pharynx (2 observed; 0.13 expected). However, there were significantly fewer deaths from lung cancer (1 observed; 6.02 expected). In view of the small numbers, it was concluded that there was no clear evidence of cancer hazard in these workers ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.89 (1993)]**PEER REVIEWED**

The application of MEK to the forearm skin of two volunteers for 1 hr/day on six successive days damaged only the stratum corneum and that the dermal toxicity was similar to ethanol. Opdyke indicated that the application of 20 percent MEK in petrolatum to human forearm skin for 48 hr did not cause any irritation and that no sensitization reactions occurred when the same concentration was tested on 24 volunteers.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

Two cases of acute poisoning in a raincoat manufacturing operation where the seams were waterproofed with a resin dissolved in either acetone or MEK were reported. Samples of the workroom air indicated that the MEK concentration ranged from 398 to 561 ppm, whereas the acetone concentration ranged from 330 to 495 ppm. Two female employees were reportedly affected by the solvent vapors on different occasions. The first complained of stomach distress and watery eyes one morning, and later was found unconscious in a rest room. The employee had a strong acetone odor on her breath, but no acetonuria upon admission to the local hospital. She was treated with a CNS stimulant and awoke immediately, but complained of a severe headache. The patient was discharged from the hospital on the day following admission. The second case followed the first one by 1 day and was apparently less severe. The individual fainted and convulsed at the work site but regained consciousness immediately afterwards. At the hospital she was confused and had a headache, but after 1 hr of observation she was allowed to return home.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New

York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case study where a male patient attempted suicide by ingesting approximately 100 ml of an adhesive cement that contained 39 percent cyclohexanone, 28% MEK, 18% acetone was presented. The individual reportedly drank about 720 ml of sake (10 percent ethanol) 30 min prior to drinking the adhesive solution. The patient was unconscious when taken to a hospital about 2 hr after the ingestion of the solvent mixture. Gastric lavage, plasma exchange, and charcoal hemoperfusion were all performed, and the patient regained consciousness about 7 hr after ingestion; however, signs of systemic toxicity persisted. High blood concentrations of a cyclohexanone metabolite (cyclohexanal) were thought to be responsible for the coma, whereas the hyperglycemia was attributed to acetone.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of retrobulbar neuritis in a sailor who was using large quantities of MEK as a paint remover was reported. The affected individual complained of blurred vision, light-headedness, and nausea after being exposed to MEK vapor for 1.5 hr. Upon admission to a military hospital, the patient's near- and far-field visual acuity was reduced and blind spots were markedly enlarged when a white target was viewed. An ophthalmoscopic examination, however, did not reveal any abnormalities. Clinical testing on the day of admission revealed elevations in blood methanol and formaldehyde. Visual acuity returned to normal within 2 days of admission; however, the blood methanol levels did not return to normal until the sixth day of hospitalization. /It was/ concluded that MEK was the causative agent for the optic nerve damage that was observed. The MEK was assumed to have been systemically absorbed both dermally and through the lungs and then partially metabolized to methanol, which subsequently affected the optic nerve and cerebral cortex.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of toxic encephalopathy with dementia and cerebellar ataxia in a 38-year-old male who spray-painted a truck in an unventilated garage with a paint that contained toluene, MEK, and propylene glycol. As time passed following the exposure, the individual began to experience memory problems along with headaches, shortness of breath, appetite and sleep disturbances, ataxia, and suicidal depression. Neuropsychological evaluations over a 2.5 year period revealed distinct cognitive, motor, and behavioral changes.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1769]**PEER REVIEWED**

The pharmacokinetics of MEK in 70 male and female volunteers following a 4-hr inhalation exposure either alone (200 ppm) or in combination with acetone (225 ppm, 1:1.25 ratio) was described. Blood and expired air elimination data for the MEK-exposed individuals revealed on average that (1) MEK steady-state breath levels of about 10 to 12 ppm were attained, (2) non-steady-state peak blood levels of 3 to 4 ug/ml occurred, (3) no significant difference in uptake or elimination was observed for males and females, and (4) no appreciable interaction affecting elimination took place with the combined exposures.

Artificial leather workers /are at risk of exposure/.
[Arena, J.M. and Drew, R.H. (eds.) Poisoning-Toxicology, Symptoms, Treatments. 5th ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 358]**PEER REVIEWED**

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,221,857 workers (201,308 of these are female) are potentially exposed to **methyl ethyl ketone** in the US(1). Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used(SRC). The 8 hour TWA exposure to **methyl ethyl ketone** was 45.4 ppm in a survey of 50 occupationally exposed male subjects working in a magnetic videotape producing factory(2). These workers had average concns of **methyl ethyl ketone** of 2 ppm and 1.4 mg/l in breath and blood samples respectively(2). The mean concn of **methyl ethyl ketone** in the breathing zones of 47 US plants using polyurethane coatings was 4.33 ppm(3). **Methyl ethyl ketone** was detected in the breathing zones in 20 of 70 samples (mean concn 12 mg/cu m) obtained from autobody shops and spray paint shops in Australia(4).

Body Burden:

Detected in 5 of 8 samples of mother's milk from 4 USA urban areas.
[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982)]**PEER REVIEWED**

The kinetics of inhaled **methyl ethyl ketone (**MEK) in human volunteers was studied in an exposure chamber. Relative pulmonary uptake was about 53% throughout a 4 hr exposure period at 200 ppm. Blood MEK concentration rose steadily until the end of exposure. Repeated bicycle exercise increased the overall blood MEK level markedly in comparison to sedentary activity, with transient peaks in association with cycling; thus blood MEK concentration depended both on the rate of uptake and the amount taken up. Only 3% of the absorbed dose was excreted unchanged by exhalation. A well known metabolite of MEK, 2,3-butanediol, was detected in the urine with maximum rates of excretion at about 6 to 12 hr from the beginning of exposure. About 2% of the MEK dose taken up by the lungs was excreted in the urine as 2,3-butanediol. ... Elimination of MEK in blood appeared to exhibit two phases: the initial alpha-phase (T1/2= 30 min; kel alpha= 0.023) over the first post-exposure hour, followed by the terminal beta-phase (T1/2= 81 min; kel beta= 0.009).
[Liira J et al; Int Arch Occup Environ Health 60 (3): 195-200 (1988)]**PEER REVIEWED**

Worker exposures were investigated in April 1983 at the Hoover Company, North Canton, Ohio. ... Area and personal air samples for numerous contaminants were collected and nonionizing radiation levels were measured. ... General medical questionnaires and blood tests for **methyl ethyl ketone (**MEK) were given to exposed workers. ... No respiratory symptoms or pulmonary function disorders were identified in the foundry workers, and MEK was detected in the blood of only one worker at 1.4 ug/ml. ...

Suicidal ingestion of the peroxide of **methyl ethyl ketone** caused a severe metabolic acidosis, hemolysis, esophageal and gastric necrosis, gastric perforation, and death.
[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 1000]**PEER REVIEWED**

All 4 peroxides are irritants of the skin and mucous membranes; however, the effects of **methyl ethyl ketone** (MEK, or 2-**butanone**) and cyclohexanone peroxides are much greater than those of benzoyl and dicumyl peroxides. The relevance of studies on hemolytic effects of the peroxides to occupational exposure of man is uncertain, and there are no other conclusive reports of systemic toxic effects.
[Aringer L; Arbetarskyddsstyrelsen, Publikationsservice, 171 84 Solna, Sweden, 64 pp. (1985)]**PEER REVIEWED**

Fatal massive peripheral zonal hepatic necrosis developed in a 47 yr old man who accidentally ingested a solution of **methyl ethyl ketone** peroxide in dimethyl phthalate. Such solutions contain about 10% active oxygen. The clinical course was characterized by temporary cardiac arrest, abdominal burns, severe metabolic acidosis, rapid hepatic failure, rhabdomyolysis and respiratory insufficiency. A fatal outcome resulted 4 days afterwards from hepatic coma associated with blood coagulation disorders. Microscopical examination revealed massive periportal hepatic necrosis accompanied by atypical pseudoductular proliferation. The proliferating cells were probably of bile duct origin and exhibited atypia and mitoses.
[Karhunen PJ et al; Hum Exp Toxicol 9 (3): 197-200 (1990)]**PEER REVIEWED**

This compound ... has a workplace exposure limit of 0.2 ppm (1.5 mg/cu m), which is a ceiling limit and should not be exceeded at any time during the work shift. It is a respiratory tract irritant and a severe eye and skin irritant. The maximum nonirritating strength for skin was 1.5%, for eyes 0.6%. Skin irritation was delayed, with erythema and edema appearing within 2 to 3 days. Eyes washed within 4 sec after exposure resulted in no adverse effects. However, it has been noted that single MEK peroxide exposures to the eye can exacerbate preexisting corneal and limbal disease.

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 16,366 workers are potentially exposed to 2-**butanone** peroxide in the US(1). Analysis of 35 air samples collected in the working environments of 5 Swedish plants manufacturing reinforced plastics detected 2-**butanone** peroxide in 13 samples above the detection limit (0.1 mg/cu m) with a maximum concn of 72 mg/cu m(2). Occupational exposure to 2-**butanone** peroxide may occur through inhalation and dermal contact with this compound at workplaces where 2-**butanone** peroxide is produced or used(SRC). Consumer exposure may occur during the use of fiber glass resin kits for boat and automobile repair(4).

METHYL ETHYL KETONE IS IMPLICATED AS THE CAUSE OF RETROBULBAR NEURITIS IN PT WHO USED THE SOLVENT IN REMOVING PAINT FROM AN AIRPLANE HANGAR.

[BERG EF; ANN OPHTHALMOL 3 (12): 1351 (1971)]**PEER REVIEWED**

Exposure of the forearm for 1 hr/day for 6 consecutive days produced damage to the horny layer of the epithelium. ... **Methyl ethyl ketone** can defat and partially dehydrate the stratum corneum of human skin without producing irritation or inflammation.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A workman splashed his eye accidentally /with **methyl ethyl ketone/,** but the next day had only slight conjunctival hyperemia and no residual corneal injury. Despite the mildness of the injury, in the next few days the affected eye developed severe anterior uveitis triggered by slight trauma.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Toxic effects of common organic solvents on workers /were/ examined. The most notable acute effects of occupational exposure to organic solvents are /CNS depression/ and other nerve dysfunctions. The common symptoms of short term exposure are fatigue, headache, nausea, sleep disturbance, and alteration in memory. Psychomotor performance of adverse effects on intellectual or memory functions are demonstrated with psychological test batteries after long-term occupational exposure to organic solvents. The mutagenic, carcinogenic, and toxicological effects of ... **methyl ethyl ketone ...** are summarized. ... In clinical observations, the effects of organic solvents can cause increased excretion of abnormal cells and protein in urine. This indicates the possible correlation between long-term exposure and renal disease.
[Bang KM; Health Hazards in the Occupational Environment 7 (3): 15-29 (1984)]**PEER REVIEWED**

A case of contact urticaria (CU) caused by **methyl ethyl ketone (**MEK) was reported. ... A cotton swab test with MEK to the normal skin on his forearm caused the skin to turn bright red. The spot was itchy, but no induration or edema was noticed. The reaction reached its maximum after 15 minutes and then gradually faded. The test was repeated after two days with the same results. Application of the same grade MEK to five medical staff members produced no reaction. ... MEK should be added to the list of agents that are not only irritants, but can also cause contact urticaria.
[Varigos GA, Nurse DS; Contact Dermatitis 15 (4): 259-60 (1986)]**PEER REVIEWED**

... Has a low toxicity following both acute and chronic exposures.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

To determine whether unchanged solvent urinary concentration could be used as a biological exposure index, workers occupationally exposed to various solvents were studied. Nine unrelated groups (a total of 659 males) working in plastic boat, chemical, plastic button, paint, and shoe factories were studied. Urine samples were collected at the beginning of the workshift and at the end of the first half of the shift. A close relationship (correlation coefficient always above 0.85) between the average environmental solvent concentration (mg/cu m) measured in the breathing zone and the urinary concentration of unchanged solvent (ug/l) was observed.
[Ghittori S et al; Am Ind Hyg Assoc J 48 (9): 786-90 (1987)]**PEER REVIEWED**

... Seventy healthy male and female volunteers, 18 to 32 years old, with no previous prolonged exposure to solvents were exposed to 0 or 250 ppm acetone, 200 ppm MEK, or 125 ppm acetone plus 100 ppm MEK vapors for 4 hours in an exposure chamber. Expired air samples were collected before exposure, after 2 and 4 hours exposure, 90 minutes after exposure ended, and the next morning. Blood samples were collected on the day preceding exposure, at 2 or 4 hours of exposure, 2 hours after exposure ended, and the following day. Samples were analyzed for acetone and MEK by gas or gas/liquid chromatography. ... Blood MEK or acetone concentrations continued to increase throughout exposure, the increases between 2 and 4 hours being larger in the case of acetone. Acetone concentrations in the breath took longer to decrease than those of MEK. No interactive effects were noted in the combined exposures. Blood acetone and MEK concentrations were moderately correlated with their breath concentrations. Blood MEK and acetone concentrations tended to be lower in female subjects than in males; however, the differences were significant only for acetone in the combination exposure after 2 hours exposure and 90 minutes postexposure. ...
[Brown WD et al; The Changing Nature of Work and Workforce, Proceedings of the Third Joint US-Finish Science Symposium p.111-14 (1986)]**PEER REVIEWED**

A 47-yr old woman inadvertently ingested an unknown amt of MEK and was found unconscious, hyperventilating, and suffering from severe metabolic acidosis. Her plasma concn of MEK was 950 mg/L. She responded promptly to an infusion of sodium hydrogen carbonate and was discharged from the hospital after a wk. The metabolic effects of MEK ingestion by humans are not well characterized and it is uncertain that the acidosis was produced by MEK.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

... exposure to 266-797 mg/cu m (90-270 ppm) for up to 4 hr/day caused his subjects to underestimate times of 5 to 30 sec ... on the other hand, found that a 4-hr exposure of human subjects to 590 mg/cu m (200 ppm) had no significant effect in a variety of behavioral test. These included psychomotor, visual vigilance, dual task, sensorimotor and psychological tests. Solvent mixtures of 295 mg MEK/cu m (100 ppm) and 298 mg acetone/cu m (125 ppm) similarly had no significant effect on the results of these behavioral tests.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

MEK (0.1 mL) rubbed into volar forearm skin daily for 18 days and left uncovered did not produce

persistent erythema or swelling ... A 5-min contact with 1.5 mL of analytical grade MEK confined to a 20-mm circle on the forearm produced a temporary whitening of the skin, but no visible erythema, alteration in cutaneous blood flow or other indication of irritation to the skin ... .

Long-term exposure of 51 Italian workers to MEK produced indications of neurotoxicity with slightly, but not significantly, reduced nerve conduction velocities and various other symptoms such as headache, loss of appetite and weight, GI upset, dizziness, dermatitis and muscular hypotrophy, but no clinically recognizable neuropathy. ... There has been a brief report of chronic exposure of American workers, in a factory producing coated fabric, to 885-1770 mg MEK/cu m (300-600 ppm) in the apparent absence of other solvents. ... Workers complained of dermatoses and numbness of fingers and arms.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.82 (1993)]**PEER REVIEWED**

In a historical prospective morality study of 446 male workers in two MEK dewaxing plants, with an average follow up of 13.9 years, the observed deaths (46) were below the expected (55.51). There was a slight deficiency of deaths from neoplasms (13 observed; 14.26 expected) but there was a significant incr of deaths from tumors of the buccal cavity and pharynx (2 observed; 0.13 expected). However, there were significantly fewer deaths from lung cancer (1 observed; 6.02 expected). In view of the small numbers, it was concluded that there was no clear evidence of cancer hazard in these workers ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.89 (1993)]**PEER REVIEWED**

The application of MEK to the forearm skin of two volunteers for 1 hr/day on six successive days damaged only the stratum corneum and that the dermal toxicity was similar to ethanol. Opdyke indicated that the application of 20 percent MEK in petrolatum to human forearm skin for 48 hr did not cause any irritation and that no sensitization reactions occurred when the same concentration was tested on 24 volunteers.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

Two cases of acute poisoning in a raincoat manufacturing operation where the seams were waterproofed with a resin dissolved in either acetone or MEK were reported. Samples of the workroom air indicated that the MEK concentration ranged from 398 to 561 ppm, whereas the acetone concentration ranged from 330 to 495 ppm. Two female employees were reportedly affected by the solvent vapors on different occasions. The first complained of stomach distress and watery eyes one morning, and later was found unconscious in a rest room. The employee had a strong acetone odor on her breath, but no acetonuria upon admission to the local hospital. She was treated with a CNS stimulant and awoke immediately, but complained of a severe headache. The patient was discharged from the hospital on the day following admission. The second case followed the first one by 1 day and was apparently less severe. The individual fainted and convulsed at the work site but regained consciousness immediately afterwards. At the hospital she was confused and had a headache, but after 1 hr of observation she was allowed to return home.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New

York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case study where a male patient attempted suicide by ingesting approximately 100 ml of an adhesive cement that contained 39 percent cyclohexanone, 28% MEK, 18% acetone was presented. The individual reportedly drank about 720 ml of sake (10 percent ethanol) 30 min prior to drinking the adhesive solution. The patient was unconscious when taken to a hospital about 2 hr after the ingestion of the solvent mixture. Gastric lavage, plasma exchange, and charcoal hemoperfusion were all performed, and the patient regained consciousness about 7 hr after ingestion; however, signs of systemic toxicity persisted. High blood concentrations of a cyclohexanone metabolite (cyclohexanal) were thought to be responsible for the coma, whereas the hyperglycemia was attributed to acetone.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of retrobulbar neuritis in a sailor who was using large quantities of MEK as a paint remover was reported. The affected individual complained of blurred vision, light-headedness, and nausea after being exposed to MEK vapor for 1.5 hr. Upon admission to a military hospital, the patient's near- and far-field visual acuity was reduced and blind spots were markedly enlarged when a white target was viewed. An ophthalmoscopic examination, however, did not reveal any abnormalities. Clinical testing on the day of admission revealed elevations in blood methanol and formaldehyde. Visual acuity returned to normal within 2 days of admission; however, the blood methanol levels did not return to normal until the sixth day of hospitalization. /It was/ concluded that MEK was the causative agent for the optic nerve damage that was observed. The MEK was assumed to have been systemically absorbed both dermally and through the lungs and then partially metabolized to methanol, which subsequently affected the optic nerve and cerebral cortex.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of toxic encephalopathy with dementia and cerebellar ataxia in a 38-year-old male who spray-painted a truck in an unventilated garage with a paint that contained toluene, MEK, and propylene glycol. As time passed following the exposure, the individual began to experience memory problems along with headaches, shortness of breath, appetite and sleep disturbances, ataxia, and suicidal depression. Neuropsychological evaluations over a 2.5 year period revealed distinct cognitive, motor, and behavioral changes.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1769]**PEER REVIEWED**

The pharmacokinetics of MEK in 70 male and female volunteers following a 4-hr inhalation exposure either alone (200 ppm) or in combination with acetone (225 ppm, 1:1.25 ratio) was described. Blood and expired air elimination data for the MEK-exposed individuals revealed on average that (1) MEK steady-state breath levels of about 10 to 12 ppm were attained, (2) non-steady-state peak blood levels of 3 to 4 ug/ml occurred, (3) no significant difference in uptake or elimination was observed for males and females, and (4) no appreciable interaction affecting elimination took place with the combined exposures.

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,221,857 workers (201,308 of these are female) are potentially exposed to **methyl ethyl ketone** in the US(1). Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used(SRC). The 8 hour TWA exposure to **methyl ethyl ketone** was 45.4 ppm in a survey of 50 occupationally exposed male subjects working in a magnetic videotape producing factory(2). These workers had average concns of **methyl ethyl ketone** of 2 ppm and 1.4 mg/l in breath and blood samples respectively(2). The mean concn of **methyl ethyl ketone** in the breathing zones of 47 US plants using polyurethane coatings was 4.33 ppm(3). **Methyl ethyl ketone** was detected in the breathing zones in 20 of 70 samples (mean concn 12 mg/cu m) obtained from autobody shops and spray paint shops in Australia(4).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983) (2) Sia Gl et al; Environ Monit Assess 19: 401-11 (1991) (3) Myer HE et al; Am Ind Hyg Assoc J 54: 663-70 (1993) (4) Winder C, Turner PJ; Ann Occup Hyg 36: 385-94 (1992)]**PEER REVIEWED**

The general population may be exposed to **methyl ethyl ketone** through the use of commercially available products containing this compound such as paints, adhesives, and rubber cements(SRC). Exposure will also arise from inhalation of ambient air, ingestion of drinking water and food that contains **methyl ethyl ketone(**SRC). The average blood concn of **methyl ethyl ketone** in 600 non-occupationally exposed individuals in the US was 7.1 ppb(1).
[(1) Ashley DL et al; Clin Chem 40: 1401-04 (1994)]**PEER REVIEWED**

Body Burden:

Detected in 5 of 8 samples of mother's milk from 4 USA urban areas.
[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982)]**PEER REVIEWED**

The kinetics of inhaled **methyl ethyl ketone (**MEK) in human volunteers was studied in an exposure chamber. Relative pulmonary uptake was about 53% throughout a 4 hr exposure period at 200 ppm. Blood MEK concentration rose steadily until the end of exposure. Repeated bicycle exercise increased the overall blood MEK level markedly in comparison to sedentary activity, with transient peaks in association with cycling; thus blood MEK concentration depended both on the rate of uptake and the amount taken up. Only 3% of the absorbed dose was excreted unchanged by exhalation. A well known metabolite of MEK, 2,3-butanediol, was detected in the urine with maximum rates of excretion at about 6 to 12 hr from the beginning of exposure. About 2% of the MEK dose taken up by the lungs was excreted in the urine as 2,3-butanediol. ... Elimination of MEK in blood appeared to exhibit two phases: the initial alpha-phase (T1/2= 30 min; kel alpha= 0.023) over the first post-exposure hour, followed by the terminal beta-phase (T1/2= 81 min; kel beta= 0.009).
[Liira J et al; Int Arch Occup Environ Health 60 (3): 195-200 (1988)]**PEER REVIEWED**

Worker exposures were investigated in April 1983 at the Hoover Company, North Canton, Ohio. ... Area and personal air samples for numerous contaminants were collected and nonionizing radiation levels were measured. ... General medical questionnaires and blood tests for **methyl ethyl ketone (**MEK) were given to exposed workers. ... No respiratory symptoms or pulmonary function disorders were identified in the foundry workers, and MEK was detected in the blood of only one worker at 1.4 ug/ml. ...

The following Overview, *** KETONES ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- ACUTE EXPOSURE (ORAL) - Most available information concerns inhalational or dermal exposure. A few cases involving ingestion of **methyl ethyl ketone (**and co-ingestants) or ketone peroxide (with co-ingestants) have resulted in CNS depression, respiratory depression or corrosive effects and sequelae.
- ACUTE INHALATION - The effects vary, depending on extent and duration of exposure. Eye, nose and throat irritation, nausea, headache, vertigo, incoordination, CNS depression, narcosis and cardiorespiratory failure can occur. In most cases, recovery is usually rapid and complete.
- CHRONIC EXPOSURE - The major concern with chronic exposure is axonal neuropathy with secondary myelin damage; usually manifested as paresthesias and muscle weakness. Only six-carbon, linear chain ketones metabolized to gamma-diketones (such as methyl n-butyl ketone) are implicated.
- EYE EXPOSURE - Splash contact causes irritation, which may be slight, moderate, or severe, depending on the ketone. Vapors can cause irritation and lacrimation.
- ROUTES OF EXPOSURE - Ketones are absorbed by ingestion, inhalation, and dermal exposure.
- RELATED COMPOUNDS - Exposure to ketone solvents (**methyl ethyl ketone,** methyl isobutyl ketone, etc) must be distinguished from exposure to the peroxides of these same ketones. KETONE PEROXIDES are highly reactive and corrosive. Management of ketone peroxide exposure is discussed in a separate document.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Splash contact causes irritation, which may be slight, moderate, or severe, depending on the specific ketone; vapors may cause irritation and lacrimation.

CARDIOVASCULAR

0.2.5.1 ACUTE EXPOSURE

- Tachycardia may occur.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Ingestion of significant amounts may cause respiratory depression. Inhalation exposure may produce an anesthetic type of respiratory depression, dyspnea, and

gasping. Pulmonary aspiration may result in chemical pneumonitis.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute inhalation exposure causes a progression of CNS effects, from headache, vertigo, incoordination, narcosis, dizziness, and tremor, to coma. Peripheral neuropathy has been reported following exposure to methyl-n-butyl ketone and 2,5-hexanedione. Trimethylnonanone is not associated with narcosis.
- Chronic exposure causes axonal neuropathy with secondary myelin damage, usually manifested as paresthesias and muscle weakness. Only six-carbon, linear chain ketones metabolized to gamma-diketones (such as methyl n-butyl ketone) are implicated.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Nausea and vomiting may occur.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Ketones may potentiate the hepatotoxicity of halogenated hydrocarbons. They may also inhibit aromatic hydrocarbon metabolism.

ACID-BASE

0.2.11.1 ACUTE EXPOSURE

- Metabolic acidosis has been reported.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Skin exposure to the liquid or vapor may result in dermatitis and paresthesias of affected areas. Contact urticaria has also been reported.

REPRODUCTIVE HAZARDS

- Limited studies have generally documented little or no effect of ketones on reproduction in experimental animals. Human data is lacking. 2,5-Hexanedione has an effect on spermatogenesis in male experimental animals.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- The ketones are generally unclassified by IARC. Those agents evaluated by IARC have been classified as having insufficient evidence to determine human carcinogenicity.

0.2.21.2 HUMAN OVERVIEW

- No adequate human studies exist for the agents in this category.

0.2.21.3 ANIMAL OVERVIEW

- Experimental animal studies are limited, but are generally negative, and agents in this group have little mutagenic activity.

GENOTOXICITY

- Extremely limited data is available for this class of agents. For many specific ketones, no data is available. Some studies report positive findings, but this category of agents appears to be generally non-mutagenic or only weakly mutagenic.

Laboratory:

- Plasma ketone levels are not clinically useful.
- If pulmonary aspiration is suspected, monitor chest x-ray and arterial blood gases or pulse oximetry.

Treatment Overview:

ORAL EXPOSURE

- With ingestion of small amounts the major concern is pulmonary aspiration and gastrointestinal decontamination is not recommended. With ingestion of large amounts there is potential for systemic toxicity from gastrointestinal absorption and GI decontamination is suggested, keeping in mind that pulmonary aspiration is still a concern.
- If the patient is obtunded, seizing, or has significant alterations in mental status, a cuffed endotracheal tube should be inserted prior to gastric aspiration.

1. For moderate ingestions (less than 100 milliliters) activated charcoal alone is recommended.
2. For large ingestions that have occurred within the past hour, careful gastric aspiration followed by activated charcoal is recommended.
   a. The lavage tube should be flexible, well lubricated with a water soluble gel to minimize gagging and vomiting, and of a large enough diameter to minimize vomiting of gastric contents around the tube and potential pulmonary aspiration.
   b. After the tube is in place, evacuate gastric contents rapidly. Repeated instillation of fluid to wash out the stomach is NOT suggested as it probably does not significantly enhance the removal of liquids and may enhance the potential for pulmonary aspiration.
   c. Instill activated charcoal prior to withdrawing the tube.
   d. For ingestions that have occurred more than 2 hours

ago, gastric decontamination is not likely to be of benefit and is generally not warranted.

- Administer activated charcoal for moderate or large ingestions.

1. ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.

- ACIDOSIS - Correct severe acidosis (pH < 7.1) with intravenous sodium bicarbonate. About 1 to 2 milliequivalents/kilogram is a useful starting dose. Monitor arterial blood gases to guide bicarbonate therapy.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
- Treat dermal irritation or burns with standard topical therapy. Patients developing dermal hypersensitivity reactions may require treatment with systemic or topical corticosteroids or antihistamines.

Range of Toxicity:

- The minimal toxic or lethal dose is variable and not well defined. Toxic effects following inhalation exposure depend on air concentration, time of exposure and underlying diseases.
- Exposure to airborne concentrations greater than 300 ppm of **methyl ethyl ketone** may result in discomfort and CNS depression. Methyl-isobutyl ketone produces irritation at an airborne concentration of 100 ppm (Hjelm et al, 1990).

Antidote and Emergency Treatment:

For immediate first aid: Ensure that adequate decontamination has been carried out. If victim is not breathing, start artificial respiration, preferably with a demand-valve resuscitator, bag-valve-mask device, or pocket mask as trained. Perform CPR if necessary. Immediately flush contaminated eyes with gently flowing water. Do not induce vomiting. If vomiting occurs, lean patient forward or place on left side (head-down position, if possible) to maintain an open airway and prevent aspiration. Keep victim quiet and maintain normal body temperature. Obtain medical attention. /Ketones and related compounds/

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissues consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed.

Testing of a drop on rabbit eyes indicates moderate reversible injury, graded 5 on a scale of 1-10. The

compound was tested externally on the eyes of rabbits, and, according to the degree of injury observed after 24 hours, rated on a scale of 1 to 10. The most severely injurious substances have been rated 10.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Male and female Fischer 344 rats were exposed to 0, 1250, 2500, or 5000 ppm **methyl ethyl ketone (**MEK) vapors 6 hr/day, 5 day/wk for 90 days. The 90 day exposures had no adverse effect on the clinical health or growth of male or female rats except for a depression of mean body wt in the 5000 ppm exposure group. The 5000 ppm animals had a slight but significant increase in liver weight, liver weight/body weight ratio, and liver weight/brain weight ratio at necropsy. Serum glutamic-pyruvic transaminase (SGPT) activity in the 2500 ppm female rats was elevated while the 5000 ppm female rats exhibited significantly decreased serum glutamic-pyruvic transaminase SGPT activity. In addition, alkaline phosphatase, potassium, and blood glucose values for the 5000 ppm female rats were increased. ...

Chinese hamsters were exposed to ... **methyl ethyl ketone ...** known to be a strong inducer of aneuploidy in the yeast Saccharomyces cerevisiae. ... Solvent yielded negative results in the micro-nucleus test.
[Basler A; Mutat Res 174 (1): 11-13 (1986)]**PEER REVIEWED**

... Cultures of mature organotypic cord ganglia were extracted from fetal mouse spinal cord with the attached dorsal root. MEK at 300 ug/ml nutrient fluid was added to cultures for periods of up to 7 weeks. Cultures were examined under microscope twice weekly for morphological changes and were sampled at 3, 5, and 7 weeks for electron microscopy. Treated cultures remained viable for the 7 week exposure period. After 6 to 7 weeks of exposure, distinct intraaxonal inclusion occurred along proximal and distal internodes of occasional sensory peripheral nerves (PNS). The structures lengthened and darkened throughout the exposure period and were often associated with axoplasmic granularity. The earliest change in cytoplasm was dispersion of Nissl bodies, which resulted in excessive numbers of free ribosomes or polyribosomal changes. There was a distension of neuronal cisternal systems. By week 5 there were abnormal amounts of smooth or agranular endoplasmic reticulum which appeared swollen with a translucent material. A swollen agranular recticulum was often associated with foci of axoplasmic debris. By week 7, intra-axonal cores of debris and myelin whorls were documented in 25% of the central nervous system and sensory perpipheral nerves axons examined ultrastucturally. ...

The developmental effects observed at an MEK vapor concentration of 3000 ppm were reexamined. Pregnant Sprague-Dawley rats were exposed to 400, 1000, or 3000 ppm of MEK for 7 hr/day on days 6 to 15 of gestation. There were no effects on maternal liver weight; however, a significant decrease in maternal body weight gain was observed in the animals exposed to 3000 ppm of MEK. In addition, none of the exposures affected the pregnancy rate, the number of implantations or fetal resorptions, the litter size, or the fetal body weight. Unlike the initial study, there were no gross or soft-tissue malformations at any exposure level; however, the 3000-ppm exposure caused a significant increase in the incidence of delayed skeletal ossifications (skull and neck) and an increase in the incidence of extra lumbar ribs. /It

was/ concluded that MEK was not embryotoxic or teratogenic and only slightly fetotoxic in the rat at exposure concentrations of 3000 ppm.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1759]**PEER REVIEWED**

Groups of pregnant and nonpregnant mice were exposed to MEK vapor concentrations of 400, 1000, or 3000 ppm for 7 hr/day for 10 consecutive days (for pregnant mice, days 6 to 15 of gestation). The nonpregnant and pregnant mice showed no differences in sensitivity to the MEK exposures. The maternal body weight gain, extragestational weight gain, uterine weight, pregnancy rate, and implantation ratio were not affected by exposure to MEK vapors relative to control. The 3000-ppm exposure did, however, result in a relative increase in maternal liver and kidney weight. The percentage of live fetuses, resorptions, and dead fetuses per litter was also unaffected by the treatment. A concentration-related decrease in fetal weight was observed for both the male and females. Although there were no statistically significant increases in the number of malformed fetuses per litter, there were several atypical malformations (cleft palate, fused ribs, missing vertebrae, and syndactyly) not often found in control litters. A statistically significant increase in the incidence of misaligned sternebrae was observed in the fetuses exposed to 3000 ppm of MEK. No developmental or maternal effects were observed at vapor concentrations of 1000 ppm or less. After considering the results from the present study together with results obtained in rats, the authors concluded that MEK vapors caused mild developmental toxicity at concentrations that caused maternal toxicity.

TSCA Test Submissions:

The ability of **methyl ethyl ketone** to induce morphological transformation in the BALB/3T3 mouse cell line (Cell Transformation Assay) was evaluated both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary clonal toxicity determinations (exposure time=2 hrs), **methyl ethyl ketone,** diluted with phosphate buffered saline, was tested at 18, 13 and 9ul/ml in the absence of metabolic activation, with cell survival ranging from 93.3% to 51.1% relative to the solvent control. Assays with metabolic activation were tested at 10, 8 and 6ul/ml (exposure time=2 hrs), with cell survival ranging from 85.7% to 67.3%. None of the tested concentrations produced significantly greater transformation frequencies ($p > 0.05$, Modified Poisson Distribution) relative to the solvent control.
[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Morphological Transformation Assay using BALB/3T3 Mouse Embryo Cells, Final Report, (1984), EPA Document No. 40-8444072, EPA Fiche No. OTS0507470] **UNREVIEWED**

An inhalation teratology study was conducted with pregnant Sprague-Dawley rats (25/group) receiving whole body exposure to **methyl ethyl ketone** in a dynamic air flow chamber, 7 hours/day on days 6 through 15 of gestation. There was no effect of treatment for all animals as indicated by clinical observations, absolute or relative liver weights, food consumption, number of pregnancies, and mortality. Maternal toxicity was evident by statistical differences between high dose groups and controls for: maternal body weights, maternal body weight gain and water consumption. The average number of live fetuses per litter, incidence of resorption rates, fetal body weight or crown-rump length were not significantly affected by treatment. Significant differences were observed between the fetuses of the control and high dose group for skeletal variations, but no significant external or soft-tissue alterations were observed in any of the fetuses of treated females.
[Dow Toxicology Research Laboratory; Teratologic Evaluation of Inhaled Methyl Ethyl Ketone in Rats, (1979), EPA Document No. 878210652, Fiche No. OTS0206178] **UNREVIEWED**

The ability of **methyl ethyl ketone** to induce specific locus mutations at the TK locus in cultured L5178Y mouse lymphoma cells (Mouse Lymphoma Mutagenicity Assay) was evaluated in the presence and absence of Aroclor-induced rat liver S9 metabolic activation. Based on preliminary toxicity tests, 10 nonactivated cultures treated with 12, 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2 and 0.89ul/ml were cloned, producing a range of 46 - 122% total growth. Ten S9-activated cultures treated with 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2, 0.89 and 0.67ul/ml were cloned, producing a range of 30 - 116% total growth. None of the cultures that were cloned produced mutant frequencies which were significantly greater than the mean mutant frequency of the solvent controls (DMSO, acetone).
[Microbiological Associates Inc.; L5178Y TK +/- Mouse Lymphoma Mutagenicity Assay, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone** was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538 (Ames Test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of the preliminary bacterial toxicity determinations, **methyl ethyl ketone,** diluted with DMSO, was tested for mutagenicity at concentrations up to 32 ul/plate (presence metabolic activation) and 16 ul/plate (absence metabolic activation) using the preincubation technique. **Methyl ethyl ketone** did not cause a reproducible positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Microbiological Associates, Inc.; Salmonella/Mammalian-Microsome Preincubation Mutagenicity Assay (Ames Test), (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone (**MEK) was evaluated in bacterial tester strains E. coli WP2 and WP2uvrA and Salmonella TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain JD1, both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, MEK, diluted with DMSO, was tested for mutagenicity at concentrations up to 4000 ug/plate in the bacterial tests and 5000 ug/plate in the yeast tests using the agar overlay method. MEK did not cause a positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Shell Sittingbourne Research Centre; Toxicity Studies with Chemical Solvents: Short-Term in Vitro Tests for Genotoxic Activity with Methyl Ethyl Ketone. (1982), EPA Document No. 878210125, Fiche No. OTS0206206] **UNREVIEWED**

Methyl ethyl ketone was evaluated for the ability to increase the incidence of micronucleated polychromatic erythrocytes in bone marrow of male and female CD-1 mice treated by single i.p. injection (Micronucleus Test). Groups of 10 mice (5 male, 5 female) were sacrificed 12, 24 and 48 hours following injection of **methyl ethyl ketone** in corn oil at a dose of 1.96 ml/kg body weight (calculated LD20 dose). The ratio of normochromatic to polychromatic erythrocytes were not significantly different ($p > 0.05$, ANOVA) in the treated groups compared with vehicle controls, regardless of sacrifice time. The incidence of micronucleated polychromatic erythrocytes was increased above the vehicle control 24 hours after administration, but was not considered statistically significant when compared to all treatment and vehicle control groups regardless of sacrifice time ($p > 0.05$, ANOVA).
[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Micronucleus Cytogenetic Assay in Mice, Final Report, (1984), EPA

Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The effects of **methyl ethyl ketone** were examined in the rat hepatocyte primary culture/DNA repair assay. Based on preliminary toxicity tests, **methyl ethyl ketone** was tested at concentrations of 5.0 (relative toxicity 74.67%), 2.5, 1.0, 0.5, 0.1 or 0.01 ul/ml (relative toxicity 6.67%). None of the tested concentrations caused a significant increase in unscheduled DNA synthesis over the solvent control (DMSO).
[Microbiological Associates Inc.; Unscheduled DNA Synthesis in Rat Primary Hepatocytes, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The ability of **methyl ethyl ketone** to cause chromosome aberrations was evaluated in cultured rat (strain not reported) liver cell line. Based on preliminary toxicity determinations, rat liver cultures were exposed to 250, 500 or 1000 ug/ml and incubated for 24 hours. Two hours prior to the end of incubation, colcemid was added and at the end of incubation period 100 cells from each culture were analyzed. No increase (statistical analysis not reported) in the frequency of chromatid gaps, chromatid breaks or total chromatid aberrations were observed in any of the cultures.

In rats exposed by inhalation to 1760 mg MEK/cu m (600 ppm), there were only marginal effects on microsomal cytochrome P-450 activities ... However, a daily dose of 1.4 mL MEK per kg for 3 days incr the amounts of ethanol- and phenobarbital-inducible cytochromes P-450 ...
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.53 (1993)]**PEER REVIEWED**

In a study on male Sprague-Dawley rats, pretreatment with MEK elevated total microsomal cytochrome P-450 and NADPH-dependent cytochrome-c-reductase, the rates of oxidation of N-nitrosodimethylamine, benzphetamine and pentoxyresorufin, and also the levels of immunoreactive protein for both P-450 isozymes ... In a study of hepatotoxicity in rats, ... found that MEK incr liver cytochrome P-450 content (33-86%) and glutathione-S-transferase (GST) activity (42-64%) but had no effect on serum glutamate dehydrogenase (GLDH) activity. ... studied the effects on hepatic cytochrome P-450 activities of repeated daily doses of 1.87 mL/kg given by gavage to male Fischer-344 rats. The activity of 7-ethoxy coumarin-O-deethylase was incr by up to 500% after 1 to 7 days of MEK treatment,

but there was practically no change in benzphetamine-N-demethylase activity. In another study in male Sprague-Dawley rats, admin of MEK by gavage cause an incr in hepatic acetanilide hydroxylase and a marginal incr in aminopyrine-N-demethylase activities ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.53 (1993)]**PEER REVIEWED**

MEK has been identified as a minor but normal constituent of urine ... serum and urine of diabetics ... and expired air ... . Its production in the body has been attributed to isoleucine catabolism ... studies ... indicate that the same metabolites are produced and excreted in humans as in experimental animals. ... further indicated that in an inhalation exposure to 590 mg MEK/cu m (200 ppm) the calculated areas under the curves of blood solvent concn versus time (AUC) for MEK and 2,3-butanediol were equal, which suggests that MEK is almost completely transformed to 2,3-butanediol. The bulk of MEK absorbed thus enters the general metabolism and is transformed to simple compounds like carbon dioxide and water.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.55 (1993)]**PEER REVIEWED**

Absorption, Distribution & Excretion:

Measurable (2.54 to 13 ug/l) quantities of **methyl ethyl ketone** appeared in expired air of adult humans 3 min following dermal exposure to 100 ml **methyl ethyl ketone** applied to 91.5 sq cm of skin.
[Wurster; J Pharm Sci 54: 554 (1965)]**PEER REVIEWED**

Ketones are readily absorbed through the intact skin. Usually they are rapidly excreted ... in the expired air. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1170]**PEER REVIEWED**

Workers occupationally exposed to **methyl ethyl ketone (**MEK) were examined. ... Workers exposed to 300 micrograms per liter MEK, the aveolar concn was 30% of the environmental concn. Lung uptake averaged 1.05 mg/min. The blood concn of MEK ranged from 842 to 9573 ug/l, with a mean of 2630 ug/l. Blood concn of MEK were strongly correlated with alveolar concn. MEK was more soluble in heart and muscle tissue than in lung tissue or fat. Urinary MEK excretion ranged from 120 to 1120 mg/l, with a mean of 487 mg/l. ... MEK was not persistent in the tissues. ... Urinary excretion of MEK and acetylmethylcarbinol are only around 0.1% of MEK lung absorption, the main pathway through which MEK is eliminated is unknown.
[Perbellini L et al; Intern Arch Occup Environ Health 54 (1): 73-81 (1984)]**PEER REVIEWED**

ALTHOUGH ABSORPTION ... THROUGH THE SKIN MAY OCCUR, IT HAS BEEN SHOWN THAT IT IS LOW IN TOXICITY BY THIS ROUTE.
[Patty, F. (ed.). Industrial Hygiene and Toxicology: Volume II: Toxicology. 2nd ed. New York: Interscience Publishers, 1963. 1732]**PEER REVIEWED**

Percutaneous absorption of MEK appears to be rapid ... MEK was present in the exhaled air of human subjects within 2.5-3.0 min after it was applied to normal skin of the forearm, and the concn of MEK in

exhaled air reached a plateau in 2-3 hr. The rate of absorption was controlled mainly by the moisture content of the skin. With dry skin, absorption was slow, and it took 4-5 hr for the concn of MEK in expired air to attain a plateau. With moist skin, absorption was very rapid initially. MEK was detected in expired air in measurable concn within 30 sec after an application of MEK to the forearm, and a max concn in expired air, averaging 4X the plateau level for normal and dry skin, was achieved in 10-15 min.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.49 (1993)]**PEER REVIEWED**

The absorption of MEK via the lungs was examined ... in a study of workers exposed in industrial workplace. The MEK concn in alveolar and expired air correlated significantly with the environmental concn, and averaged 30% of the latter. In more recent studies ... values for pulmonary absorption ranging from 41.1% to 55.8% were obtained. ... Deeper inhalation incr the alveolar volume relative to the dead space (the non-alveolar volume of the respiratory system), and thus incr the apparent absorption ... .

(1993)]**PEER REVIEWED**

Mechanism of Action:

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissue consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed. An enzyme associated metabolic damage with a concomitant impairment of axonal flow is discussed as a possible underlying pathomechanism.
[Schmidt R et al; Respiration 46 (4): 362-9 (1984)]**PEER REVIEWED**

There is very limited info on the mechanisms of toxic action of MEK. Relatively high inhaled concn 1,475-29,500 mg/cu m (500-10,000 ppm) caused pulmonary vasoconstriction and hypertension in cats and dogs ... From the toxicological point of view, interactions leading to the potentiation of effects, particularly neurotoxicity, by other intrinsically toxic substances constitute the main hazard of MEK. The mechanisms underlying these interactions are incompletely known ... .

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Methyl ethyl ketone's production and use as a solvent for coatings, resins, rubbers, plastics, pharmaceuticals, adhesives and rubber cements will result in its release to the environment through various waste streams. Its use as a starting material or intermediate in the manufacture of chemical products will also lead to its release to the environment. **Methyl ethyl ketone** occurs naturally as a metabolic byproduct of plants and animals and is released into the atmosphere by volcanoes and forest fires. Based on an experimental vapor pressure of 91 mm Hg at 25 deg C, **methyl ethyl ketone** is expected to exist solely as a vapor in the ambient atmosphere. Vapor-phase **methyl ethyl ketone** is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals with an estimated atmospheric half-life of about 14 days. This compound is also expected to undergo photolysis in the atmosphere by natural sunlight. Photochemical degradation of **methyl ethyl ketone** by natural sunlight is expected to occur at approximately 1/5 the rate of degradation by photochemically produced hydroxy radicals. **Methyl ethyl ketone** is expected to have very high mobility in soils based upon measured Koc values of 29 and 34 obtained in silt loams. Volatilization from dry soil surfaces is expected based upon the vapor pressure of this compound. Volatilization from moist soil surfaces is also expected based upon the measured Henry's Law constant of 4.7X10-5 atm-cu m/mol. The volatilization half-life of **methyl ethyl ketone** from silt and sandy loams was measured as 4.9 days. This compound is expected to biodegrade under aerobic and anaerobic conditions. In water, **methyl ethyl ketone** is not expected to adsorb to suspended solids or sediment based upon its measured Koc values. Volatilization from water surfaces is expected to be an important environmental fate process given its Henry's Law constant. Estimated half-lives for a model river and model lake are 19 and 197 hours, respectively. Bioconcentration in aquatic organisms is considered low based upon an estimated BCF value of 1. Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used. The general population may be exposed to **methyl ethyl ketone** through the use of commercially available products containing this compound such as paints, adhesives, and rubber cements. Exposure will also arise from inhalation of ambient air and ingestion of drinking water and food that contains **methyl ethyl ketone. (**SRC)

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,221,857 workers (201,308 of these are female) are potentially exposed to **methyl ethyl ketone** in the US(1). Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used(SRC). The 8 hour TWA exposure to **methyl ethyl ketone** was 45.4 ppm in a survey of 50 occupationally exposed male subjects working in a magnetic videotape producing factory(2). These workers had average concns of **methyl ethyl ketone** of 2 ppm and 1.4 mg/l in breath and blood samples respectively(2). The mean concn of **methyl ethyl ketone** in the breathing zones of 47 US plants using

polyurethane coatings was 4.33 ppm(3). **Methyl ethyl ketone** was detected in the breathing zones in 20 of 70 samples (mean concn 12 mg/cu m) obtained from autobody shops and spray paint shops in Australia(4).

[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982)]**PEER REVIEWED**

The kinetics of inhaled **methyl ethyl ketone (**MEK) in human volunteers was studied in an exposure chamber. Relative pulmonary uptake was about 53% throughout a 4 hr exposure period at 200 ppm. Blood MEK concentration rose steadily until the end of exposure. Repeated bicycle exercise increased the overall blood MEK level markedly in comparison to sedentary activity, with transient peaks in association with cycling; thus blood MEK concentration depended both on the rate of uptake and the amount taken up. Only 3% of the absorbed dose was excreted unchanged by exhalation. A well known metabolite of MEK, 2,3-butanediol, was detected in the urine with maximum rates of excretion at about 6 to 12 hr from the beginning of exposure. About 2% of the MEK dose taken up by the lungs was excreted in the urine as 2,3-butanediol. ... Elimination of MEK in blood appeared to exhibit two phases: the initial alpha-phase (T1/2= 30 min; kel alpha= 0.023) over the first post-exposure hour, followed by the terminal beta-phase (T1/2= 81 min; kel beta= 0.009).
[Liira J et al; Int Arch Occup Environ Health 60 (3): 195-200 (1988)]**PEER REVIEWED**

Worker exposures were investigated in April 1983 at the Hoover Company, North Canton, Ohio. ... Area and personal air samples for numerous contaminants were collected and nonionizing radiation levels were measured. ... General medical questionnaires and blood tests for **methyl ethyl ketone (**MEK) were given to exposed workers. ... No respiratory symptoms or pulmonary function disorders were identified in the foundry workers, and MEK was detected in the blood of only one worker at 1.4 ug/ml. ...

Environmental Fate:

TERRESTRIAL FATE: Measured Koc values of 29 and 34 were obtained for **methyl ethyl ketone** in silt loams(1). Based on a recommended classification scheme(2), **methyl ethyl ketone** is expected to have very high mobility in soil(SRC). Volatilization of **methyl ethyl ketone** from dry soil surfaces is expected based upon an experimental vapor pressure of 91 mm Hg at 25 deg C(3). Volatilization from moist soil surfaces(SRC) is also expected given the measured Henry's Law constant of 4.7X10-5 atm-cu m/mole(4). The volatilization half-life of **methyl ethyl ketone** from silt and sandy loams was measured as 4.9 days(5). **Methyl ethyl ketone** is expected to biodegrade under both aerobic and anaerobic conditions as indicated by numerous screening tests(6-9).

ATMOSPHERIC FATE: According to a model of gas/particle partitioning of semivolatile organic compounds in the atmosphere(1), **methyl ethyl ketone,** which has an experimental vapor pressure of 91 mm Hg at 25 deg C(2), will exist solely as a vapor in the ambient atmosphere. Vapor-phase **methyl ethyl ketone** is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals(SRC); the half-life for this reaction in air is estimated to be about 14(3,SRC) days. **Methyl ethyl ketone** is also expected to undergo photodecomposition in the atmosphere by natural sunlight(4,5). Photochemical degradation of **methyl ethyl ketone** by natural sunlight is expected to occur at approximately 1/5 the rate of degradation by photochemically produced hydroxyl radicals(5).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **methyl ethyl ketone** with photochemically-produced hydroxyl radicals has been measured as 1.15X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 14 days at an atmospheric concn of 5.0X10+5 hydroxyl radicals per cu cm(1,SRC). **Methyl ethyl ketone** is also expected to undergo photodecomposition in the atmosphere by natural sunlight(2,3). Based on the actinic fluxes within the planet boundary layer, along with an estimated quantum yield and absorption cross section, the rate of photodissociation of **methyl ethyl ketone** by natural sunlight is approximately 1/5 the rate of dissociation by hydroxyl radicals(3). This compound is not expected to undergo hydrolysis in the environment due to a lack of functional groups which hydrolyze(SRC).

Atmospheric Concentrations:

The presence of solvents such as toluene, xylene, **methyl ethyl ketone,** and other similar products in the indoor air of an automobile body repair shop, an offset printing facility and the adjacent dwellings was monitored, and the individual exposure of the corresponding workers and residents was tested by biological monitoring of exhaled breath and by personal air sampling. The concentrations of solvents tested in the air of both sites surveyed were lower than prevailing Dutch Maximum Allowable Concentration levels. The levels of solvents recorded in the air of apartments situated on top of the facilities surveyed were significantly higher than the levels recorded in the surrounding dwellings. The levels of **methyl ethyl ketone,** toluene and xylene in personal air samples of employees at the body shop were 1.5 times higher than in ambient air. The level of toluene in alveolar air of residents living above the automobile repair shop was 50 percent higher than that recorded in spot samples. The levels of other solvents were equal to or lower than the detection level. At the offset printing facility, toluene, xylene, butylacetate, 2-ethoxyethanol and cyclohexanone in air and in personal air samples followed the same general pattern identified for the body shop. In a dwelling next to the shop and in an apartment on top of the shop, the concentrations ranged from 3 to 9 percent and 14 to 19 percent, respectively, of the levels recorded inside the facility itself.

Environmental Standards & Regulations:

FIFRA Requirements:

Unless designated as an active ingredient in accordance with paragraph (b) or (c) of this section, this substance, when used in antimicrobial products, is considered inert, having no independent pesticidal

activity. The percentage of such an ingredient shall be included on the label in the total percentage of inert ingredients.
[40 CFR 162.60 (7/1/88)]**PEER REVIEWED**

Methyl ethyl ketone is exempted from the requirement of a tolerance when used as a solvent, cosolvent in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only.
[40 CFR 180.1001(d) (7/1/96)]**PEER REVIEWED**

Acceptable Daily Intakes:

... An Acceptable Daily Intake (ADI), defined as the amount of a chemical to which humans can be exposed on a daily basis over an extended period of time (usually a lifetime) without suffering a deleterious effect, for **methyl ethyl ketone** is 3.2 mg/day for oral exposure. ...
[USEPA; Health and Environmental Effects Profile for Methyl Ethyl Ketone p.80 (1988) EPA/600/X-85/363]**PEER REVIEWED**

TSCA Requirements:

Pursuant to section 8(d) of TSCA, EPA promulgated a model Health and Safety Data Reporting Rule. The section 8(d) model rule requires manufacturers, importers, and processors of listed chemical substances and mixtures to submit to EPA copies and lists of unpublished health and safety studies. **Methyl ethyl ketone** is included on this list.
[40 CFR 716.120 (7/1/96)]**PEER REVIEWED**

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 5000 lb or 2270 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/96)]**PEER REVIEWED**

RCRA Requirements:

U159; As stipulated in 40 CFR 261.33, when 2-**butanone**, as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).
[40 CFR 261.33 (7/1/96)]**PEER REVIEWED**

F005; When **methyl ethyl ketone** is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F005), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/96)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Methyl ethyl ketone** is produced, as an intermediate or final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/87)]**PEER REVIEWED**

Listed as a hazardous air pollutant (HAP) generally known or suspected to cause serious health problems. The Clean Air Act, as amended in 1990, directs EPA to set standards requiring major sources to sharply reduce routine emissions of toxic pollutants. EPA is required to establish and phase in specific performance based standards for all air emission sources that emit one or more of the listed pollutants. **Methyl ethyl ketone** is included on this list.

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: HIGHLY FLAMMABLE: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-127]**PEER REVIEWED**

Public safety: CALL Emergency Response Telephone Number. ... Isolate spill or leak area immediately for at least 25 to 50 meters (80 to 160 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the

Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, ISOLATE for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Fire: CAUTION: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency

Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Preventive Measures:

Work practices and industrial hygiene techniques should minimize the volatilization of ketones in the workroom air in order to ensure that the exposure limits are not exceeded. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1173]**PEER REVIEWED**

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without hazard. Use water spray to disperse vapors and dilute standing pools of liquid.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Evacuation: If material leaking (not on fire) consider evacuation from downwind area based on amount of material spilled, location and weather conditions.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Personnel protection: Avoid breathing vapors. Keep upwind. ... Do not handle broken packages without protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **methyl ethyl ketone/. ...** Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents

are highly flammable.
[Hart C; J Environ Health 49 (5): 282-6 (1987)]**PEER REVIEWED**

SRP: Local exhaust ventilation should be applied wherever there is an incidence of point source emissions or dispersion of regulated contaminants in the work area. Ventilation control of the contaminant as close to its point of generation is both the most economical and safest method to minimize personnel exposure to airborne contaminants.
PEER REVIEWED

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

SRP: Contaminated protective clothing should be segregated in such a manner so that there is no direct personal contact by personnel who handle, dispose, or clean the clothing. Quality assurance to ascertain the completeness of the cleaning procedures should be implemented before the decontaminated protective clothing is returned for reuse by the workers.
PEER REVIEWED

The worker should immediately wash the skin when it becomes contaminated.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

Work clothing that becomes wet should be immediately removed due to its flammability hazard.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

The International Air Transport Association (IATA) Dangerous Goods Regulations are published by the IATA Dangerous Goods Board pursuant to IATA Resolutions 618 and 619 and constitute a manual of industry carrier regulations to be followed by all IATA Member airlines when transporting hazardous materials.
[IATA. Dangerous Goods Regulations. 38th ed. Montreal, Canada and Geneva, Switzerland: International Air Transport Association, Dangerous Goods Board, January, 1997. 179]**PEER REVIEWED**

The International Maritime Dangerous Goods Code lays down basic principles for transporting hazardous chemicals. Detailed recommendations for individual substances and a number of recommendations for good practice are included in the classes dealing with such substances. A general index of technical names has also been compiled. This index should always be consulted when attempting to locate the appropriate procedures to be used when shipping any substance or article.
[IMDG; International Maritime Dangerous Goods Code; International Maritime Organization p.3080 (1988)]**PEER REVIEWED**

Cleanup Methods:

The Hazardous Materials Technical Center (HMTC), an EPA emergency response cleanup services contractor cleaned up a **methyl ethyl ketone (**MEK) spill and decontaminated the groundwater. The spill cleanup involved removing low concentrations of MEK from groundwater. The spill was caused by an overturned tank truck containing 7200 gallons of MEK. MEK was directed into four dry wells that served as primary storm drainage. Immediately after the incident, 6000 gallons of water were pumped from the dry well; 2400 gallons of MEK were recovered from the water. About 1500 gallons of MEK were removed from the truck, and the remaining 3300 gallons of MEK either vaporized or entered an unsaturated zone. MEK concentrations up to 2200 mg/l were reduced to 50 ug/l before reinjection. Levels of MEK in the sample wells, production wells, and reinjection wells were reduced to nondetectable levels.

Methyl ethyl ketone in biofluid samples is analyzed using headspace chromatography with a flame ionization detector. The relative retention time is 0.816 min (relative to n-propanol 1.50 min).
[Sunshine, Irving (ed.) Methodology for Analytical Toxicology. Cleveland: CRC Press, Inc., 1975.,p. VII/7]**PEER REVIEWED**

A method is described for the determination of the concn of **methyl ethyl ketone** and its metabolites: 2-butanol, 3-hydroxy-2-**butanone**, and the meso- and d,l-isomers of 2,3-butanediol in urine. The analytes were isolated from urine by solid-phase extraction and analyzed by capillary gas chromatography. The recovery rates were 50-70% for the 2,3-butanediol isomers and 88-96% for the other analytes. The precision of the method ranged 5-12% (standard deviation %). The detection limit was 1.0 and 1.4 mg/l for meso- and d,l 2,3-butanediol, respectively, and ranged 0.1-0.15 mg/l for the other analytes.

EPA Method 1624 - Volatile Organic Compounds By GC/MS: Grab samples in municipal and industrial discharges are collected. If residual chlorine is present, add sodium thiosulfate. Extraction is performed by a purge and trap apparatus. An isotope dilution gas chromatography/mass spectrometry method for the determination of volatile organic compounds in municipal and industrial discharges is described. Unlabeled **methyl ethyl ketone** has a minimum level of 50 ug/l and a mean retention time of 848 sec.
[40 CFR 136 (7/1/88)]**PEER REVIEWED**

EPA Method 8015: Nonhalogenated Volatile Organics. For the analysis of solid waste, a representative

sample (solid or liquid) is collected in a standard 40 ml glass screw-cap VOA vial equipped with a Teflon-faced silicone septum. Sample agitation, as well as contamination of the collected sample with air, must be avoided. Two VOA vials are filled per sample location, then placed in separate plastic bags for shipment and storage. Samples can be analyzed by direct injection or purge-and trap gas chromatography. A temperature program is used in the gas chromatograph to separate the organic compounds. Column 1 is an 8 ft by 0.1 in ID stainless steel or glass column packed with 1% SP-1000 on Carbopack-B 60/80 mesh or equivalent. Column 2 is a 6 ft by 0.1 in ID stainless steel or glass column packed with n-octane on Porasil-C 100/120 mesh (Durapak) or equivalent. Detection is achieved by a flame ionization detector (FID). Under the prescribed conditions, **methyl ethyl ketone** can be detected using this method. No statistical analysis was determined; specific method performance information will be provided as it becomes available.

Human Toxicity Excerpts:

HIGH ATM CONCN OF **METHYL ETHYL KETONE** IS IRRITATING TO THE EYES, NOSE, AND THROAT AND PROLONGED EXPOSURE MAY PRODUCE CNS DEPRESSION ... NO UNTOWARD EFFECTS HAVE BEEN REPORTED FOR CHRONIC EXPOSURE TO LOW CONCN. PROLONGED SKIN CONTACT MAY DEFAT THE SKIN AND PRODUCE DERMATITIS. IF SPLASHED IN THE EYES IT MAY PRODUCE PAINFUL IRRITATION AND CORNEAL INJURY.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

... WORKERS EXPOSED TO 300-500 PPM COMPLAINED OF HEADACHE, IRRITATION, AND NAUSEA. EXPOSURES TO 700 PPM LED TO NO PERMANENT UNTOWARD EFFECTS. MOMENTARY EXPOSURE TO 33,000 AND 100,000 PPM PRODUCED INTOLERABLE IRRITATION OF THE EYES, NOSE, AND THROAT.
[Clayton, G. D. and F. E. Clayton (eds.). Patty's Industrial Hygiene and Toxicology: Volume 2A, 2B, 2C: Toxicology. 3rd ed. New York: John Wiley Sons, 1981-1982. 4730]**PEER REVIEWED**

SHORT EXPOSURE OF WORKERS TO 500 PPM ... IN AIR PROVOKED NAUSEA AND VOMITING ... SEVERAL CASES OF PERIPHERAL NEUROPATHY ... OBSERVED /AFTER/ ACUTE PROLONGED OR REPEATED EXPOSURE. NEUROPATHY IS USUALLY SYMMETRICAL, PAINLESS WITH SENSORY LESIONS PREDOMINATING; IT MAY INVOLVE UPPER OR LOWER LIMBS; IN SOME CASES THE FINGERS HAVE BEEN AFFECTED FOLLOWING IMMERSION ... IN THE LIQUID. DERMATITIS ... REPORTED AFTER IMMERSION IN THE LIQUID AND AFTER EXPOSURE TO CONCN VAPORS. /KETONES/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1171]**PEER REVIEWED**

METHYL ETHYL KETONE IS IMPLICATED AS THE CAUSE OF RETROBULBAR NEURITIS IN PT WHO USED THE SOLVENT IN REMOVING PAINT FROM AN AIRPLANE HANGAR.
[BERG EF; ANN OPHTHALMOL 3 (12): 1351 (1971)]**PEER REVIEWED**

Exposure of the forearm for 1 hr/day for 6 consecutive days produced damage to the horny layer of the epithelium. ... **Methyl ethyl ketone** can defat and partially dehydrate the stratum corneum of human skin without producing irritation or inflammation.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A workman splashed his eye accidentally /with **methyl ethyl ketone/,** but the next day had only slight conjunctival hyperemia and no residual corneal injury. Despite the mildness of the injury, in the next few days the affected eye developed severe anterior uveitis triggered by slight trauma.

[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Toxic effects of common organic solvents on workers /were/ examined. The most notable acute effects of occupational exposure to organic solvents are /CNS depression/ and other nerve dysfunctions. The common symptoms of short term exposure are fatigue, headache, nausea, sleep disturbance, and alteration in memory. Psychomotor performance of adverse effects on intellectual or memory functions are demonstrated with psychological test batteries after long-term occupational exposure to organic solvents. The mutagenic, carcinogenic, and toxicological effects of ... **methyl ethyl ketone ...** are summarized. ... In clinical observations, the effects of organic solvents can cause increased excretion of abnormal cells and protein in urine. This indicates the possible correlation between long-term exposure and renal disease.
[Bang KM; Health Hazards in the Occupational Environment 7 (3): 15-29 (1984)]**PEER REVIEWED**

A case of contact urticaria (CU) caused by **methyl ethyl ketone (**MEK) was reported. ... A cotton swab test with MEK to the normal skin on his forearm caused the skin to turn bright red. The spot was itchy, but no induration or edema was noticed. The reaction reached its maximum after 15 minutes and then gradually faded. The test was repeated after two days with the same results. Application of the same grade MEK to five medical staff members produced no reaction. ... MEK should be added to the list of agents that are not only irritants, but can also cause contact urticaria.
[Varigos GA, Nurse DS; Contact Dermatitis 15 (4): 259-60 (1986)]**PEER REVIEWED**

... Has a low toxicity following both acute and chronic exposures.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1748]**PEER REVIEWED**

To determine whether unchanged solvent urinary concentration could be used as a biological exposure index, workers occupationally exposed to various solvents were studied. Nine unrelated groups (a total of 659 males) working in plastic boat, chemical, plastic button, paint, and shoe factories were studied. Urine samples were collected at the beginning of the workshift and at the end of the first half of the shift. A close relationship (correlation coefficient always above 0.85) between the average environmental solvent concentration (mg/cu m) measured in the breathing zone and the urinary concentration of unchanged solvent (ug/l) was observed.
[Ghittori S et al; Am Ind Hyg Assoc J 48 (9): 786-90 (1987)]**PEER REVIEWED**

... Seventy healthy male and female volunteers, 18 to 32 years old, with no previous prolonged exposure to solvents were exposed to 0 or 250 ppm acetone, 200 ppm MEK, or 125 ppm acetone plus 100 ppm MEK vapors for 4 hours in an exposure chamber. Expired air samples were collected before exposure, after 2 and 4 hours exposure, 90 minutes after exposure ended, and the next morning. Blood samples were collected on the day preceding exposure, at 2 or 4 hours of exposure, 2 hours after exposure ended, and the following day. Samples were analyzed for acetone and MEK by gas or gas/liquid chromatography. ... Blood MEK or acetone concentrations continued to increase throughout exposure, the increases between 2 and 4 hours being larger in the case of acetone. Acetone concentrations in the breath took longer to decrease than those of MEK. No interactive effects were noted in the combined exposures. Blood acetone and MEK concentrations were moderately correlated with their breath concentrations. Blood MEK and acetone concentrations tended to be lower in female subjects than in males; however, the differences were significant only for acetone in the combination exposure after 2 hours exposure and 90 minutes postexposure. ...
[Brown WD et al; The Changing Nature of Work and Workforce, Proceedings of the Third Joint US-Finish Science Symposium p.111-14 (1986)]**PEER REVIEWED**

A 47-yr old woman inadvertently ingested an unknown amt of MEK and was found unconscious, hyperventilating, and suffering from severe metabolic acidosis. Her plasma concn of MEK was 950 mg/L. She responded promptly to an infusion of sodium hydrogen carbonate and was discharged from the hospital after a wk. The metabolic effects of MEK ingestion by humans are not well characterized and it is uncertain that the acidosis was produced by MEK.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

... exposure to 266-797 mg/cu m (90-270 ppm) for up to 4 hr/day caused his subjects to underestimate times of 5 to 30 sec ... on the other hand, found that a 4-hr exposure of human subjects to 590 mg/cu m (200 ppm) had no significant effect in a variety of behavioral test. These included psychomotor, visual vigilance, dual task, sensorimotor and psychological tests. Solvent mixtures of 295 mg MEK/cu m (100 ppm) and 298 mg acetone/cu m (125 ppm) similarly had no significant effect on the results of these behavioral tests.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

MEK (0.1 mL) rubbed into volar forearm skin daily for 18 days and left uncovered did not produce persistent erythema or swelling ... A 5-min contact with 1.5 mL of analytical grade MEK confined to a 20-mm circle on the forearm produced a temporary whitening of the skin, but no visible erythema, alteration in cutaneous blood flow or other indication of irritation to the skin ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.81 (1993)]**PEER REVIEWED**

Long-term exposure of 51 Italian workers to MEK produced indications of neurotoxicity with slightly, but not significantly, reduced nerve conduction velocities and various other symptoms such as headache, loss of appetite and weight, GI upset, dizziness, dermatitis and muscular hypotrophy, but no clinically recognizable neuropathy. ... There has been a brief report of chronic exposure of American workers, in a factory producing coated fabric, to 885-1770 mg MEK/cu m (300-600 ppm) in the apparent absence of other solvents. ... Workers complained of dermatoses and numbness of fingers and arms.

[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.82 (1993)]**PEER REVIEWED**

In a historical prospective morality study of 446 male workers in two MEK dewaxing plants, with an average follow up of 13.9 years, the observed deaths (46) were below the expected (55.51). There was a slight deficiency of deaths from neoplasms (13 observed; 14.26 expected) but there was a significant incr of deaths from tumors of the buccal cavity and pharynx (2 observed; 0.13 expected). However, there were significantly fewer deaths from lung cancer (1 observed; 6.02 expected). In view of the small numbers, it was concluded that there was no clear evidence of cancer hazard in these workers ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.89 (1993)]**PEER REVIEWED**

The application of MEK to the forearm skin of two volunteers for 1 hr/day on six successive days damaged only the stratum corneum and that the dermal toxicity was similar to ethanol. Opdyke indicated that the application of 20 percent MEK in petrolatum to human forearm skin for 48 hr did not cause any irritation and that no sensitization reactions occurred when the same concentration was tested on 24 volunteers.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

Two cases of acute poisoning in a raincoat manufacturing operation where the seams were waterproofed with a resin dissolved in either acetone or MEK were reported. Samples of the workroom air indicated that the MEK concentration ranged from 398 to 561 ppm, whereas the acetone concentration ranged from 330 to 495 ppm. Two female employees were reportedly affected by the solvent vapors on different occasions. The first complained of stomach distress and watery eyes one morning, and later was found unconscious in a rest room. The employee had a strong acetone odor on her breath, but no acetonuria upon admission to the local hospital. She was treated with a CNS stimulant and awoke immediately, but complained of a severe headache. The patient was discharged from the hospital on the day following admission. The second case followed the first one by 1 day and was apparently less severe. The individual fainted and convulsed at the work site but regained consciousness immediately afterwards. At the hospital she was confused and had a headache, but after 1 hr of observation she was allowed to return home.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case study where a male patient attempted suicide by ingesting approximately 100 ml of an adhesive cement that contained 39 percent cyclohexanone, 28% MEK, 18% acetone was presented. The individual reportedly drank about 720 ml of sake (10 percent ethanol) 30 min prior to drinking the adhesive solution. The patient was unconscious when taken to a hospital about 2 hr after the ingestion of the solvent mixture. Gastric lavage, plasma exchange, and charcoal hemoperfusion were all performed, and the patient regained consciousness about 7 hr after ingestion; however, signs of systemic toxicity persisted. High blood concentrations of a cyclohexanone metabolite (cyclohexanal) were thought to be responsible for the coma, whereas the hyperglycemia was attributed to acetone.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New

York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of retrobulbar neuritis in a sailor who was using large quantities of MEK as a paint remover was reported. The affected individual complained of blurred vision, light-headedness, and nausea after being exposed to MEK vapor for 1.5 hr. Upon admission to a military hospital, the patient's near- and far-field visual acuity was reduced and blind spots were markedly enlarged when a white target was viewed. An ophthalmoscopic examination, however, did not reveal any abnormalities. Clinical testing on the day of admission revealed elevations in blood methanol and formaldehyde. Visual acuity returned to normal within 2 days of admission; however, the blood methanol levels did not return to normal until the sixth day of hospitalization. /It was/ concluded that MEK was the causative agent for the optic nerve damage that was observed. The MEK was assumed to have been systemically absorbed both dermally and through the lungs and then partially metabolized to methanol, which subsequently affected the optic nerve and cerebral cortex.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1767]**PEER REVIEWED**

A case of toxic encephalopathy with dementia and cerebellar ataxia in a 38-year-old male who spray-painted a truck in an unventilated garage with a paint that contained toluene, MEK, and propylene glycol. As time passed following the exposure, the individual began to experience memory problems along with headaches, shortness of breath, appetite and sleep disturbances, ataxia, and suicidal depression. Neuropsychological evaluations over a 2.5 year period revealed distinct cognitive, motor, and behavioral changes.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1769]**PEER REVIEWED**

The pharmacokinetics of MEK in 70 male and female volunteers following a 4-hr inhalation exposure either alone (200 ppm) or in combination with acetone (225 ppm, 1:1.25 ratio) was described. Blood and expired air elimination data for the MEK-exposed individuals revealed on average that (1) MEK steady-state breath levels of about 10 to 12 ppm were attained, (2) non-steady-state peak blood levels of 3 to 4 ug/ml occurred, (3) no significant difference in uptake or elimination was observed for males and females, and (4) no appreciable interaction affecting elimination took place with the combined exposures.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1769]**PEER REVIEWED**

[Arena, J.M. and Drew, R.H. (eds.) Poisoning-Toxicology, Symptoms, Treatments. 5th ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 358]**PEER REVIEWED**

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,221,857 workers (201,308 of these are female) are potentially exposed to **methyl ethyl ketone** in the US(1). Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used(SRC). The 8 hour TWA exposure to **methyl ethyl ketone** was 45.4 ppm in a survey of 50 occupationally exposed male subjects working in a magnetic videotape producing factory(2). These workers had average concns of **methyl ethyl ketone** of 2 ppm and 1.4 mg/l in breath and blood samples respectively(2). The mean concn of **methyl ethyl ketone** in the breathing zones of 47 US plants using polyurethane coatings was 4.33 ppm(3). **Methyl ethyl ketone** was detected in the breathing zones in 20 of 70 samples (mean concn 12 mg/cu m) obtained from autobody shops and spray paint shops in Australia(4).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983) (2) Sia Gl et al; Environ Monit Assess 19: 401-11 (1991) (3) Myer HE et al; Am Ind Hyg Assoc J 54: 663-70 (1993) (4) Winder C, Turner PJ; Ann Occup Hyg 36: 385-94 (1992)]**PEER REVIEWED**

The general population may be exposed to **methyl ethyl ketone** through the use of commercially available products containing this compound such as paints, adhesives, and rubber cements(SRC). Exposure will also arise from inhalation of ambient air, ingestion of drinking water and food that contains **methyl ethyl ketone(**SRC). The average blood concn of **methyl ethyl ketone** in 600 non-occupationally exposed individuals in the US was 7.1 ppb(1).

Body Burden:

Detected in 5 of 8 samples of mother's milk from 4 USA urban areas.
[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982)]**PEER REVIEWED**

The kinetics of inhaled **methyl ethyl ketone (**MEK) in human volunteers was studied in an exposure chamber. Relative pulmonary uptake was about 53% throughout a 4 hr exposure period at 200 ppm. Blood MEK concentration rose steadily until the end of exposure. Repeated bicycle exercise increased the overall blood MEK level markedly in comparison to sedentary activity, with transient peaks in association with cycling; thus blood MEK concentration depended both on the rate of uptake and the amount taken up. Only 3% of the absorbed dose was excreted unchanged by exhalation. A well known metabolite of MEK, 2,3-butanediol, was detected in the urine with maximum rates of excretion at about 6 to 12 hr from the beginning of exposure. About 2% of the MEK dose taken up by the lungs was excreted in the urine as 2,3-butanediol. ... Elimination of MEK in blood appeared to exhibit two phases: the initial alpha-phase (T1/2= 30 min; kel alpha= 0.023) over the first post-exposure hour, followed by the terminal beta-phase (T1/2= 81 min; kel beta= 0.009).
[Liira J et al; Int Arch Occup Environ Health 60 (3): 195-200 (1988)]**PEER REVIEWED**

Worker exposures were investigated in April 1983 at the Hoover Company, North Canton, Ohio. ... Area and personal air samples for numerous contaminants were collected and nonionizing radiation levels were measured. ... General medical questionnaires and blood tests for **methyl ethyl ketone (**MEK) were given to exposed workers. ... No respiratory symptoms or pulmonary function disorders were identified in the foundry workers, and MEK was detected in the blood of only one worker at 1.4 ug/ml. ...

The following Overview, *** KETONES ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- ACUTE EXPOSURE (ORAL) - Most available information concerns inhalational or dermal exposure. A few cases involving ingestion of **methyl ethyl ketone (**and co-ingestants) or ketone peroxide (with co-ingestants) have resulted in CNS depression, respiratory depression or corrosive effects and sequelae.
- ACUTE INHALATION - The effects vary, depending on extent and duration of exposure. Eye, nose and throat irritation, nausea, headache, vertigo, incoordination, CNS depression, narcosis and cardiorespiratory failure can occur. In most cases, recovery is usually rapid and complete.
- CHRONIC EXPOSURE - The major concern with chronic exposure is axonal neuropathy with secondary myelin damage; usually manifested as paresthesias and muscle weakness. Only six-carbon, linear chain ketones metabolized to gamma-diketones (such as methyl n-butyl ketone) are implicated.
- EYE EXPOSURE - Splash contact causes irritation, which may be slight, moderate, or severe, depending on the ketone. Vapors can cause irritation and lacrimation.

- ROUTES OF EXPOSURE - Ketones are absorbed by ingestion, inhalation, and dermal exposure.
- RELATED COMPOUNDS - Exposure to ketone solvents (**methyl ethyl ketone,** methyl isobutyl ketone, etc) must be distinguished from exposure to the peroxides of these same ketones. KETONE PEROXIDES are highly reactive and corrosive. Management of ketone peroxide exposure is discussed in a separate document.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Splash contact causes irritation, which may be slight, moderate, or severe, depending on the specific ketone; vapors may cause irritation and lacrimation.

CARDIOVASCULAR

0.2.5.1 ACUTE EXPOSURE

- Tachycardia may occur.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Ingestion of significant amounts may cause respiratory depression. Inhalation exposure may produce an anesthetic type of respiratory depression, dyspnea, and gasping. Pulmonary aspiration may result in chemical pneumonitis.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute inhalation exposure causes a progression of CNS effects, from headache, vertigo, incoordination, narcosis, dizziness, and tremor, to coma. Peripheral neuropathy has been reported following exposure to methyl-n-butyl ketone and 2,5-hexanedione. Trimethylnonanone is not associated with narcosis.
- Chronic exposure causes axonal neuropathy with secondary myelin damage, usually manifested as paresthesias and muscle weakness. Only six-carbon, linear chain ketones metabolized to gamma-diketones (such as methyl n-butyl ketone) are implicated.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Nausea and vomiting may occur.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Ketones may potentiate the hepatotoxicity of halogenated hydrocarbons. They may also inhibit aromatic hydrocarbon metabolism.

ACID-BASE

0.2.11.1 ACUTE EXPOSURE

- Metabolic acidosis has been reported.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Skin exposure to the liquid or vapor may result in dermatitis and paresthesias of affected areas. Contact urticaria has also been reported.

REPRODUCTIVE HAZARDS

- Limited studies have generally documented little or no effect of ketones on reproduction in experimental animals. Human data is lacking. 2,5-Hexanedione has an effect on spermatogenesis in male experimental animals.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- The ketones are generally unclassified by IARC. Those agents evaluated by IARC have been classified as having insufficient evidence to determine human carcinogenicity.

0.2.21.2 HUMAN OVERVIEW

- No adequate human studies exist for the agents in this category.

0.2.21.3 ANIMAL OVERVIEW

- Experimental animal studies are limited, but are generally negative, and agents in this group have little mutagenic activity.

GENOTOXICITY

- Extremely limited data is available for this class of agents. For many specific ketones, no data is available. Some studies report positive findings, but this category of agents appears to be generally non-mutagenic or only weakly mutagenic.

Laboratory:

- Plasma ketone levels are not clinically useful.
- If pulmonary aspiration is suspected, monitor chest x-ray and arterial blood gases or pulse oximetry.

Treatment Overview:

ORAL EXPOSURE

- With ingestion of small amounts the major concern is pulmonary aspiration and gastrointestinal decontamination is not recommended. With ingestion of large amounts there is potential for systemic toxicity from gastrointestinal absorption and GI decontamination is suggested, keeping in mind that pulmonary aspiration is still a concern.
- If the patient is obtunded, seizing, or has significant alterations in mental status, a cuffed endotracheal tube should be inserted prior to gastric aspiration.
  1. For moderate ingestions (less than 100 milliliters) activated charcoal alone is recommended.
  2. For large ingestions that have occurred within the past hour, careful gastric aspiration followed by activated charcoal is recommended.
     a. The lavage tube should be flexible, well lubricated with a water soluble gel to minimize gagging and vomiting, and of a large enough diameter to minimize vomiting of gastric contents around the tube and potential pulmonary aspiration.
     b. After the tube is in place, evacuate gastric contents rapidly. Repeated instillation of fluid to wash out the stomach is NOT suggested as it probably does not significantly enhance the removal of liquids and may enhance the potential for pulmonary aspiration.
     c. Instill activated charcoal prior to withdrawing the tube.
     d. For ingestions that have occurred more than 2 hours ago, gastric decontamination is not likely to be of benefit and is generally not warranted.
- Administer activated charcoal for moderate or large ingestions.
  1. ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- ACIDOSIS - Correct severe acidosis (pH < 7.1) with intravenous sodium bicarbonate. About 1 to 2 milliequivalents/kilogram is a useful starting dose. Monitor arterial blood gases to guide bicarbonate therapy.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor

for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
- Treat dermal irritation or burns with standard topical therapy. Patients developing dermal hypersensitivity reactions may require treatment with systemic or topical corticosteroids or antihistamines.

Range of Toxicity:

- The minimal toxic or lethal dose is variable and not well defined. Toxic effects following inhalation exposure depend on air concentration, time of exposure and underlying diseases.
- Exposure to airborne concentrations greater than 300 ppm of **methyl ethyl ketone** may result in discomfort and CNS depression. Methyl-isobutyl ketone produces irritation at an airborne concentration of 100 ppm (Hjelm et al, 1990).

[Rumack BH: POISINDEX(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001. Hall AH & Rumack BH (Eds):TOMES(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001.]
PEER REVIEWED

Antidote and Emergency Treatment:

For immediate first aid: Ensure that adequate decontamination has been carried out. If victim is not breathing, start artificial respiration, preferably with a demand-valve resuscitator, bag-valve-mask device, or pocket mask as trained. Perform CPR if necessary. Immediately flush contaminated eyes with gently flowing water. Do not induce vomiting. If vomiting occurs, lean patient forward or place on left side (head-down position, if possible) to maintain an open airway and prevent aspiration. Keep victim quiet and maintain normal body temperature. Obtain medical attention. /Ketones and related compounds/
[Bronstein, A.C., P.L. Currance; Emergency Care for Hazardous

Materials Exposure. 2nd ed. St. Louis, MO. Mosby Lifeline. 1994. 237]**PEER REVIEWED**

For basic treatment: Establish a patent airway. Suction if necessary. Watch for signs of respiratory insufficiency and assist ventilations if necessary. Administer oxygen by nonrebreather mask at 10 to 15 L/min. Monitor for pulmonary edema and treat if necessary. ... For contamination, flush eyes immediately with water. Irrigate each eye continuously with normal saline during transport. ... Do not use emetics. For ingestion, rinse mouth and administer 5 mL/kg up to 200 mL of water for dilution if the patient can swallow, has a strong gag reflex, and does not drool. Administer activated charcoal ... . /Ketones and related compounds/

Non-Human Toxicity Excerpts:

THE SINGLE DOSE ORAL TOXICITY ... HAS BEEN DETERMINED TO BE 3.3 G/KG ... FOR RATS. MASSIVE DOSES MAY BE EXPECTED TO RESULT IN IRRITATION OF THE LUNG & ... /CNS DEPRESSION/.
[Patty, F. (ed.). Industrial Hygiene and Toxicology: Volume II: Toxicology. 2nd ed. New York: Interscience Publishers, 1963. 1732]**PEER REVIEWED**

Guinea pigs exposed to 3300 ppm for 13.5 hr showed no signs of intoxication. Exposure to 10,000 ppm for a similar period produced irritation of the eyes and nose within 4 min and /CNS depression/ between 4-5 hr. Exposure to 33,000 ppm for 200 min produced /CNS depression/ and death. Exposure to 100,000 ppm for 45-55 min produced /CNS depression/ after 10 min.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1753]**PEER REVIEWED**

Exposure /of rats/ to 2000 ppm /for 2 hr/ showed no apparent toxicity. Exposure to 8000 ppm killed 3 of 6 rats in 8 hr, while 16,000 ppm for 1 hr caused death of all the animals.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1753]**PEER REVIEWED**

EXPOSURE TO 1500 PPM OF **METHYL ETHYL KETONE (**MEK) ALONE FOR 7-9 WK DID NOT CAUSE PARALYSIS BUT DID ELEVATE PLASMA CHOLINESTERASE LEVELS IN MICE, RATS, & CHICKENS.
[COURI D ET AL; PROC ANNU CONF ENVIRON TOXICOL, 5TH, AMRL-TR-74-125: 109 (1974)]**PEER REVIEWED**

ANALYSIS OF PORPHYRIN CONTENT OF MURINE ERYTHROLEUKEMIA (MEL) CELLS INCUBATED WITH 2-**BUTANONE** SHOWED THAT INCR HEMOGLOBIN SYNTH WAS ACCOMPANIED BY ACCUM OF PORPHYRINS.

[EBERT PS ET AL; CHEM BIOL INTERACT 36 (1): 61 (1981)]**PEER REVIEWED**

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissues consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed.
[Schmidt R; Respiration 46 (4): 62-9 (1984)]**PEER REVIEWED**

METHYL ETHYL KETONE DELAYED MATCH-TO-SAMPLE DISCRIMINATION TASK IN THE JUVENILE BABOON & ALSO SLOWED RESPONSE TIMES & INCR EXTRA RESPONSES.
[GELLER I; NEUROBEHAV TOXICOL 1 (SUPPL 1): 9 (1979)]**PEER REVIEWED**

METHYL ETHYL KETONE WAS EVALUATED FOR EFFECTS ON A DELAYED MATCH TO SAMPLE DISCRIMINATION TASK IN THE JUVENILE BABOONS. THE ANIMALS WERE EXPOSED TO HALF THE THRESHOLD LIMIT VALUE (245 MG/CU M) FOR 24 HR PER DAY DURING A 7 DAY PERIOD. EACH EXPOSURE CONDITION AFFECTED ACCURACY OF PERFORMANCE MINIMALLY BUT RESULTED IN INCREASED AND DECREASED EXTRA RESPONSES DURING THE DELAY INTERVALS.
[GELLER I; PHARMACOL BIOCHEM BEHAV 11 (4): 401-6 (1979)]**PEER REVIEWED**

Intraperitoneal injection of 750, 1500 or 2000 mg/kg **methyl ethyl ketone** to guinea pigs resulted in elevated serum ornithine carbamyl transferase (OCT) activity at the highest dose, where one of four animals died, and deposition of lipids in the liver with either 1500 or 2000 mg/kg was found.
[DiVincenzo GD et al; Am Ind Hyg Assoc J 34: 329 (1974)]**PEER REVIEWED**

Incubation of Ehrlich-Landschutz diploid ascites tumor cells in media containing 50 and 100 ppm **methyl ethyl ketone** resulted in the destruction of 10.5 and 14.0% of the cells. Control incubations lost only 4.2% of cells in the 5 hr period.
[Holmberg; Environ Res 7: 183 (1974)]**PEER REVIEWED**

Mutagenicity screening in Escherichia coli WP2, and Salmonella typhimurium strains TA1535, TA1537, TA1536 and TA1538 was negative.
[Smirasu Y; J Environ Poll Control 12: 407 (1976)]**PEER REVIEWED**

Pregnant rats inhaled 0, 400, 1000, or 3000 ppm of **methyl ethyl ketone** for 7 hr/day on days 6-15 of gestation. Maternal toxicity evidenced by decreased weight gain and increased water consumption was seen among rats exposed to 3000 ppm. Fetotoxicity (increased incidence of 2 minor skeletal variants) was observed among litters of rats exposed to 3000 ppm.
[Deacon MM et al; Toxicol Appl Pharmacol 59 (3): 620-2 (1981)]**PEER REVIEWED**

Groups of rats were exposed to 100 ppm hexane, 200 ppm **methyl ethyl ketone (**MEK), or fresh air in an exposure chamber 12 hr daily for 24 weeks. Body weight, motor nerve conduction velocity, distal motor

latency, and mixed conduction velocities were measured before exposure and after 4, 8, 12, 16, 20, and 24 wk exposure. ... Exposure to 200 ppm MEK significantly increased motor nerve conduction velocity, and mixed conduction velocities and decreased distal motor latency after 4 week exposure; but at a later stage no significant changes were found. Mixed exposure to 100 ppm hexane and 200 ppm MEK significantly decreased distal motor latency after 4 week exposure and decreased motor nerve conduction velocity and mixed conduction velocities after 20 and 24 week exposure.
[Takeuchi Y et al; Br J Ind Med 40 (2): 199-203 (1983)]**PEER REVIEWED**

Groups of Sprague-Dawley rats were exposed, by inhalation to ... **methyl ethyl ketone (**800 ppm, 2345 mg/cu m) ... for 4 weeks. Increased liver weights and liver-to-body weight ratios were observed. **Methyl ethyl ketone** depressed the formation of 2 metabolites of androstenedione but did not alter the concentration of cytochrome p450 in companion in vitro microsomal metabolism studies.
[Toftgard R et al; Scand J Work Environ Health 7 (1): 31-7 (1981)]**PEER REVIEWED**

Vapors in concn of 1000 ppm or 3000 ppm were embryotoxic and fetotoxic in rats causing acaudia, imperforate anus, and brachygnathia, as well as retardation of fetal development.
[Gosselin, R.E., R.P. Smith, H.C. Hodge. Clinical Toxicology of Commercial Products. 5th ed. Baltimore: Williams and Wilkins, 1984.,p. II-185]**PEER REVIEWED**

Testing of a drop on rabbit eyes indicates moderate reversible injury, graded 5 on a scale of 1-10. The compound was tested externally on the eyes of rabbits, and, according to the degree of injury observed after 24 hours, rated on a scale of 1 to 10. The most severely injurious substances have been rated 10.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Male and female Fischer 344 rats were exposed to 0, 1250, 2500, or 5000 ppm **methyl ethyl ketone (**MEK) vapors 6 hr/day, 5 day/wk for 90 days. The 90 day exposures had no adverse effect on the clinical health or growth of male or female rats except for a depression of mean body wt in the 5000 ppm exposure group. The 5000 ppm animals had a slight but significant increase in liver weight, liver weight/body weight ratio, and liver weight/brain weight ratio at necropsy. Serum glutamic-pyruvic transaminase (SGPT) activity in the 2500 ppm female rats was elevated while the 5000 ppm female rats exhibited significantly decreased serum glutamic-pyruvic transaminase SGPT activity. In addition, alkaline phosphatase, potassium, and blood glucose values for the 5000 ppm female rats were increased. ...

Chinese hamsters were exposed to ... **methyl ethyl ketone ...** known to be a strong inducer of aneuploidy in the yeast Saccharomyces cerevisiae. ... Solvent yielded negative results in the micro-nucleus test.
[Basler A; Mutat Res 174 (1): 11-13 (1986)]**PEER REVIEWED**

... Cultures of mature organotypic cord ganglia were extracted from fetal mouse spinal cord with the attached dorsal root. MEK at 300 ug/ml nutrient fluid was added to cultures for periods of up to 7 weeks. Cultures were examined under microscope twice weekly for morphological changes and were sampled at 3, 5, and 7 weeks for electron microscopy. Treated cultures remained viable for the 7 week exposure

period. After 6 to 7 weeks of exposure, distinct intraaxonal inclusion occurred along proximal and distal internodes of occasional sensory peripheral nerves (PNS). The structures lengthened and darkened throughout the exposure period and were often associated with axoplasmic granularity. The earliest change in cytoplasm was dispersion of Nissl bodies, which resulted in excessive numbers of free ribosomes or polyribosomal changes. There was a distension of neuronal cisternal systems. By week 5 there were abnormal amounts of smooth or agranular endoplasmic reticulum which appeared swollen with a translucent material. A swollen agranular recticulum was often associated with foci of axoplasmic debris. By week 7, intra-axonal cores of debris and myelin whorls were documented in 25% of the central nervous system and sensory perpipheral nerves axons examined ultrastucturally. ...

Chemical test results for cytogenetic effects in Chinese hamster ovary cells ... were negative for both chromosome aberrations and sister chromatid exchanges.
[NTP; Fiscal Year 1987 Annual Plan p.87 (1987) NTP-87-001]**PEER REVIEWED**

An oral dose of 1.5 g/kg to rats resulted in a 63% incr in liver triglycerides after 16 to 23 hr, but did not alter liver histology or incr either of two enzymes, serum glutamic-pyruvic transaminase (alanine transferase (ALT)) and hepatic glucose-6-phosphatase ... Much smaller acute ip doses (0.049 to 0.194 g/kg) to rats appeared not to damage the liver. A single oral dose (15 mmol/kg) of MEK did not affect the hepatobiliary function of rats over an observation period of 10 to 96 hr. ... A graded series of single doses of MEK to guinea-pigs revealed high sensitivity to small changes in dosage. The low dose (0.75 g/kg) appeared to produce no liver damage, whereas 1.5 g/kg produced slight liver damage and 2.0 g/kg produced major liver damage. These results also suggest that guinea-pigs and rats may be equally sensitive to MEK in terms of liver damage even though guinea-pigs survive acute exposure to higher concn of MEK vapor than do rats ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.58 (1993)]**PEER REVIEWED**

Consistent incr in the frequency of food-reinforced lever pressing by rats were detected at MEK exposures as low as 74 mg/cu m (25 ppm) for 2 hr. ... Vestibulo-ocular effects were detected during continuous iv admin of MEK for 1 hr via the caudal vein at a dosage as low as 0.005 g/kg/min ... this dosage is roughly equivalent to inhalation of 2,700 mg/cu m (900 ppm). ... Exposure of mice to 885 mg/cu m (300 ppm) for 30 min did not significantly alter schedule-controlled responses, whereas concn-related suppression of response occurred at consecutive incr concn (for 30 min) ranging from 2,950 to 29,500 mg/cu m (1,000 to 10,000 ppm) ... .

[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.96 (1993)]**PEER REVIEWED**

The developmental effects observed at an MEK vapor concentration of 3000 ppm were reexamined. Pregnant Sprague-Dawley rats were exposed to 400, 1000, or 3000 ppm of MEK for 7 hr/day on days 6 to 15 of gestation. There were no effects on maternal liver weight; however, a significant decrease in maternal body weight gain was observed in the animals exposed to 3000 ppm of MEK. In addition, none of the exposures affected the pregnancy rate, the number of implantations or fetal resorptions, the litter size, or the fetal body weight. Unlike the initial study, there were no gross or soft-tissue malformations at any exposure level; however, the 3000-ppm exposure caused a significant increase in the incidence of delayed skeletal ossifications (skull and neck) and an increase in the incidence of extra lumbar ribs. /It was/ concluded that MEK was not embryotoxic or teratogenic and only slightly fetotoxic in the rat at exposure concentrations of 3000 ppm.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1759]**PEER REVIEWED**

Groups of pregnant and nonpregnant mice were exposed to MEK vapor concentrations of 400, 1000, or 3000 ppm for 7 hr/day for 10 consecutive days (for pregnant mice, days 6 to 15 of gestation). The nonpregnant and pregnant mice showed no differences in sensitivity to the MEK exposures. The maternal body weight gain, extragestational weight gain, uterine weight, pregnancy rate, and implantation ratio were not affected by exposure to MEK vapors relative to control. The 3000-ppm exposure did, however, result in a relative increase in maternal liver and kidney weight. The percentage of live fetuses, resorptions, and dead fetuses per litter was also unaffected by the treatment. A concentration-related decrease in fetal weight was observed for both the male and females. Although there were no statistically significant increases in the number of malformed fetuses per litter, there were several atypical malformations (cleft palate, fused ribs, missing vertebrae, and syndactyly) not often found in control litters. A statistically significant increase in the incidence of misaligned sternebrae was observed in the fetuses exposed to 3000 ppm of MEK. No developmental or maternal effects were observed at vapor concentrations of 1000 ppm or less. After considering the results from the present study together with results obtained in rats, the authors concluded that MEK vapors caused mild developmental toxicity at concentrations that caused maternal toxicity.

TSCA Test Submissions:

The ability of **methyl ethyl ketone** to induce morphological transformation in the BALB/3T3 mouse cell line (Cell Transformation Assay) was evaluated both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary clonal toxicity determinations (exposure time=2 hrs), **methyl ethyl ketone,** diluted with phosphate buffered saline, was tested at 18, 13 and 9ul/ml in the absence of metabolic activation, with cell survival ranging from 93.3% to 51.1% relative to the solvent control. Assays with metabolic activation were tested at 10, 8 and 6ul/ml (exposure time=2 hrs), with cell survival ranging from 85.7% to 67.3%. None of the tested concentrations produced

significantly greater transformation frequencies (p > 0.05, Modified Poisson Distribution) relative to the solvent control.
[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Morphological Transformation Assay using BALB/3T3 Mouse Embryo Cells, Final Report, (1984), EPA Document No. 40-8444072, EPA Fiche No. OTS0507470] **UNREVIEWED**

An inhalation teratology study was conducted with pregnant Sprague-Dawley rats (25/group) receiving whole body exposure to **methyl ethyl ketone** in a dynamic air flow chamber, 7 hours/day on days 6 through 15 of gestation. There was no effect of treatment for all animals as indicated by clinical observations, absolute or relative liver weights, food consumption, number of pregnancies, and mortality. Maternal toxicity was evident by statistical differences between high dose groups and controls for: maternal body weights, maternal body weight gain and water consumption. The average number of live fetuses per litter, incidence of resorption rates, fetal body weight or crown-rump length were not significantly affected by treatment. Significant differences were observed between the fetuses of the control and high dose group for skeletal variations, but no significant external or soft-tissue alterations were observed in any of the fetuses of treated females.
[Dow Toxicology Research Laboratory; Teratologic Evaluation of Inhaled Methyl Ethyl Ketone in Rats, (1979), EPA Document No. 878210652, Fiche No. OTS0206178] **UNREVIEWED**

The ability of **methyl ethyl ketone** to induce specific locus mutations at the TK locus in cultured L5178Y mouse lymphoma cells (Mouse Lymphoma Mutagenicity Assay) was evaluated in the presence and absence of Aroclor-induced rat liver S9 metabolic activation. Based on preliminary toxicity tests, 10 nonactivated cultures treated with 12, 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2 and 0.89ul/ml were cloned, producing a range of 46 - 122% total growth. Ten S9-activated cultures treated with 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2, 0.89 and 0.67ul/ml were cloned, producing a range of 30 - 116% total growth. None of the cultures that were cloned produced mutant frequencies which were significantly greater than the mean mutant frequency of the solvent controls (DMSO, acetone).
[Microbiological Associates Inc.; L5178Y TK +/- Mouse Lymphoma Mutagenicity Assay, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone** was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538 (Ames Test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of the preliminary bacterial toxicity determinations, **methyl ethyl ketone,** diluted with DMSO, was tested for mutagenicity at concentrations up to 32 ul/plate (presence metabolic activation) and 16 ul/plate (absence metabolic activation) using the preincubation technique. **Methyl ethyl ketone** did not cause a reproducible positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Microbiological Associates, Inc.; Salmonella/Mammalian-Microsome Preincubation Mutagenicity Assay (Ames Test), (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone (**MEK) was evaluated in bacterial tester strains E. coli WP2 and WP2uvrA and Salmonella TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain JD1, both in the presence and absence of added metabolic

activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, MEK, diluted with DMSO, was tested for mutagenicity at concentrations up to 4000 ug/plate in the bacterial tests and 5000 ug/plate in the yeast tests using the agar overlay method. MEK did not cause a positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Shell Sittingbourne Research Centre; Toxicity Studies with Chemical Solvents: Short-Term in Vitro Tests for Genotoxic Activity with Methyl Ethyl Ketone. (1982), EPA Document No. 878210125, Fiche No. OTS0206206] **UNREVIEWED**

Methyl ethyl ketone was evaluated for the ability to increase the incidence of micronucleated polychromatic erythrocytes in bone marrow of male and female CD-1 mice treated by single i.p. injection (Micronucleus Test). Groups of 10 mice (5 male, 5 female) were sacrificed 12, 24 and 48 hours following injection of **methyl ethyl ketone** in corn oil at a dose of 1.96 ml/kg body weight (calculated LD20 dose). The ratio of normochromatic to polychromatic erythrocytes were not significantly different ($p > 0.05$, ANOVA) in the treated groups compared with vehicle controls, regardless of sacrifice time. The incidence of micronucleated polychromatic erythrocytes was increased above the vehicle control 24 hours after administration, but was not considered statistically significant when compared to all treatment and vehicle control groups regardless of sacrifice time ($p > 0.05$, ANOVA).
[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Micronucleus Cytogenetic Assay in Mice, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The effects of **methyl ethyl ketone** were examined in the rat hepatocyte primary culture/DNA repair assay. Based on preliminary toxicity tests, **methyl ethyl ketone** was tested at concentrations of 5.0 (relative toxicity 74.67%), 2.5, 1.0, 0.5, 0.1 or 0.01 ul/ml (relative toxicity 6.67%). None of the tested concentrations caused a significant increase in unscheduled DNA synthesis over the solvent control (DMSO).
[Microbiological Associates Inc.; Unscheduled DNA Synthesis in Rat Primary Hepatocytes, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The ability of **methyl ethyl ketone** to cause chromosome aberrations was evaluated in cultured rat (strain not reported) liver cell line. Based on preliminary toxicity determinations, rat liver cultures were exposed to 250, 500 or 1000 ug/ml and incubated for 24 hours. Two hours prior to the end of incubation, colcemid was added and at the end of incubation period 100 cells from each culture were analyzed. No increase (statistical analysis not reported) in the frequency of chromatid gaps, chromatid breaks or total chromatid aberrations were observed in any of the cultures.
[Sittingbourn Research Center; Toxicity Studies with Chemical Solvents: Short Term In Vitro Tests for Genotoxic Activity with Methyl Ethyl Ketone, (1982), EPA Document No. 878210125, Fiche No. OTS0206206] **UNREVIEWED**

Non-Human Toxicity Excerpts:

THE SINGLE DOSE ORAL TOXICITY ... HAS BEEN DETERMINED TO BE 3.3 G/KG ... FOR RATS. MASSIVE DOSES MAY BE EXPECTED TO RESULT IN IRRITATION OF THE LUNG & ... /CNS DEPRESSION/.

[Patty, F. (ed.). Industrial Hygiene and Toxicology: Volume II: Toxicology. 2nd ed. New York: Interscience Publishers, 1963. 1732]**PEER REVIEWED**

Guinea pigs exposed to 3300 ppm for 13.5 hr showed no signs of intoxication. Exposure to 10,000 ppm for a similar period produced irritation of the eyes and nose within 4 min and /CNS depression/ between 4-5 hr. Exposure to 33,000 ppm for 200 min produced /CNS depression/ and death. Exposure to 100,000 ppm for 45-55 min produced /CNS depression/ after 10 min.

[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1753]**PEER REVIEWED**

Exposure /of rats/ to 2000 ppm /for 2 hr/ showed no apparent toxicity. Exposure to 8000 ppm killed 3 of 6 rats in 8 hr, while 16,000 ppm for 1 hr caused death of all the animals.

[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1753]**PEER REVIEWED**

EXPOSURE TO 1500 PPM OF **METHYL ETHYL KETONE (**MEK) ALONE FOR 7-9 WK DID NOT CAUSE PARALYSIS BUT DID ELEVATE PLASMA CHOLINESTERASE LEVELS IN MICE, RATS, & CHICKENS.

[COURI D ET AL; PROC ANNU CONF ENVIRON TOXICOL, 5TH, AMRL-TR-74-125: 109 (1974)]**PEER REVIEWED**

ANALYSIS OF PORPHYRIN CONTENT OF MURINE ERYTHROLEUKEMIA (MEL) CELLS INCUBATED WITH 2-**BUTANONE** SHOWED THAT INCR HEMOGLOBIN SYNTH WAS ACCOMPANIED BY ACCUM OF PORPHYRINS.

[EBERT PS ET AL; CHEM BIOL INTERACT 36 (1): 61 (1981)]**PEER REVIEWED**

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissues consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed.

[Schmidt R; Respiration 46 (4): 62-9 (1984)]**PEER REVIEWED**

METHYL ETHYL KETONE DELAYED MATCH-TO-SAMPLE DISCRIMINATION TASK IN THE JUVENILE BABOON & ALSO SLOWED RESPONSE TIMES & INCR EXTRA RESPONSES.
[GELLER I; NEUROBEHAV TOXICOL 1 (SUPPL 1): 9 (1979)]**PEER REVIEWED**

METHYL ETHYL KETONE WAS EVALUATED FOR EFFECTS ON A DELAYED MATCH TO SAMPLE DISCRIMINATION TASK IN THE JUVENILE BABOONS. THE ANIMALS WERE EXPOSED TO HALF THE THRESHOLD LIMIT VALUE (245 MG/CU M) FOR 24 HR PER DAY DURING A 7 DAY PERIOD. EACH EXPOSURE CONDITION AFFECTED ACCURACY OF PERFORMANCE MINIMALLY BUT RESULTED IN INCREASED AND DECREASED EXTRA RESPONSES DURING THE DELAY INTERVALS.
[GELLER I; PHARMACOL BIOCHEM BEHAV 11 (4): 401-6 (1979)]**PEER REVIEWED**

Intraperitoneal injection of 750, 1500 or 2000 mg/kg **methyl ethyl ketone** to guinea pigs resulted in elevated serum ornithine carbamyl transferase (OCT) activity at the highest dose, where one of four animals died, and deposition of lipids in the liver with either 1500 or 2000 mg/kg was found.
[DiVincenzo GD et al; Am Ind Hyg Assoc J 34: 329 (1974)]**PEER REVIEWED**

Incubation of Ehrlich-Landschutz diploid ascites tumor cells in media containing 50 and 100 ppm **methyl ethyl ketone** resulted in the destruction of 10.5 and 14.0% of the cells. Control incubations lost only 4.2% of cells in the 5 hr period.
[Holmberg; Environ Res 7: 183 (1974)]**PEER REVIEWED**

Mutagenicity screening in Escherichia coli WP2, and Salmonella typhimurium strains TA1535, TA1537, TA1536 and TA1538 was negative.
[Smirasu Y; J Environ Poll Control 12: 407 (1976)]**PEER REVIEWED**

Pregnant rats inhaled 0, 400, 1000, or 3000 ppm of **methyl ethyl ketone** for 7 hr/day on days 6-15 of gestation. Maternal toxicity evidenced by decreased weight gain and increased water consumption was seen among rats exposed to 3000 ppm. Fetotoxicity (increased incidence of 2 minor skeletal variants) was observed among litters of rats exposed to 3000 ppm.
[Deacon MM et al; Toxicol Appl Pharmacol 59 (3): 620-2 (1981)]**PEER REVIEWED**

Groups of rats were exposed to 100 ppm hexane, 200 ppm **methyl ethyl ketone (**MEK), or fresh air in an exposure chamber 12 hr daily for 24 weeks. Body weight, motor nerve conduction velocity, distal motor latency, and mixed conduction velocities were measured before exposure and after 4, 8, 12, 16, 20, and 24 wk exposure. ... Exposure to 200 ppm MEK significantly increased motor nerve conduction velocity, and mixed conduction velocities and decreased distal motor latency after 4 week exposure; but at a later stage no significant changes were found. Mixed exposure to 100 ppm hexane and 200 ppm MEK significantly decreased distal motor latency after 4 week exposure and decreased motor nerve conduction velocity and mixed conduction velocities after 20 and 24 week exposure.
[Takeuchi Y et al; Br J Ind Med 40 (2): 199-203 (1983)]**PEER REVIEWED**

Groups of Sprague-Dawley rats were exposed, by inhalation to ... **methyl ethyl ketone (**800 ppm, 2345 mg/cu m) ... for 4 weeks. Increased liver weights and liver-to-body weight ratios were observed. **Methyl**

ethyl ketone depressed the formation of 2 metabolites of androstenedione but did not alter the concentration of cytochrome p450 in companion in vitro microsomal metabolism studies.
[Toftgard R et al; Scand J Work Environ Health 7 (1): 31-7 (1981)]**PEER REVIEWED**

Vapors in concn of 1000 ppm or 3000 ppm were embryotoxic and fetotoxic in rats causing acaudia, imperforate anus, and brachygnathia, as well as retardation of fetal development.
[Gosselin, R.E., R.P. Smith, H.C. Hodge. Clinical Toxicology of Commercial Products. 5th ed. Baltimore: Williams and Wilkins, 1984.,p. II-185]**PEER REVIEWED**

Testing of a drop on rabbit eyes indicates moderate reversible injury, graded 5 on a scale of 1-10. The compound was tested externally on the eyes of rabbits, and, according to the degree of injury observed after 24 hours, rated on a scale of 1 to 10. The most severely injurious substances have been rated 10.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 617]**PEER REVIEWED**

Male and female Fischer 344 rats were exposed to 0, 1250, 2500, or 5000 ppm **methyl ethyl ketone (**MEK) vapors 6 hr/day, 5 day/wk for 90 days. The 90 day exposures had no adverse effect on the clinical health or growth of male or female rats except for a depression of mean body wt in the 5000 ppm exposure group. The 5000 ppm animals had a slight but significant increase in liver weight, liver weight/body weight ratio, and liver weight/brain weight ratio at necropsy. Serum glutamic-pyruvic transaminase (SGPT) activity in the 2500 ppm female rats was elevated while the 5000 ppm female rats exhibited significantly decreased serum glutamic-pyruvic transaminase SGPT activity. In addition, alkaline phosphatase, potassium, and blood glucose values for the 5000 ppm female rats were increased. ...

Chinese hamsters were exposed to ... **methyl ethyl ketone ...** known to be a strong inducer of aneuploidy in the yeast Saccharomyces cerevisiae. ... Solvent yielded negative results in the micro-nucleus test.
[Basler A; Mutat Res 174 (1): 11-13 (1986)]**PEER REVIEWED**

... Cultures of mature organotypic cord ganglia were extracted from fetal mouse spinal cord with the attached dorsal root. MEK at 300 ug/ml nutrient fluid was added to cultures for periods of up to 7 weeks. Cultures were examined under microscope twice weekly for morphological changes and were sampled at 3, 5, and 7 weeks for electron microscopy. Treated cultures remained viable for the 7 week exposure period. After 6 to 7 weeks of exposure, distinct intraaxonal inclusion occurred along proximal and distal internodes of occasional sensory peripheral nerves (PNS). The structures lengthened and darkened throughout the exposure period and were often associated with axoplasmic granularity. The earliest change in cytoplasm was dispersion of Nissl bodies, which resulted in excessive numbers of free ribosomes or polyribosomal changes. There was a distension of neuronal cisternal systems. By week 5 there were abnormal amounts of smooth or agranular endoplasmic reticulum which appeared swollen with a translucent material. A swollen agranular recticulum was often associated with foci of axoplasmic debris. By week 7, intra-axonal cores of debris and myelin whorls were documented in 25% of the central nervous system and sensory perpipheral nerves axons examined ultrastucturally. ...

[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.96 (1993)]**PEER REVIEWED**

The developmental effects observed at an MEK vapor concentration of 3000 ppm were reexamined. Pregnant Sprague-Dawley rats were exposed to 400, 1000, or 3000 ppm of MEK for 7 hr/day on days 6 to 15 of gestation. There were no effects on maternal liver weight; however, a significant decrease in maternal body weight gain was observed in the animals exposed to 3000 ppm of MEK. In addition, none of the exposures affected the pregnancy rate, the number of implantations or fetal resorptions, the litter size, or the fetal body weight. Unlike the initial study, there were no gross or soft-tissue malformations at any exposure level; however, the 3000-ppm exposure caused a significant increase in the incidence of delayed skeletal ossifications (skull and neck) and an increase in the incidence of extra lumbar ribs. /It was/ concluded that MEK was not embryotoxic or teratogenic and only slightly fetotoxic in the rat at exposure concentrations of 3000 ppm.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1759]**PEER REVIEWED**

Groups of pregnant and nonpregnant mice were exposed to MEK vapor concentrations of 400, 1000, or 3000 ppm for 7 hr/day for 10 consecutive days (for pregnant mice, days 6 to 15 of gestation). The nonpregnant and pregnant mice showed no differences in sensitivity to the MEK exposures. The maternal body weight gain, extragestational weight gain, uterine weight, pregnancy rate, and implantation ratio were not affected by exposure to MEK vapors relative to control. The 3000-ppm exposure did, however, result in a relative increase in maternal liver and kidney weight. The percentage of live fetuses, resorptions, and dead fetuses per litter was also unaffected by the treatment. A concentration-related decrease in fetal weight was observed for both the male and females. Although there were no statistically significant increases in the number of malformed fetuses per litter, there were several atypical malformations (cleft palate, fused ribs, missing vertebrae, and syndactyly) not often found in control litters. A statistically significant increase in the incidence of misaligned sternebrae was observed in the fetuses exposed to 3000 ppm of MEK. No developmental or maternal effects were observed at vapor concentrations of 1000 ppm or less. After considering the results from the present study together with results obtained in rats, the authors concluded that MEK vapors caused mild developmental toxicity at concentrations that caused maternal toxicity.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1758]**PEER REVIEWED**

TSCA Test Submissions:

The ability of **methyl ethyl ketone** to induce morphological transformation in the BALB/3T3 mouse cell line (Cell Transformation Assay) was evaluated both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary clonal toxicity determinations (exposure time=2 hrs), **methyl ethyl ketone,** diluted with phosphate buffered saline, was tested at 18, 13 and 9ul/ml in the absence of metabolic activation, with cell survival ranging from 93.3% to 51.1% relative to the solvent control. Assays with metabolic activation were tested at 10, 8 and 6ul/ml (exposure time=2 hrs), with cell survival ranging from 85.7% to 67.3%. None of the tested concentrations produced significantly greater transformation frequencies ($p > 0.05$, Modified Poisson Distribution) relative to the solvent control.

[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Morphological Transformation Assay using BALB/3T3 Mouse Embryo Cells, Final Report, (1984), EPA Document No. 40-8444072, EPA Fiche No. OTS0507470] **UNREVIEWED**

An inhalation teratology study was conducted with pregnant Sprague-Dawley rats (25/group) receiving whole body exposure to **methyl ethyl ketone** in a dynamic air flow chamber, 7 hours/day on days 6 through 15 of gestation. There was no effect of treatment for all animals as indicated by clinical observations, absolute or relative liver weights, food consumption, number of pregnancies, and mortality. Maternal toxicity was evident by statistical differences between high dose groups and controls for: maternal body weights, maternal body weight gain and water consumption. The average number of live fetuses per litter, incidence of resorption rates, fetal body weight or crown-rump length were not significantly affected by treatment. Significant differences were observed between the fetuses of the control and high dose group for skeletal variations, but no significant external or soft-tissue alterations were observed in any of the fetuses of treated females.

[Dow Toxicology Research Laboratory; Teratologic Evaluation of Inhaled Methyl Ethyl Ketone in Rats, (1979), EPA Document No. 878210652, Fiche No. OTS0206178] **UNREVIEWED**

The ability of **methyl ethyl ketone** to induce specific locus mutations at the TK locus in cultured L5178Y mouse lymphoma cells (Mouse Lymphoma Mutagenicity Assay) was evaluated in the presence and absence of Aroclor-induced rat liver S9 metabolic activation. Based on preliminary toxicity tests, 10 nonactivated cultures treated with 12, 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2 and 0.89ul/ml were cloned, producing a range of 46 - 122% total growth. Ten S9-activated cultures treated with 8.9, 6.7, 5.0, 3.8, 2.8, 2.1, 1.6, 1.2, 0.89 and 0.67ul/ml were cloned, producing a range of 30 - 116% total growth. None of the cultures that were cloned produced mutant frequencies which were significantly greater than the mean mutant frequency of the solvent controls (DMSO, acetone).

[Microbiological Associates Inc.; L5178Y TK +/- Mouse Lymphoma Mutagenicity Assay, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone** was evaluated in Salmonella tester strains TA98, TA100,

TA1535, TA1537 and TA1538 (Ames Test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of the preliminary bacterial toxicity determinations, **methyl ethyl ketone,** diluted with DMSO, was tested for mutagenicity at concentrations up to 32 ul/plate (presence metabolic activation) and 16 ul/plate (absence metabolic activation) using the preincubation technique. **Methyl ethyl ketone** did not cause a reproducible positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Microbiological Associates, Inc.; Salmonella/Mammalian-Microsome Preincubation Mutagenicity Assay (Ames Test), (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The mutagenicity of **methyl ethyl ketone (**MEK) was evaluated in bacterial tester strains E. coli WP2 and WP2uvrA and Salmonella TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain JD1, both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, MEK, diluted with DMSO, was tested for mutagenicity at concentrations up to 4000 ug/plate in the bacterial tests and 5000 ug/plate in the yeast tests using the agar overlay method. MEK did not cause a positive response in any of the bacterial tester strains, either with or without metabolic activation.
[Shell Sittingbourne Research Centre; Toxicity Studies with Chemical Solvents: Short-Term in Vitro Tests for Genotoxic Activity with Methyl Ethyl Ketone. (1982), EPA Document No. 878210125, Fiche No. OTS0206206] **UNREVIEWED**

Methyl ethyl ketone was evaluated for the ability to increase the incidence of micronucleated polychromatic erythrocytes in bone marrow of male and female CD-1 mice treated by single i.p. injection (Micronucleus Test). Groups of 10 mice (5 male, 5 female) were sacrificed 12, 24 and 48 hours following injection of **methyl ethyl ketone** in corn oil at a dose of 1.96 ml/kg body weight (calculated LD20 dose). The ratio of normochromatic to polychromatic erythrocytes were not significantly different ($p > 0.05$, ANOVA) in the treated groups compared with vehicle controls, regardless of sacrifice time. The incidence of micronucleated polychromatic erythrocytes was increased above the vehicle control 24 hours after administration, but was not considered statistically significant when compared to all treatment and vehicle control groups regardless of sacrifice time ($p > 0.05$, ANOVA).
[Microbiological Associates Inc.; Activity of Methyl Ethyl Ketone in the Micronucleus Cytogenetic Assay in Mice, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The effects of **methyl ethyl ketone** were examined in the rat hepatocyte primary culture/DNA repair assay. Based on preliminary toxicity tests, **methyl ethyl ketone** was tested at concentrations of 5.0 (relative toxicity 74.67%), 2.5, 1.0, 0.5, 0.1 or 0.01 ul/ml (relative toxicity 6.67%). None of the tested concentrations caused a significant increase in unscheduled DNA synthesis over the solvent control (DMSO).
[Microbiological Associates Inc.; Unscheduled DNA Synthesis in Rat Primary Hepatocytes, Final Report, (1984), EPA Document No. 40-8444072, Fiche No. OTS0507470] **UNREVIEWED**

The ability of **methyl ethyl ketone** to cause chromosome aberrations was evaluated in cultured rat (strain not reported) liver cell line. Based on preliminary toxicity determinations, rat liver cultures were exposed

to 250, 500 or 1000 ug/ml and incubated for 24 hours. Two hours prior to the end of incubation, colcemid was added and at the end of incubation period 100 cells from each culture were analyzed. No increase (statistical analysis not reported) in the frequency of chromatid gaps, chromatid breaks or total chromatid aberrations were observed in any of the cultures.
[Sittingbourn Research Center; Toxicity Studies with Chemical Solvents: Short Term In Vitro Tests for Genotoxic Activity with Methyl Ethyl Ketone, (1982), EPA Document No. 878210125, Fiche No. OTS0206206] **UNREVIEWED**

Resting cells of Lactobacillus brevis 24 reduced **methyl ethyl ketone (**MEK) quantitatively to 2-butyl alcohol when incubated in phosphate buffer for 24 hr at 30 deg C.
[Keen AR et al; J Dairy Res 41: 249-57 (1974)]**PEER REVIEWED**

Rats were given a single oral dose of **methyl ethyl ketone (**MEK). The blood concn of MEK and metabolites 4 hr after dosing were: MEK (94.1 mg/100 ml); 2-butanol (3.2 mg/100 ml); 3-hydroxy-2-butanol (2.4 mg/100 ml) and 2,3-butanediol (8.6 mg/100 ml). Blood concn of the parent compound and metabolites 18 hr after dosing with MEK were: MEK (6.2 mg/100 ml); 2-butanol (0.6 mg/100 ml); 3-hydroxy-2-**butanone** (1.4 mg/100 ml); and 2,3-butanediol (25.6 mg/100 ml).
[Dietz FKJ, Traiger GJ; Toxicology 14: 209-14 (1979)]**PEER REVIEWED**

MEK has been reported to be a metabolic end product of natural gas (methane 88%, ethane 5%, propane 5%, iso-butane 2%, with traces of t-butyl mercaptan and methyl acrylate) inhaled for 2 hr by ICR mice ... In an in vivo study of the metabolism of propane, n-butane and iso-butane inhaled for 1 hr by ICR mice,

it was found that n-butane gave rise to sec-butanol and MEK ... In vitro studies showed that mouse liver microsomal preparations metabolized n-butane to sec-butanol, the precursor of MEK ... Inhalation by male Sprague-Dawley rats of sec-butanol at concn of 5900 mg/cu m (2000 ppm) for 3 days or 1475 mg/cu m (500 ppm) for 5 days caused marked enzyme induction of cytochrome P-450 in liver and kidney but other butanol isomers did not have this effect ... The authors concluded that the mechanism of induction was via the sec-butanol metabolite MEK.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

... the toxic effects of MEK and 2-butanol were essentially identical in rats, and that 2-butanol was rapidly oxidized to MEK. ... identified the metabolites of MEK in guinea pigs as 2-butanol, 3-hydroxy-2-**butanone** and 2,3-butanediol. They hypothesized that the metabolism followed both oxidative and reductive pathways, with the latter leading to the production of 2-butanol.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.52 (1993)]**PEER REVIEWED**

In rats exposed by inhalation to 1760 mg MEK/cu m (600 ppm), there were only marginal effects on microsomal cytochrome P-450 activities ... However, a daily dose of 1.4 mL MEK per kg for 3 days incr the amounts of ethanol- and phenobarbital-inducible cytochromes P-450 ...
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.53 (1993)]**PEER REVIEWED**

In a study on male Sprague-Dawley rats, pretreatment with MEK elevated total microsomal cytochrome P-450 and NADPH-dependent cytochrome-c-reductase, the rates of oxidation of N-nitrosodimethylamine, benzphetamine and pentoxyresorufin, and also the levels of immunoreactive protein for both P-450 isozymes ... In a study of hepatotoxicity in rats, ... found that MEK incr liver cytochrome P-450 content (33-86%) and glutathione-S-transferase (GST) activity (42-64%) but had no effect on serum glutamate dehydrogenase (GLDH) activity. ... studied the effects on hepatic cytochrome P-450 activities of repeated daily doses of 1.87 mL/kg given by gavage to male Fischer-344 rats. The activity of 7-ethoxy coumarin-O-deethylase was incr by up to 500% after 1 to 7 days of MEK treatment, but there was practically no change in benzphetamine-N-demethylase activity. In another study in male Sprague-Dawley rats, admin of MEK by gavage cause an incr in hepatic acetanilide hydroxylase and a marginal incr in aminopyrine-N-demethylase activities ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.53 (1993)]**PEER REVIEWED**

MEK has been identified as a minor but normal constituent of urine ... serum and urine of diabetics ... and expired air ... . Its production in the body has been attributed to isoleucine catabolism ... studies ... indicate that the same metabolites are produced and excreted in humans as in experimental animals. ... further indicated that in an inhalation exposure to 590 mg MEK/cu m (200 ppm) the calculated areas under the curves of blood solvent concn versus time (AUC) for MEK and 2,3-butanediol were equal, which suggests that MEK is almost completely transformed to 2,3-butanediol. The bulk of MEK absorbed thus enters the general metabolism and is transformed to simple compounds like carbon dioxide and water.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.55 (1993)]**PEER REVIEWED**

Absorption, Distribution & Excretion:

Measurable (2.54 to 13 ug/l) quantities of **methyl ethyl ketone** appeared in expired air of adult humans 3 min following dermal exposure to 100 ml **methyl ethyl ketone** applied to 91.5 sq cm of skin.
[Wurster; J Pharm Sci 54: 554 (1965)]**PEER REVIEWED**

Ketones are readily absorbed through the intact skin. Usually they are rapidly excreted ... in the expired air. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1170]**PEER REVIEWED**

Workers occupationally exposed to **methyl ethyl ketone (**MEK) were examined. ... Workers exposed to 300 micrograms per liter MEK, the aveolar concn was 30% of the environmental concn. Lung uptake averaged 1.05 mg/min. The blood concn of MEK ranged from 842 to 9573 ug/l, with a mean of 2630 ug/l. Blood concn of MEK were strongly correlated with alveolar concn. MEK was more soluble in heart and muscle tissue than in lung tissue or fat. Urinary MEK excretion ranged from 120 to 1120 mg/l, with a mean of 487 mg/l. ... MEK was not persistent in the tissues. ... Urinary excretion of MEK and acetylmethylcarbinol are only around 0.1% of MEK lung absorption, the main pathway through which MEK is eliminated is unknown.
[Perbellini L et al; Intern Arch Occup Environ Health 54 (1): 73-81 (1984)]**PEER REVIEWED**

ALTHOUGH ABSORPTION ... THROUGH THE SKIN MAY OCCUR, IT HAS BEEN SHOWN THAT IT IS LOW IN TOXICITY BY THIS ROUTE.
[Patty, F. (ed.). Industrial Hygiene and Toxicology: Volume II: Toxicology. 2nd ed. New York: Interscience Publishers, 1963. 1732]**PEER REVIEWED**

Percutaneous absorption of MEK appears to be rapid ... MEK was present in the exhaled air of human subjects within 2.5-3.0 min after it was applied to normal skin of the forearm, and the concn of MEK in exhaled air reached a plateau in 2-3 hr. The rate of absorption was controlled mainly by the moisture content of the skin. With dry skin, absorption was slow, and it took 4-5 hr for the concn of MEK in expired air to attain a plateau. With moist skin, absorption was very rapid initially. MEK was detected in expired air in measurable concn within 30 sec after an application of MEK to the forearm, and a max concn in expired air, averaging 4X the plateau level for normal and dry skin, was achieved in 10-15 min.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.49 (1993)]**PEER REVIEWED**

The absorption of MEK via the lungs was examined ... in a study of workers exposed in industrial workplace. The MEK concn in alveolar and expired air correlated significantly with the environmental concn, and averaged 30% of the latter. In more recent studies ... values for pulmonary absorption ranging from 41.1% to 55.8% were obtained. ... Deeper inhalation incr the alveolar volume relative to the dead space (the non-alveolar volume of the respiratory system), and thus incr the apparent absorption ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.49 (1993)]**PEER REVIEWED**

Results of studies ... indicated a rapid transfer of MEK vapor into the blood stream. ... the concn of MEK

in the blood and urine were significantly correlated with the environmental concn, indicating rapid transfer to the blood and thence to other tissues. In human volunteer subjects, exercise during exposure markedly incr the MEK level in blood in comparison with sedentary behavior ... indicating that the blood MEK level also depended on the rate of uptake. ... also found significant correlations between environmental levels of MEK and amounts excreted in the urine of exposed workers. The concn of MEK in urine rose from essentially 0 to 70% of its max value during the first 2 hr of an 8-hr shift ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.50 (1993)]**PEER REVIEWED**

... studied biological monitoring of occupational exposure to MEK in 67 healthy male workers employed in plastic bag or video-tape production. Their ages ranged between 18 and 52 yr with an average working experience of 8.6 yr. for the majority of the workers, atmospheric MEK concn were in the range of 30-885 mg/cu m (10-300 ppm). MEK concn in urine, blood and exhaled air were measured once/week at the end of a shift. About 10% of absorbed MEK was eliminated in the exhaled air. Following exposure to 590 mg/cu m (200 ppm), the urinary concn was 5.1 umol/L or 4.11 mg/g creatinine. The correlation coefficients between atmospheric MEK concn and end-of-shift urine, blood and exhaled air were 0.89, 0.85, and 0.79, respectively. The authors also reported good correlation between blood and urinary MEK ... and between blood and exhaled air concn ... but poor correlation between exhaled air and urinary MEK concn.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.50 (1993)]**PEER REVIEWED**

In male rats given a large MEK dose (1505 or 1690 mg/kg) in water, blood concn reached maxima of 0.95 and 0.94 mg/mL 4 hr after ingestion and subsequently declined sharply, indicating protracted absorption of this dose from the GI tract ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

... intraperitoneal injection of MEK in research on metabolism and toxicity, suggest that absorption from the peritoneal cavity is rapid.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

The distribution of MEK in human tissues was examined ... in two solvent-exposed workers who died suddenly of heart attacks at the workplace. The results of this study ... indicate that the solubility of MEK is similar for all tissues. ... With a blood/air partition coefficient of 202, MEK can reach equilibrium concn in a compartment in about 3 min. Distribution volumes were 6.0 for vessel-rich tissues, 39.6 for muscle and 12.8 for fat. Biological half-lives for the same tissues were 0.8, 21.8 and 23.3 min, respectively.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

The results of in vitro measurements at 37 deg C of human tissue-gas partition coefficients, obtained by exposing samples of blood and tissue to a known concn of MEK ... The partition coefficients ranged from 96 to 162, but did not exceed 111, with the exception of whole blood (125), blood plasma (133) and fat (162). Other blood-gas partition coefficients measurements for MEK are 202 ... and 215 ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51

(1993)]**PEER REVIEWED**

... provided evidence that MEK can enter the liver of rats and guinea-pigs, and ... reported that it can cross the placenta and enter the human fetus.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

MEK and its metabolites are excreted by the lungs and kidneys. ... only 3% of the calculated absorbed dose during a 4-hr exposure to 590 mg MEK/cu m (200 ppm) was secreted unchanged in the exhaled air of volunteers after the exposure. The fractional elimination of unchanged substance however depends on the efficiency of metabolic clearance. Since metabolic saturation for MEK in humans begins at relatively low levels (about 100 ppm) of exposure ... proportionally greater amounts of MEK would be expected to be excreted via the lungs (and kidneys) at high exposure levels.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.55 (1993)]**PEER REVIEWED**

Relatively little of absorbed MEK is excreted unchanged via the kidneys; a study of occupationally exposed workers revealed that it is less than 0.1% of the alveolar uptake ... In a similar study of workers occupationally exposed to a mixture of solvents, the excretion of MEK and a major recognizable metabolite, 3-hydroxy-2-**butanone**, was 0.1% of alveolar uptake ... The concentrations of both MEK and 3-hydroxy-2-**butanone** in urine were significantly correlated with the environmental level of MEK. Other metabolites of MEK, 2-butanol or 2,3-butanediol ... identified in the serum of guinea pigs, were not detected in the urine of the exposed workers. ... however ... human excretion of 2,3-butanediol was individually variable but averaged 2% of the absorbed MEK. The urinary excretion of 2-butanol, a minor metabolite of MEK was examined ... clearance of 2-butanol admin by gavage in rabbits was about 14% of the admin dose and in the form of a glucuronide.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.55 (1993)]**PEER REVIEWED**

Absorption of methylethylketone is rapid via inhalation and ingestion, and the compound is presumably a moderate skin penetrant as well. Since methylethylketone is both water and lipid soluble, it is rather evenly distributed in tissues.
[Zenz, C., O.B. Dickerson, E.P. Horvath. Occupational Medicine. 3rd ed. St. Louis, MO., 1994 149]**PEER REVIEWED**

Biological Half-Life:

Guinea pigs were given a single dose of **methyl ethyl ketone (**MEK) ip at 450 mg/kg. Blood samples were taken via cardiac puncture at 1, 2, 4, 6, 8, 12 and 16 hr after dosing. Serum half-life of MEK was estimated at 270 minutes.
[Divincenzo GD et al; Toxicol Appl Pharm 36: 511-22 (1976)]**PEER REVIEWED**

... The biological half lives for elimination of acetone and MEK calculated on the basis of a first order kinetic assumption were 3.9 hours and 49 minutes, respectively. ... Workers exposed to acetone or MEK for 6 to 8 hours could expect to have a residual body burden of acetone the next morning, whereas MEK would be essentially eliminated.
[Brown WD et al; The Changing Nature of Work and Workforce,

Proceedings of the Third Joint US-Finish Science Symposium p.111-14 (1986)]**PEER REVIEWED**

The distribution of MEK in human tissues was examined ... in two solvent-exposed workers who died suddenly of heart attacks at the workplace. ... Distribution volumes were 6.0 for vessel-rich tissues, 39.6 for muscle and 12.8 for fat. Biological half-lives for the same tissues were 0.8, 21.8 and 23.3 min, respectively.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

Both animal and human data indicate a rapid turnover of MEK. In guinea-pigs receiving an ip dose of 450 mg MEK/kg, the half-life of MEK in blood serum was 4.5 hr and the clearance time for MEK in serum was 12 hr. For the metabolites 2-butanol, 3-hydroxy-2-**butanone** and 2,3-butanediol, the clearance time in serum was 11 hr ... In a study ... on rats given an oral dose of 2-**butanone** of 2.1 mg/kg, there was a half-life of 3.6 hr for MEK in blood if the rate of loss was assumed to be constant between the two times of measurement (4 and 18 hrs) after dosing. Data from a study ... on rats receiving oral doses of 2-butanol or MEK also indicate a half-life of about 4 hr for MEK. ... the clearance rate for 3-hydroxy-2-**butanone** and 2,3-butanediol was independent of dose for the two doses used (0.4 and 0.8 g/kg) and that the half-lives for these metabolites of MEK were 47 min and 3.45 hr, respectively.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.56 (1993)]**PEER REVIEWED**

... reported a steady incr in blood concn during 4-hr exposures of human volunteer subjects to 590 mg/cu m (200 ppm) and observed a rapid elimination of MEK, with half-lives of 30 min during the first post-exposure hr and 81 min thereafter. An inhalation study with two volunteer subjects exposed to MEK for 4 hr at concn of 74,590 and 1,180 mg/cu m (25,200 and 400 ppm, respectively) indicated that the kinetics of MEK were dose dependent at higher exposure concn, i.e., much higher levels of MEK in blood were reached relative to inhaled concn, and the post-exposure elimination of MEK in blood was slower (zero-order kinetics). Simulated exposure to MEK for 8 hr suggests that saturation kinetics are reached at about 295 mg/cu m (100 ppm) at rest and 148 mg/cu m (50 ppm) during light exercise ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.56 (1993)]**PEER REVIEWED**

Mechanism of Action:

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissue consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed. An enzyme associated metabolic damage with a concomitant impairment of axonal flow is discussed as a possible underlying pathomechanism.
[Schmidt R et al; Respiration 46 (4): 362-9 (1984)]**PEER REVIEWED**

There is very limited info on the mechanisms of toxic action of MEK. Relatively high inhaled concn 1,475-29,500 mg/cu m (500-10,000 ppm) caused pulmonary vasoconstriction and hypertension in cats and dogs ... From the toxicological point of view, interactions leading to the potentiation of effects,

particularly neurotoxicity, by other intrinsically toxic substances constitute the main hazard of MEK. The mechanisms underlying these interactions are incompletely known ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.57 (1993)]**PEER REVIEWED**

Interactions:

IT DOES NOT APPEAR TO BE NEUROTOXIC BY ITSELF, IT POTENTIATES NEUROTOXICITY OF OTHER HEXACARBONS; REPORTED IN HUMANS EXPOSED TO **METHYL ETHYL KETONE (**MEK) & N-HEXANE.
[ALTENKIRCH ET AL; J NEUROL 214: 152 (1977)]**PEER REVIEWED**

Methyl ethyl ketone potentiates carbon tetrachloride hepatoxicity in rats. Oral dosing with **methyl ethyl ketone** at 1.87, 2.4, or 1.2 ml/kg followed by ip injection with carbon tetrachloride at 0.1 ml/kg significantly enhanced the hepatotoxicity of carbon tetrachloride as measured by increased serum glutamic pyruvic transaminase activity and hepatic triglyceride concentration and decreased hepatic glucose-6-phosphatase activity.
[Traiger GJ, Bruckner JV; J Pharmacol Exp Ther 196: 493 (1976)]**PEER REVIEWED**

A study of the potential relationship between **methyl ethyl ketone** and 2,5-hexanedione was conducted. Male F344 rats weighing between 200 and 320 g were used. A sensorimotor/behavioral battery consisting of two simple reflex tests, hind limb grasp and hind limb place, and two complex function tests, balance beam and accelerating rotorod performance, was used for identification and quantification of neurological deficits. ... The enhancement of 2,5-hexanedione induced toxicity by **methyl ethyl ketone** could be correlated with higher tissue exposures of 2,5-hexanedione in animals receiving the combined treatment. ... **Methyl ethyl ketone** may compete with 2,5-hexanedione for critical and non-critical binding sites at the target neurofilament proteins.
[Ralston WH et al; Toxicol Appl Pharm 81 (2): 319-27 (1985)]**PEER REVIEWED**

The effects of acute exposure to toluene and **methyl ethyl ketone (**MEK) singly and in combination were investigated. ... The effects of these chemicals on behavior and body burden were determined. ... MEK had no effect on any measures. Behavior performance was not affected by the combination of toluene and MEK. Body burden of the two solvents was not additive. ... Neither chemical potentiated the effect of the other at the concentrations studied.
[Dick RB et al; Int Arch Occup Environ Health 54 (2): 91-109 (1984)]**PEER REVIEWED**

... An important observation was the marked potentiation of peripheral neurotoxicity observed when animals were exposed to n-butyl ketone in combination with **methyl ethyl ketone** at a ratio of 1:5, n-butyl ketone: **methyl ethyl ketone.** The latter solvent showed no neurotoxic effect alone.
[Saida K et al; J Neuropathol Exp Neurol 35 (3): 207-25 (1976)]**PEER REVIEWED**

... The toxic neuropathy induced by **methyl ethyl ketone** is clinically and morphologically identical with that induced by n-hexane and methyl butyl ketone. **Methyl ethyl ketone** can act synergistically with n-hexane to produce toxic neuropathy.

[Alterkirch H et al; J Neurology 214: 137-52 (1977)]**PEER REVIEWED**

Ingestion of ethanol (0.8 g/kg) combined with an inhalation exposure to MEK (590 mg/cu m, 200 ppm) inhibited the oxidative metabolism of MEK and led to a marked incr in the blood concn of MEK ... There was a concurrent, even more pronounced elevation of the blood 2-butanol concn; the most likely explanation is competitive inhibition by ethanol of the oxidation of 2-butanol back to MEK. Ethanol also appeared to interact with the further biotransformation of 2,3-butanediol as the urinary excretion of the metabolite was incr. Co-exposure with xylene, however, had no effect on the human metabolism or rate of elimination of MEK ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.57 (1993)]**PEER REVIEWED**

... found that MEK and certain other polar aprotic solvents were strong inducers of aneuploidy in the yeast. The induction of aneuploidy by MEK was markedly potentiated by coexposure to ethyl acetate ... or with nocodazol ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.80 (1993)]**PEER REVIEWED**

MEK interacts with hexacarbon compounds and potentiates their neurotoxicity ... Potentially MEK co-exposure could affect the metabolism of the hexacarbon compounds or the toxic process by which the hexacarbons induce the neuropathy. ... The metabolic pathway involves hepatic microsomal oxidation to 2,5-hexanedione, the proximate neurotoxicant, which is thought to induce cross-linking of neurofilaments, blockage of transport at the node of Ranvier, and swelling from accumulated neurofilaments proximal to the nodes and axonal degeneration distal to the nodes.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.101 (1993)]**PEER REVIEWED**

Carbon tetrachloride (CCl4), chloroform (CHCl3) and related haloalkane solvents are liver and kidney poisons as well as central nervous depressants ... It has long been known that the hepatotoxic action of CCl4 is potentiated by ethanol, and more recently that the hepatic and/or renal toxicity of CCl4, CHCl3, trichloroethylene, 1,1,2-trichloroethane and related compounds is potentiated by n-hexane, ethanol, isopropanol, acetone, MEK, MBK, 2,5-HD, and other ketones or chemicals that are metabolized to ketones ... Even an incr of naturally occurring ketones in the body via diabetes can precipitate potentiation. Decr the transformation of isopropanol to acetone by the admin of an inhibitor of alcohol dehydrogenase, pyrazole, has reduced potentiation of haloalkane toxicity. Although the phenomenon is referred to as haloalkane toxicity, experimental work in general appears largely or entirely limited to chlorinated compounds, and specific studies on MEK are limited to interactions with CCl4 and CHCl3.

Absorption, Distribution & Excretion:

Measurable (2.54 to 13 ug/l) quantities of **methyl ethyl ketone** appeared in expired air of adult humans 3 min following dermal exposure to 100 ml **methyl ethyl ketone** applied to 91.5 sq cm of skin.
[Wurster; J Pharm Sci 54: 554 (1965)]**PEER REVIEWED**

Ketones are readily absorbed through the intact skin. Usually they are rapidly excreted ... in the expired air. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1170]**PEER REVIEWED**

Workers occupationally exposed to **methyl ethyl ketone (**MEK) were examined. ... Workers exposed to 300 micrograms per liter MEK, the aveolar concn was 30% of the environmental concn. Lung uptake averaged 1.05 mg/min. The blood concn of MEK ranged from 842 to 9573 ug/l, with a mean of 2630 ug/l. Blood concn of MEK were strongly correlated with alveolar concn. MEK was more soluble in heart and muscle tissue than in lung tissue or fat. Urinary MEK excretion ranged from 120 to 1120 mg/l, with a mean of 487 mg/l. ... MEK was not persistent in the tissues. ... Urinary excretion of MEK and acetylmethylcarbinol are only around 0.1% of MEK lung absorption, the main pathway through which MEK is eliminated is unknown.
[Perbellini L et al; Intern Arch Occup Environ Health 54 (1): 73-81 (1984)]**PEER REVIEWED**

ALTHOUGH ABSORPTION ... THROUGH THE SKIN MAY OCCUR, IT HAS BEEN SHOWN THAT IT IS LOW IN TOXICITY BY THIS ROUTE.
[Patty, F. (ed.). Industrial Hygiene and Toxicology: Volume II: Toxicology. 2nd ed. New York: Interscience Publishers, 1963. 1732]**PEER REVIEWED**

Percutaneous absorption of MEK appears to be rapid ... MEK was present in the exhaled air of human subjects within 2.5-3.0 min after it was applied to normal skin of the forearm, and the concn of MEK in exhaled air reached a plateau in 2-3 hr. The rate of absorption was controlled mainly by the moisture content of the skin. With dry skin, absorption was slow, and it took 4-5 hr for the concn of MEK in expired air to attain a plateau. With moist skin, absorption was very rapid initially. MEK was detected in expired air in measurable concn within 30 sec after an application of MEK to the forearm, and a max concn in expired air, averaging 4X the plateau level for normal and dry skin, was achieved in 10-15 min.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.49 (1993)]**PEER REVIEWED**

The absorption of MEK via the lungs was examined ... in a study of workers exposed in industrial workplace. The MEK concn in alveolar and expired air correlated significantly with the environmental concn, and averaged 30% of the latter. In more recent studies ... values for pulmonary absorption ranging from 41.1% to 55.8% were obtained. ... Deeper inhalation incr the alveolar volume relative to the dead space (the non-alveolar volume of the respiratory system), and thus incr the apparent absorption ... .

[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.49 (1993)]**PEER REVIEWED**

Results of studies ... indicated a rapid transfer of MEK vapor into the blood stream. ... the concn of MEK in the blood and urine were significantly correlated with the environmental concn, indicating rapid transfer to the blood and thence to other tissues. In human volunteer subjects, exercise during exposure markedly incr the MEK level in blood in comparison with sedentary behavior ... indicating that the blood MEK level also depended on the rate of uptake. ... also found significant correlations between environmental levels of MEK and amounts excreted in the urine of exposed workers. The concn of MEK in urine rose from essentially 0 to 70% of its max value during the first 2 hr of an 8-hr shift ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.50 (1993)]**PEER REVIEWED**

... studied biological monitoring of occupational exposure to MEK in 67 healthy male workers employed in plastic bag or video-tape production. Their ages ranged between 18 and 52 yr with an average working experience of 8.6 yr. for the majority of the workers, atmospheric MEK concn were in the range of 30-885 mg/cu m (10-300 ppm). MEK concn in urine, blood and exhaled air were measured once/week at the end of a shift. About 10% of absorbed MEK was eliminated in the exhaled air. Following exposure to 590 mg/cu m (200 ppm), the urinary concn was 5.1 umol/L or 4.11 mg/g creatinine. The correlation coefficients between atmospheric MEK concn and end-of-shift urine, blood and exhaled air were 0.89, 0.85, and 0.79, respectively. The authors also reported good correlation between blood and urinary MEK ... and between blood and exhaled air concn ... but poor correlation between exhaled air and urinary MEK concn.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.50 (1993)]**PEER REVIEWED**

In male rats given a large MEK dose (1505 or 1690 mg/kg) in water, blood concn reached maxima of 0.95 and 0.94 mg/mL 4 hr after ingestion and subsequently declined sharply, indicating protracted absorption of this dose from the GI tract ... .
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

... intraperitoneal injection of MEK in research on metabolism and toxicity, suggest that absorption from the peritoneal cavity is rapid.
[WHO; Environ Health Criteria 143: Methyl Ethyl Ketone p.51 (1993)]**PEER REVIEWED**

The distribution of MEK in human tissues was examined ... in two solvent-exposed workers who died suddenly of heart attacks at the workplace. The results of this study ... indicate that the solubility of MEK is similar for all tissues. ... With a blood/air partition coefficient of 202, MEK can reach equilibrium concn in a compartment in about 3 min. Distribution volumes were 6.0 for vessel-rich tissues, 39.6 for muscle and 12.8 for fat. Biological half-lives for the same tissues were 0.8, 21.8 and 23.3 min, respectively.

Mechanism of Action:

The effects of the solvents n-hexane, **butanone** (**methyl ethyl ketone,** MEK) and a mixture of both in the intrapulmonary nerve system of rats were studied by light and electron microscopy. The alteration in the fine structures of the tissue consisted in a disseminated swelling of axons due to a striking multiplication of neurofilaments. Nonspecific axonal alterations could be demonstrated as well. The latter consisted in clusters of phospholipid material within the axoplasm of nerve fibers and the cytoplasm of Schwann cells plus an accumulation of glycogen granules in the axoplasm. Additionally, single degenerative changes of Schwann cells were observed. An enzyme associated metabolic damage with a concomitant impairment of axonal flow is discussed as a possible underlying pathomechanism.
[Schmidt R et al; Respiration 46 (4): 362-9 (1984)]**PEER REVIEWED**

There is very limited info on the mechanisms of toxic action of MEK. Relatively high inhaled concn 1,475-29,500 mg/cu m (500-10,000 ppm) caused pulmonary vasoconstriction and hypertension in cats and dogs ... From the toxicological point of view, interactions leading to the potentiation of effects, particularly neurotoxicity, by other intrinsically toxic substances constitute the main hazard of MEK. The mechanisms underlying these interactions are incompletely known ... .

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Methyl ethyl ketone's production and use as a solvent for coatings, resins, rubbers, plastics, pharmaceuticals, adhesives and rubber cements will result in its release to the environment through various waste streams. Its use as a starting material or intermediate in the manufacture of chemical products will also lead to its release to the environment. **Methyl ethyl ketone** occurs naturally as a metabolic byproduct of plants and animals and is released into the atmosphere by volcanoes and forest fires. Based on an experimental vapor pressure of 91 mm Hg at 25 deg C, **methyl ethyl ketone** is expected to exist solely as a vapor in the ambient atmosphere. Vapor-phase **methyl ethyl ketone** is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals with an estimated atmospheric half-life of about 14 days. This compound is also expected to undergo photolysis in the atmosphere by natural sunlight. Photochemical degradation of **methyl ethyl ketone** by natural sunlight is expected to occur at approximately 1/5 the rate of degradation by photochemically produced hydroxy radicals. **Methyl ethyl ketone** is expected to have very high mobility in soils based upon measured Koc values of 29 and 34 obtained in silt loams. Volatilization from dry soil surfaces is expected based upon the vapor pressure of this compound. Volatilization from moist soil surfaces is also expected based upon the measured Henry's Law constant of 4.7X10-5 atm-cu m/mol. The volatilization half-life of **methyl ethyl ketone** from silt and sandy loams was measured as 4.9 days. This compound is expected to biodegrade under aerobic and anaerobic conditions. In water, **methyl ethyl ketone** is not expected to adsorb to suspended solids or sediment based upon its measured Koc values. Volatilization from water surfaces is expected to be an important environmental fate process given its Henry's Law constant. Estimated half-lives for a model river and model lake are 19 and 197 hours, respectively. Bioconcentration in aquatic organisms is considered low based upon an estimated BCF value of 1. Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used. The general population may be exposed to **methyl ethyl ketone** through the use of commercially available products containing this compound such as paints, adhesives, and rubber cements. Exposure will also arise from inhalation of ambient air and ingestion of drinking water and food that contains **methyl ethyl ketone. (**SRC)

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,221,857 workers (201,308 of these are female) are potentially exposed to **methyl ethyl ketone** in the US(1). Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used(SRC). The 8 hour TWA exposure to **methyl ethyl ketone** was 45.4 ppm in a survey of 50 occupationally exposed male subjects working in a magnetic videotape producing factory(2). These workers had average concns of **methyl ethyl ketone** of 2 ppm and 1.4 mg/l in breath and blood samples respectively(2). The mean concn of **methyl ethyl ketone** in the breathing zones of 47 US plants using polyurethane coatings was 4.33 ppm(3). **Methyl ethyl ketone** was detected in the breathing zones in 20 of 70 samples (mean concn 12 mg/cu m) obtained from autobody shops and spray paint shops in Australia(4).

[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982)]**PEER REVIEWED**

The kinetics of inhaled **methyl ethyl ketone (**MEK) in human volunteers was studied in an exposure chamber. Relative pulmonary uptake was about 53% throughout a 4 hr exposure period at 200 ppm. Blood MEK concentration rose steadily until the end of exposure. Repeated bicycle exercise increased the overall blood MEK level markedly in comparison to sedentary activity, with transient peaks in association with cycling; thus blood MEK concentration depended both on the rate of uptake and the amount taken up. Only 3% of the absorbed dose was excreted unchanged by exhalation. A well known metabolite of MEK, 2,3-butanediol, was detected in the urine with maximum rates of excretion at about 6 to 12 hr from the beginning of exposure. About 2% of the MEK dose taken up by the lungs was excreted in the urine as 2,3-butanediol. ... Elimination of MEK in blood appeared to exhibit two phases: the initial alpha-phase (T1/2= 30 min; kel alpha= 0.023) over the first post-exposure hour, followed by the terminal beta-phase (T1/2= 81 min; kel beta= 0.009).
[Liira J et al; Int Arch Occup Environ Health 60 (3): 195-200 (1988)]**PEER REVIEWED**

Worker exposures were investigated in April 1983 at the Hoover Company, North Canton, Ohio. ... Area and personal air samples for numerous contaminants were collected and nonionizing radiation levels were measured. ... General medical questionnaires and blood tests for **methyl ethyl ketone (**MEK) were given to exposed workers. ... No respiratory symptoms or pulmonary function disorders were identified in the foundry workers, and MEK was detected in the blood of only one worker at 1.4 ug/ml. ...

Atmospheric Concentrations:

The presence of solvents such as toluene, xylene, **methyl ethyl ketone,** and other similar products in the indoor air of an automobile body repair shop, an offset printing facility and the adjacent dwellings was monitored, and the individual exposure of the corresponding workers and residents was tested by biological monitoring of exhaled breath and by personal air sampling. The concentrations of solvents tested in the air of both sites surveyed were lower than prevailing Dutch Maximum Allowable Concentration levels. The levels of solvents recorded in the air of apartments situated on top of the facilities surveyed were significantly higher than the levels recorded in the surrounding dwellings. The levels of **methyl ethyl ketone,** toluene and xylene in personal air samples of employees at the body shop

were 1.5 times higher than in ambient air. The level of toluene in alveolar air of residents living above the automobile repair shop was 50 percent higher than that recorded in spot samples. The levels of other solvents were equal to or lower than the detection level. At the offset printing facility, toluene, xylene, butylacetate, 2-ethoxyethanol and cyclohexanone in air and in personal air samples followed the same general pattern identified for the body shop. In a dwelling next to the shop and in an apartment on top of the shop, the concentrations ranged from 3 to 9 percent and 14 to 19 percent, respectively, of the levels recorded inside the facility itself.

Environmental Fate/Exposure Summary:

Methyl ethyl ketone's production and use as a solvent for coatings, resins, rubbers, plastics, pharmaceuticals, adhesives and rubber cements will result in its release to the environment through various waste streams. Its use as a starting material or intermediate in the manufacture of chemical products will also lead to its release to the environment. **Methyl ethyl ketone** occurs naturally as a metabolic byproduct of plants and animals and is released into the atmosphere by volcanoes and forest fires. Based on an experimental vapor pressure of 91 mm Hg at 25 deg C, **methyl ethyl ketone** is expected to exist solely as a vapor in the ambient atmosphere. Vapor-phase **methyl ethyl ketone** is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals with an estimated atmospheric half-life of about 14 days. This compound is also expected to undergo photolysis in the atmosphere by natural sunlight. Photochemical degradation of **methyl ethyl ketone** by natural sunlight is expected to occur at approximately 1/5 the rate of degradation by photochemically produced hydroxy radicals. **Methyl ethyl ketone** is expected to have very high mobility in soils based upon measured Koc values of 29 and 34 obtained in silt loams. Volatilization from dry soil surfaces is expected based upon the vapor pressure of this compound. Volatilization from moist soil surfaces is also expected based upon the measured Henry's Law constant of 4.7X10-5 atm-cu m/mol. The volatilization half-life of **methyl ethyl ketone** from silt and sandy loams was measured as 4.9 days. This compound is expected to biodegrade under aerobic and anaerobic conditions. In water, **methyl ethyl ketone** is not expected to adsorb to suspended solids or sediment based upon its measured Koc values. Volatilization from water surfaces is expected to be an important environmental fate process given its Henry's Law constant. Estimated half-lives for a model river and model lake are 19 and 197 hours, respectively. Bioconcentration in aquatic organisms is considered low based upon an estimated BCF value of 1. Occupational exposure may be through inhalation and dermal contact with this compound at workplaces where **methyl ethyl ketone** is produced or used. The general population may be exposed to **methyl ethyl ketone** through the use of commercially available products containing this compound such as paints, adhesives, and rubber cements. Exposure will also arise from inhalation of ambient air and ingestion of drinking water and food that contains **methyl ethyl ketone. (**SRC)

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **methyl ethyl ketone** with photochemically-produced hydroxyl radicals has been measured as 1.15X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 14 days at an atmospheric concn of 5.0X10+5 hydroxyl radicals per cu cm(1,SRC). **Methyl ethyl ketone** is also expected to undergo photodecomposition in the atmosphere by natural sunlight(2,3). Based on the actinic fluxes within the planet boundary layer, along with an estimated quantum yield and absorption cross section, the rate of photodissociation of **methyl ethyl ketone** by natural sunlight is approximately 1/5 the rate of dissociation by hydroxyl radicals(3). This compound is not expected to undergo hydrolysis in the environment due to a lack of functional groups which hydrolyze(SRC).

Volatilization from Water/Soil:

The Henry's Law constant for **methyl ethyl ketone** was measured as 4.7X10-5 atm-cu m/mole(SRC) at 25 deg C(1). This value indicates that **methyl ethyl ketone** will volatilize from water surfaces(2,SRC). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec) is estimated as approximately 19 hours(2,SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec) is estimated as approximately 197 hours(2,SRC). **Methyl ethyl ketone** is expected to volatilize from dry soil surfaces given its experimental vapor pressure of 91 mm Hg at 25 deg C(3,SRC). The volatilization half-life of **methyl ethyl ketone** from silt and sandy loams was measured as 4.9 days(4).

METHYL ETHYL KETONE

CASRN: 78-93-3

For other data, click on the Table of Contents

Atmospheric Concentrations:

The presence of solvents such as toluene, xylene, **methyl ethyl ketone,** and other similar products in the indoor air of an automobile body repair shop, an offset printing facility and the adjacent dwellings was monitored, and the individual exposure of the corresponding workers and residents was tested by biological monitoring of exhaled breath and by personal air sampling. The concentrations of solvents tested in the air of both sites surveyed were lower than prevailing Dutch Maximum Allowable Concentration levels. The levels of solvents recorded in the air of apartments situated on top of the facilities surveyed were significantly higher than the levels recorded in the surrounding dwellings. The levels of **methyl ethyl ketone,** toluene and xylene in personal air samples of employees at the body shop were 1.5 times higher than in ambient air. The level of toluene in alveolar air of residents living above the automobile repair shop was 50 percent higher than that recorded in spot samples. The levels of other solvents were equal to or lower than the detection level. At the offset printing facility, toluene, xylene, butylacetate, 2-ethoxyethanol and cyclohexanone in air and in personal air samples followed the same general pattern identified for the body shop. In a dwelling next to the shop and in an apartment on top of the shop, the concentrations ranged from 3 to 9 percent and 14 to 19 percent, respectively, of the levels recorded inside the facility itself.
[Verhoeff AP et al; Int Arch Occup Environ Health 59 (2): 153-63 (1987)]**PEER REVIEWED**

URBAN/SUBURBAN: **Methyl ethyl ketone** was detected at a mean concn of 1.5 ppb in Boston, MA(1). **Methyl ethyl ketone** was detected at mean concns of 1.35 ppb in Boston, MA, and 5.1 ppb in Houston, TX(2). The average concn of **methyl ethyl ketone** at 25 urban locations in the US was 1.4 ug/cu m(3). **Methyl ethyl ketone** was detected at a mean concn of 1.67 ppb in Los Angeles, CA(4) and in the Caldecott Tunnel in San Francisco, CA at a concn of 1.67 mg/l(5). **Methyl ethyl ketone** was detected at average concns of 0.222-1.366 ppb in Grenoble, France(6). An average concn of 0.638 ppb of **methyl ethyl ketone** was obtained from 714 atmospheric samples in the US(7).

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Methyl ethyl ketone** is produced, as an intermediate or final product, by process units covered under this subpart.

[40 CFR 60.489 (7/1/87)]**PEER REVIEWED**

Listed as a hazardous air pollutant (HAP) generally known or suspected to cause serious health problems. The Clean Air Act, as amended in 1990, directs EPA to set standards requiring major sources to sharply reduce routine emissions of toxic pollutants. EPA is required to establish and phase in specific performance based standards for all air emission sources that emit one or more of the listed pollutants. **Methyl ethyl ketone** is included on this list.

[Clean Air Act as amended in 1990, Sect. 112 (b) (1) Public Law 101-549 Nov. 15, 1990]**QC REVIEWED**

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: HIGHLY FLAMMABLE: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Health: Inhalation or contact with material may irritate or burn skin and eyes. Fire may produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control may cause pollution.

Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, ISOLATE for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Fire: CAUTION: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.

Preventive Measures:

Work practices and industrial hygiene techniques should minimize the volatilization of ketones in the workroom air in order to ensure that the exposure limits are not exceeded. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1173]**PEER REVIEWED**

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without hazard. Use water spray to disperse vapors and dilute standing pools of liquid.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Evacuation: If material leaking (not on fire) consider evacuation from downwind area based on amount of material spilled, location and weather conditions.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Personnel protection: Avoid breathing vapors. Keep upwind. ... Do not handle broken packages without protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **methyl ethyl ketone/. ...** Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents are highly flammable.
[Hart C; J Environ Health 49 (5): 282-6 (1987)]**PEER REVIEWED**

SRP: Local exhaust ventilation should be applied wherever there is an incidence of point source emissions or dispersion of regulated contaminants in the work area. Ventilation control of the contaminant as close to its point of generation is both the most economical and safest method to minimize personnel exposure to airborne contaminants.
PEER REVIEWED

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

SRP: Contaminated protective clothing should be segregated in such a manner so that there is no direct personal contact by personnel who handle, dispose, or clean the clothing. Quality assurance to ascertain the completeness of the cleaning procedures should be implemented before the decontaminated protective clothing is returned for reuse by the workers.
PEER REVIEWED

The worker should immediately wash the skin when it becomes contaminated.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

Work clothing that becomes wet should be immediately removed due to its flammability hazard.

Cleanup Methods:

The Hazardous Materials Technical Center (HMTC), an EPA emergency response cleanup services contractor cleaned up a **methyl ethyl ketone (**MEK) spill and decontaminated the groundwater. The spill cleanup involved removing low concentrations of MEK from groundwater. The spill was caused by an overturned tank truck containing 7200 gallons of MEK. MEK was directed into four dry wells that served as primary storm drainage. Immediately after the incident, 6000 gallons of water were pumped from the dry well; 2400 gallons of MEK were recovered from the water. About 1500 gallons of MEK were removed from the truck, and the remaining 3300 gallons of MEK either vaporized or entered an unsaturated zone. MEK concentrations up to 2200 mg/l were reduced to 50 ug/l before reinjection. Levels of MEK in the sample wells, production wells, and reinjection wells were reduced to nondetectable levels.

DOT Emergency Guidelines:

Fire or explosion: HIGHLY FLAMMABLE: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, ISOLATE for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Fire: CAUTION: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-127]**PEER REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Preventive Measures:

Work practices and industrial hygiene techniques should minimize the volatilization of ketones in the workroom air in order to ensure that the exposure limits are not exceeded. /Ketones/
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 1173]**PEER REVIEWED**

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without hazard. Use water spray to disperse vapors and dilute standing pools of liquid.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Evacuation: If material leaking (not on fire) consider evacuation from downwind area based on amount of material spilled, location and weather conditions.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

Personnel protection: Avoid breathing vapors. Keep upwind. ... Do not handle broken packages without protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 704]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **methyl ethyl ketone/. ...** Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents are highly flammable.
[Hart C; J Environ Health 49 (5): 282-6 (1987)]**PEER REVIEWED**

SRP: Local exhaust ventilation should be applied wherever there is an incidence of point source emissions or dispersion of regulated contaminants in the work area. Ventilation control of the contaminant as close to its point of generation is both the most economical and safest method to minimize personnel exposure to airborne contaminants.
PEER REVIEWED

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing

Office, 1997. 36]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

SRP: Contaminated protective clothing should be segregated in such a manner so that there is no direct personal contact by personnel who handle, dispose, or clean the clothing. Quality assurance to ascertain the completeness of the cleaning procedures should be implemented before the decontaminated protective clothing is returned for reuse by the workers.
PEER REVIEWED

The worker should immediately wash the skin when it becomes contaminated.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

Work clothing that becomes wet should be immediately removed due to its flammability hazard.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 36]**QC REVIEWED**

Cleanup Methods:

The Hazardous Materials Technical Center (HMTC), an EPA emergency response cleanup services contractor cleaned up a **methyl ethyl ketone (**MEK) spill and decontaminated the groundwater. The spill cleanup involved removing low concentrations of MEK from groundwater. The spill was caused by an overturned tank truck containing 7200 gallons of MEK. MEK was directed into four dry wells that served as primary storm drainage. Immediately after the incident, 6000 gallons of water were pumped from the dry well; 2400 gallons of MEK were recovered from the water. About 1500 gallons of MEK were removed from the truck, and the remaining 3300 gallons of MEK either vaporized or entered an unsaturated zone. MEK concentrations up to 2200 mg/l were reduced to 50 ug/l before reinjection. Levels of MEK in the sample wells, production wells, and reinjection wells were reduced to nondetectable levels.

EPA Method 1624 - Volatile Organic Compounds By GC/MS: Grab samples in municipal and industrial discharges are collected. If residual chlorine is present, add sodium thiosulfate. Extraction is performed by a purge and trap apparatus. An isotope dilution gas chromatography/mass spectrometry method for the determination of volatile organic compounds in municipal and industrial discharges is described. Unlabeled **methyl ethyl ketone** has a minimum level of 50 ug/l and a mean retention time of 848 sec.
[40 CFR 136 (7/1/88)]**PEER REVIEWED**

EPA Method 8015: Nonhalogenated Volatile Organics. For the analysis of solid waste, a representative sample (solid or liquid) is collected in a standard 40 ml glass screw-cap VOA vial equipped with a Teflon-faced silicone septum. Sample agitation, as well as contamination of the collected sample with air, must be avoided. Two VOA vials are filled per sample location, then placed in separate plastic bags for shipment and storage. Samples can be analyzed by direct injection or purge-and trap gas chromatography. A temperature program is used in the gas chromatograph to separate the organic compounds. Column 1 is an 8 ft by 0.1 in ID stainless steel or glass column packed with 1% SP-1000 on Carbopack-B 60/80 mesh or equivalent. Column 2 is a 6 ft by 0.1 in ID stainless steel or glass column packed with n-octane on Porasil-C 100/120 mesh (Durapak) or equivalent. Detection is achieved by a flame ionization detector (FID). Under the prescribed conditions, **methyl ethyl ketone** can be detected using this method. No statistical analysis was determined; specific method performance information will be provided as it becomes available.

The analytes were isolated from urine by solid-phase extraction and analyzed by capillary gas chromatography. The recovery rates were 50-70% for the 2,3-butanediol isomers and 88-96% for the other analytes. The precision of the method ranged 5-12% (standard deviation %). The detection limit was 1.0 and 1.4 mg/l for meso- and d,l 2,3-butanediol, respectively, and ranged 0.1-0.15 mg/l for the other analytes.

GLASS TUBE PACKED WITH ACTIVATED CHARCOAL IS USED TO TAKE AN INTEGRATED SAMPLE. GAS CHROMATOGRAPH EQUIPPED WITH A FLAME IONIZATION DETECTOR.
[WHITE LD ET AL; AM IND HYG ASSOC J 31 (2): 225 (1970)]**PEER REVIEWED**

ANALYTE: **METHYL ETHYL KETONE;** MATRIX: AIR; RANGE: 0.01 MG/SAMPLE; PROCEDURE: ADSORPTION ON CHARCOAL DESORPTION WITH CARBON DISULFIDE, GC; PRECISION: NOT GIVEN.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. V1 2500-2]**PEER REVIEWED**

EPA Method 1624 - Volatile Organic Compounds By GC/MS: Grab samples in municipal and industrial discharges are collected. If residual chlorine is present, add sodium thiosulfate. Extraction is performed by a purge and trap apparatus. An isotope dilution gas chromatography/mass spectrometry method for the determination of volatile organic compounds in municipal and industrial discharges is described. Unlabeled **methyl ethyl ketone** has a minimum level of 50 ug/l and a mean retention time of 848 sec.
[40 CFR 136 (7/1/88)]**PEER REVIEWED**

EPA Method 8015: Nonhalogenated Volatile Organics. For the analysis of solid waste, a representative sample (solid or liquid) is collected in a standard 40 ml glass screw-cap VOA vial equipped with a Teflon-faced silicone septum. Sample agitation, as well as contamination of the collected sample with air, must be avoided. Two VOA vials are filled per sample location, then placed in separate plastic bags for shipment and storage. Samples can be analyzed by direct injection or purge-and trap gas chromatography. A temperature program is used in the gas chromatograph to separate the organic compounds. Column 1 is an 8 ft by 0.1 in ID stainless steel or glass column packed with 1% SP-1000 on Carbopack-B 60/80 mesh or equivalent. Column 2 is a 6 ft by 0.1 in ID stainless steel or glass column packed with n-octane on Porasil-C 100/120 mesh (Durapak) or equivalent. Detection is achieved by a flame ionization detector (FID). Under the prescribed conditions, **methyl ethyl ketone** can be detected using this method. No statistical analysis was determined; specific method performance information will be provided as it becomes available.

Calibrate each personal sampling pump with sampler in line. Break the ends and attach sampler to personal sampling pump with flexible tubing. Sample at flow rate between 0.01 and 0.2 l/min for total sample size of 1.0 to 12 l.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. V1 2500-1]**PEER REVIEWED**

Activated charcoal, Ambersorb XE-348, and Amberlites XAD-2, XAD-4, and XAD-7 were evaluated as solid adsorbents for work-room air sampling of acetone, **methyl ethyl ketone,** methyl isobutyl ketone, methyl n-butyl ketone, cyclohexanone and isophorone. Activated charcoal had good capacity for the compounds investigated, but most ketones decomposed on this adsorbent during storage. Ambersorb XE-348 also showed good capacity for most of the ketones and decomposition was insignificant.

TOLUENE DIISOCYANATE

CASRN: 26471-62-5

For other data, click on the Table of Contents

Best Sections

Non-Human Toxicity Excerpts :

The effect of exposure to **toluene** diisocyanate vapor on pulmonary performance was studied in guinea pigs. Female English smooth haired guinea pigs were exposed to 1.4 ppm **toluene** diisocyanate vapor or air for 3 hours per day for 4 days, or to 0.02 ppm **toluene** diisocyanate for 6 hours per day for 70 days. Pulmonary performance was evaluated by the ventilatory response of the animals to 10% carbon dioxide. Serum antibodies to **toluene** diisocyanate were measured on days 22 and 50 and **toluene** diisocyanate pulmonary hypersensitivity was measured on days 37 and 38. Lung tissue histopathology was evaluated in all animals on day 50 following **toluene** diisocyanate exposure. Pulmonary response to 10% carbon dioxide diminished by 30 to 50% following **toluene** diisocyanate exposures at 1.4 ppm up to day 14. The ventilatory response showed recovery during the next 5 weeks. In contrast, animals exposed to 0.02 ppm **toluene** diisocyanate daily for 70 days showed no change in ventilatory response, nor did control animals that were not exposed to **toluene** diisocyanate. Antibodies were detected on day 22 and pulmonary hyprsensitivity to **toluene** diisocyanate was found in all animals exposed to 1.4 ppm **toluene** diisocyanate. No antibodies to **toluene** diisocyanate nor pulmonary hypersensitivity were detected in animals exposed to 0.02 ppm **toluene** diisocyanate or in control animals. Lung tissue on day 50 in the 1.4 ppm **toluene** diisocyanate exposed animals showed multifocal subchronic interstitial inflammation, localized pleural thickening, and peripheral lymphoid hyperplasia. No apparent abnormalities were observed in lung tissue of the 0.02 ppm exposed group. Exposure to 1.4 or 0.02 ppm **toluene** diisocyanate resulted in measurable and no apparent pulmonary toxicity in guinea pigs, respectively. The 10 percent carbon dioxide challenge provide several advantages for measuring pulmonary function.
[Wang KL et al; J Toxicol Environ Health 15 (1): 137-48 (1985)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Exposing guinea pigs to **toluene** diisocyanate causes an acute increase in airway responsiveness to inhaled acetylcholine. The mechanism of this increase in airway responsiveness is unknown. Capsaicin-sensitive afferent nerves and the tachykinins they release upon activation are important in controlling bronchomotor tone in guinea pigs. To determine whether tachykinins are important in **toluene** diisocyanate induced airway hyperresponsiveness, the effects of tachykinin depletion were studied using capsaicin, and competitive tachykinin antagonism, using (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P, on **toluene** diisocyanate induced airway hyperresponsiveness. In 9 of 9 untreated animals, **toluene** diisocyanate exposure caused a large and significant increase in airway responsiveness to acetylcholine. The mean concentration of acetylcholine required to decrease specific airway conductance by 50% below baseline (the PD50) was 1.51% before **toluene** diisocyanate exposure and 0.17% after **toluene** diisocyanate exposure ($p < 0.0005$). Capsaicin treatment had no effect on the PD50 but prevented the **toluene** diisocyanate induced increase in airway responsiveness in 10 of 12 animals. (The PD50 was 1.03% before **toluene** diisocyanate and 1.27% after **toluene** diisocyanate exposure.) Treatment with the tachykinin antagonist (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P also abolished the **toluene** diisocyanate induced increase in airway responsiveness in all 5 animals treated. Although **toluene** diisocyanate exposure also caused airway edema, the effect of capsaicin treatment on **toluene** diisocyanate induced hyperresponsiveness did not result from prevention of airway edema. **Toluene** diisocyanate exposure caused a marked increase in tracheal extravasation of intravenously administered Evans blue dye that was not prevented by capsaicin

Human Toxicity Excerpts :

The presence of different thresholds on bronchial reactivity to **toluene** diisocyanate was tested in 20 spray painters employed in the furniture industry and affected by TDI induced asthma. Bronchial provocation tests failed to demonstrate nonspecific hyperreactivity to methacholine. Exposure of the workers to **toluene** diisocyanate in concentrations ranging from 0.02 to 0.25 ppm demonstrated the occurrence of low, moderate and high thresholds of airways response to **toluene** diisocyanate in nine, seven and four patients, respectively. There was no association between the **toluene** diisocyanate response threshold and the positive response pattern to the lower range of **toluene** diisocyanate levels, but six of the nine patients with low threshold of response to **toluene** diisocyanate and six of the 11 patients with moderate or high thresholds had nonspecific bronchial hyperreactivity. The response to **toluene** diisocyanate also was not associated with the duration of the asthmatic condition, smoking, cessation of work or nonspecific response to methacholine. The pattern of response was not dose dependent in ten of 13 patients who had two positive bronchial provocation tests with different levels of **toluene** diisocyanate, although dual responses were recorded in three patients who had late reactions at low concentrations of **toluene** diisocyanate. The value of forced expiratory volume in one second, recorded during immediate reactions, showed a dose response relationship, in that it declined by 28.4% at lower **toluene** diisocyanate levels as compared to 38.3% following inhalation of higher doses of the compound; no such association was established for the late reaction to **toluene** diisocyanate. The results conclude that patients who are sensitive to **toluene** diisocyanate may have different thresholds of response to the agent.
[Paggiaro PL et al; Respiration 50 (3): 167-73 (1986)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Groups of 50 F344/N rats of each sex and 50 B6C3F1 mice of each sex were gavaged with corn oil or a mixture of **toluene** diisocyanate in corn oil for 5 days per wk for 105 or 106 wk. Female rats and mice were given doses of 60 or 120 mg/kg body weight, while male rats received 30 or 60 mg/kg, and male mice received 120 or 240 mg/kg. The **toluene** diisocyanate reacted with the moisture in the corn oil vehicle resulting in doses that were 10% to 23% below the target dose concn. The chemical product used was commercial grade **toluene** diisocyanate, which was an 80%-20% mixture of the 2,4- and 2,6-isomers. Chemical disposition and metabolism studies were conducted with each of the radiolabelled **toluene** diisocyanate isomers in male rats. Absorption of both of the **toluene** diisocyanate isomers occurred, with the highest concn found in the stomach, cecum, large intestine, and bladder. Excretion occurred via the feces and urine. The major metabolic products from the metabolism of 2,4-**toluene** diisocyanate were shown to be identical with those from the metabolism of the carcinogen, 2,4-diaminotoluene, whereas the metabolism of the 2,6-**toluene** diisocyanate isomer yielded one major product, identified as 2,6-bis(acetylamino)**toluene**. Greater than 10% depression in body weight gain occurred in all dosed groups of rats throughout most of the study. The major non-neoplastic lesions that were observed in both sexes of the **toluene** diisocyanate exposed rats were dose related incr in acute broncho-pneumonia, characterized as chemical pneumonitis, with incidences as high as 50%. In mice mean body weight gain was depressed in dosed male and in high dose females. The principle non-neoplastic lesion in mice that was attributed to chemical treatment was cytomegaly of the kidney tubular epithelium in males. Survival in all groups of dosed rats was significantly lower than in controls. A dose-dependent pattern of mortality did not commence until 70 wk of exposure, demonstrating that **toluene** diisocyanate elicited a cumulative toxic response. There was also significantly lower survival in high dose male, but not female mice, by comparison to controls. Despite the reduction of power and sensitivity in the rat studies caused by early mortality, statistically significant incr in tumor incidences were observed in many different target organs. **Toluene** diisocyanate was carcinogenic in F344/N rats, causing sc fibromas and fibrosarcomas in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland tumors in females.

(1990)]**PEER REVIEWED**

Metabolism/Metabolites :

It has been previously shown that tachykinin depletion or antagonism prevented the increase in airway responsiveness to inhaled acetylcholine caused by exposure to **toluene** diisocyanate in awake guinea pigs. To insure that the effects of tachykinins were not limited to the extrathoracic airways and were not dependent on effects of **toluene** diisocyanate on baseline airway caliber, airway responsiveness to acetylcholine inhaled through tracheostomy in anesthetized and ventilated guinea pigs that were exposed to **toluene** diisocyanate or air after treatment with the tachykinin antagonist spantide, the tachykinin metabolism inhibitor phosphoramidon, or the vehicles for each drug were determined. When these drugs were administered before and during **toluene** diisocyanate exposure, spantide significantly inhibited the **toluene** diisocyanate induced increase in acetylcholine responsiveness and phosphoramidon significantly potentiated this effect, whereas neither drug altered acetylcholine responsiveness in air exposed animals. To determine whether tachykinins were exerting their effect primarily during **toluene** diisocyanate exposure or during the subsequent acetylcholine challenge, the effect of each drug on acetylcholine responsiveness was also examined when the drugs were given after **toluene** diisocyanate exposure. At that time, spantide did not inhibit **toluene** diisocyanate induced acetylcholine hyperresponsiveness and phosphoramidon did not potentiate it. Neither drug nor **toluene** diisocyanate increased pulmonary resistance measured through a tracheostomy in these anesthetized and ventilated animals. These results suggest that the **toluene** diisocyanate induced increase in acetylcholine responsiveness is mediated by release of tachykinins into the intrathoracic airways during exposure to **toluene** diisocyanate.
[Sheppard D, Scypinski L; Am Rev Respir Dis 138 (3): 547-51 (1988)]**PEER REVIEWED**

Mechanism of Action :

The effects of **toluene** diisocyanate on T-cell subpopulations and circulating lymphocytes in ten persons (five males)): 19 to 50 yr old, with **toluene** diisocyanate induced occupational asthma were examined. Five subjects revealed early and late asthmatic reactions to **toluene** diisocyanate (dual responders) and five revealed late asthmatic reactions (late responders). Subjects underwent inhalation challenge with 0.005 to 0.015 ppm **toluene** diisocyanate or filtered air for 10 to 30 min on two occasions. One second forced expiratory volumes were measured before and at periodic intervals between 30 min and 24 hr after challenge. Venous blood samples were drawn 30 min and 8, 24, 48, and 72 hr after **toluene** diisocyanate. Total and differential leukocyte counts and T-cell subpopulations were determined. The five dual responders demonstrated forced expiratory volume in 1 sec decreased indicative of early and late asthmatic reactions and the five late responders demonstrated forced expiratory volume in 1 second decr indicative of a late asthmatic reaction. **Toluene** diisocyanate challenge did not affect the number of circulating erythrocytes and leukocytes. The percentage of eosinophils was significantly increased 24 hr after challenge and sustained for up to 48 hr. The percentages of neutrophils, lymphocytes, and monocytes were not altered by **toluene** diisocyanate. Among the T-lymphocyte subpopulation, the proportion of CD8(+) lymphocytes was significantly increased 8 hr after **toluene** diisocyanate challenge. The increase was more pronounced in the lat responders. An additional increase in CD8(+) lymphocytes occurred 48 hr post exposure in seven subjects but was unrelated to responder type. The number of CD4(+) cells did not change. This resulted in a decrease in the CD4(+)/CD8(+) ratio 8 and 48 hr after **toluene** diisocyanate challenge. It was concluded that **toluene** diisocyanate induced late asthmatic reactions are associated with an increase in the number of suppressor/cytotoxic lymphocytes and eosinophils in peripheral blood.

process (and that microvessels are abundant just beneath the epithelium). At days 6 and 21 after exposure to **toluene** diisocyanate PAS-positive cells were increased, but no other histological alterations were found. Also, the occurrence of peptide containing nerve fibres was not altered by **toluene** diisocyanate. After **toluene** diisocyanate exposure the airway smooth muscle tone was elevated as examined in vitro at base-line and at conc response to carbachol. The largest incr in tone were recorded 21 days after exposure to **toluene** diisocyanate. The abnormally large tone was not associated with an increased thickness of the smooth muscle layer nor was it associated with reduced effects of either beta 2-agonist (terbutaline) or xanthine (theophylline) relaxants. It is concluded that **toluene** diisocyanate induced plasma exudation into guinea pig airways for 17 hr without disrupting the epithelial lining and without causing major changes in the airway peptidergic innervation. Both the airway tone, and the number of mucous cells, are increased for at least 3 wk after exposure to **toluene** diisocyanate.

Mechanism of Action :

Serum neutrophil chemotactic activity, which is associated with mast cell or basophil activation, was quantitated to determine if mast cell or basophil mediators are released during bronchoprovocation-inhalation challenge with subirritant levels of **toluene** diisocyanate. Four subjects with suspected **toluene** diisocyanate induced asthma and four mite-sensitive subjects with asthma who served as a comparison group were studied. neutrophil chemotactic activity was measured in a multiwell, microchemotaxis chamber. Blood samples were collected, and forced expiratory volume in 1 second measurements were performed before challenge and at regular intervals during the subsequent 24 hr. Three of four workers clinically sensitive to **toluene** diisocyanate reacted to a subirritant **toluene** diisocyanate exposure. There was no increase in neutrophil chemotactic activity during placebo challenges. neutrophil chemotactic activity increased in the three **toluene** diisocyanate sensitive workers during early and late asthmatic reactions in quantities proportional to the forced expiratory volume in 1 second decline. No increase in neutrophil chemotactic activity was found during **toluene** diisocyanate exposures in the **toluene** diisocyanate negative worker. Gel filtration analysis demonstrated the main neutrophil chemotactic activity fraction eluted with macromolecules of an estimated molecular weight greater than 440,000 daltons. This characteristic is compatible with neutrophil chemotactic factor of basophil or mast cell origin. The kinetics of neutrophil chemotactic activity release were similar in mite- and **toluene** diisocyanate induced asthmatic reactions. A high correlation (r = 0.97; p = 0.0006) was obtained between the percent decrease in forced expiratory volume in 1 second during early asthmatic reactions and percent increase in neutrophil chemotactic activity. These observations support the hypothesis that activation of mast cells or basophils is associated with **toluene** diisocyanate induced early and late asthmatic reaction.
[Sastre J et al; J Allergy Clin Immunol 85 (3): 567-72 (1990)]**PEER REVIEWED**

Human Toxicity Excerpts :

Two men were exposed to **toluene** diisocyanate atmospheres at three different air concn (ca 25, 50 and 70 ug/cu m). The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8-cu m stainless-steel test chamber. The effective exposure period was 4 hr. The isomeric composition of the air in the test chamber was 30% 2,4-**toluene** diisocyanate and 70% 2,6-**toluene** diisocyanate. The concn of **toluene** diisocyanate in air of the test chamber was determined by an HPLC method using the 9-(N-methyl-amino-methyl)-anthracene reagent and by a continuous-monitoring filter-tape instrument. Following the hydrolysis of plasma and urine, the related amines, 2,4-toluenediamine and 2,6-toluenediamine, were determined as pentafluoropropionic anhydride derivatives by capillary gas chromatography using selected ion monitoring in the electron impact mode. In plasma, 2,4- and 2,6-toluenediamine showed a rapid-phase elimination half-time of ca 2-5 hr, and that for the slow phase was greater than 6 days. A connection was observed between concn of 2,4- and 2,6-**toluene** diisocyanate in air and the levels of 2,4- and 2,6-toluenediamine in plasma. The cumulated amount of 2,4-toluenediamine excreted in the urine over 24 hr was ca 15%-19% of the estimated inhaled dose of 2,4-**toluene** diisocyanate, and that of 2,6-toluenediamine was ca 17%-23% of the inhaled dose of 2,6-**toluene**

Human Toxicity Excerpts :

The mechanism by which late asthmatic reactions are induced by **toluene** diisocyanate, a low molecular weight chemical that causes occupational asthma in exposed subjects, is unknown. An investigation was conducted to determine whether early and late asthmatic reactions induced by **toluene** diisocyanate are associated with changes in airway responsiveness to methacholine and airway inflammation as determined by bronchoalveolar lavage. Forced expiratory volume in 1 second was measured before and at regular intervals after exposure to **toluene** diisocyanate and dose-response curves to methacholine and bronchoalveolar lavage at 8 hr after **toluene** diisocyanate /were performed/ in a group of 6 subjects with late asthmatic reactions and in 6 subjects with only early asthmatic reactions. The same procedure was followed 2 hr after **toluene** diisocyanate in a group of 6 subjects with previously documented late asthmatic reactions and in a group of 6 subjects without any previously documented asthmatic reaction after **toluene** diisocyanate. In subjects with late asthmatic reactions, neutrophils were increased at both 2 hr and 8 hr and eosinophils and airway responsiveness were increased only at 8 hr. By contrast, neutrophils, eosinophils and airway responsiveness were not increased at 8 hr after **toluene** diisocyanate in subjectswith an early asthmatic reaction or at 2 hr after **toluene** diisocyanate in normal control subjects. These results suggest that late asthmatic reactions to **toluene** diisocyanate, and the associated increase in airway responsiveness may be caused by airway inflammation.
[Fabbri LM et al; Am Rev Respir Dis 136 (1): 36-42 (1987)]**PEER REVIEWED**

Human Toxicity Excerpts :

Six workers with occupational asthma due to **toluene** diisocyanate were studied. For each worker a detailed clinical and occupational history was taken, and lung function measurement and skin intradermal tests for common allergens were carried out. Methacholine inhalation challenge was performed before **toluene** diisocyanate inhalation, and 8 hr after **toluene** diisocyanate inhalation. Methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, but went into the asthmatic range after **toluene** diisocyanate inhalation. These cases provid evidence that asthma can be induced by **toluene** diisocyanate in the absence of airway hyperresponsiveness. They further demonstrate that an isolated negative methacholine inhalation test cannot be used to exclude sensitization to **toluene** diisocyanate. Screening and follow-up studies on workers exposed on **toluene** diisocyanate require serial measurements of airway responsiveness and of variable air-flow obstruction.
[Mapp CE et al; Eur J Respir Dis 68 (2): 89-95 (1986)]**PEER REVIEWED**

Human Toxicity Excerpts :

Forty-three workers exposed to low levels of **toluene** diisocyanate during the process of producing polyurethane forms were examined immunologically for immunoglobulin-G, A, M, and E and serum enzyme activities such as serum angiotensin converting enzyme, serum lysozyme and glycylproline dipeptidyl aminopeptidase. Air concn of **toluene** diisocyanate was annually measured in various places of work during the past five years from 1979 to 1983. The results obtained in the present study were as follows. The air concn of **toluene** diisocyanate at all places of work was below the permissible concn level of 0.02 ppm throughout the study period. Subjective symptoms and abnormal findings on chest X-ray considered directly related to **toluene** diisocyanate exposure were no observed. No remarkable abnormal findings in blood cell counts and in serum biochemical studies could be seen in any of the workers. The serum immunoglobulin-G levels in workers directly exposed to **toluene** diisocyanate were significantly higher ($p < 0.05$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers. In the study of serum enzymatic activity, serum lysozyme activity in workers exposed directly to **toluene** diisocyanate was significantly higher ($p < 0.01$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers.

Metabolism/Metabolites :

Five men were exposed to **toluene** diisocyanate atmospheres for 7.5 hr. The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8 cu m stainless steel test chamber. The mean air concn of **toluene** diisocyanate was ca 40 ug/cu m, which corresponds to the TLV of Sweden. The inhaled doses of 2,4- and 2,6-**toluene** diisocyanate were ca 120 ug. **Toluene** diisocyanate in the test chamber air was determined by an HPLC method using the 9-(N-methylaminomethyl)-anthracene reagent and by a continuous monitoring filter-tape instrument. After hydrolysis of plasma and urine, the related amines, 2,4- and 2,6-toluenediamine 2,4-, and 2,6-TDA), were determined as pentafluoropropionic anhydride derivatives by capillary gas-chromatography using selected ion monitoring in the electron-impact mode. The urinary elimination of the toluenediamines showed a possible biphasic pattern, with rapid first phases for 2,4-toluenediamine (mean half-life for the concn in urine, 1.9 hr) and for 2,6-toluenediamine (mean half-life for the concn in urine, 1.6 hr). The cumulative amount of 2,4-toluenediamine excreted in urine within 28 hr ranged from 8% to 14% of the estimated dose of 2,4-**toluene** diisocyanate, and the cumulative amount of 2,6-toluenediamine in urine ranged from 14% to 18% of the 2,6-**toluene** diisocyanate dose. The average urinary level of 2,4-toluenediamine was 5 ug/l in the 6 to 8 hr sample (range 2.8-9.6 ug/l), and the corresponding value fo 2,6-toluenediamine was 8.6 ug/l (range, 5.6-16.6 ug/l). Biological monitoring of exposure to 2,4- and 2,6-**toluene** diisocyanate by analysis of 2,4- and 2,6-toluenediamine in urine is feasible.
[Skarping G et al; Int Arch Occup Environ Health 63 (2): 83-8 (1991)]**PEER REVIEWED**

Human Toxicity Excerpts :

To determine whether late asthmatic reactions and the associated increase in airway induced by **toluene** diisocyanate are linked to airway inflammation, inhibition by prednisone was investigated. Ten "sensitized" subjects were studied in 2 sets of experiments. In the first set, each subject was given no treatment and was studied before and for 8 hr after exposure to **toluene** diisocyanate. In the second set, 2 to 4 wk later, each subject was studied before treatment and then during treatment with prednisone (50 mg once a day for 3 days, orally), both before and after exposure to **toluene** diisocyanate. To assess late asthmatic reactions to **toluene** diisocyanate FEV1 /was measured/ immediately before and after exposure, then hourly for 8 hr. To assess changes in airway responsiveness, a /measurement was made of/ the provocation dose (mg) of methacholine causing a 20% decrease in FEV1 (PD20FEV1) before and 8 hr after exposure to **toluene** diisocyanate. When the subjects received no prednisione treatment, **toluene** diisocyanate caused late asthmatic reactions and increased airway responsiveness. By contrast, when the subjects received prednisone, **toluene** diisocyanate caused no late asthmatic reaction or increased airway responsiveness. Prednisone did not change baseline airway caliber or airway responsiveness. These results suggest that late asthmatic reactions and the associated increase in airway responsiveness induced by **toluene** diisocyanate in "sensitized" subjects may depend on the development of a steroid-responsive acute inflammatory reaction within the airways.
[Fabbri LM; Am Rev Respir Dis 132 (5): 1010-4 (1985)]**PEER REVIEWED**

Human Toxicity Excerpts :

A worker developed **toluene** diisocyanate induced asthma in 1974. On reassessment, 11 yr after leaving the chemical plant where **toluene** diisocyanate was produced, he had no respiratory symptoms and normal bronchial reactivity in response to methacholine, and showed no reaction when challenged with a subirritant concn of **toluene** diisocyanate. He developed asthma within five months of returning to the workplace. Repeat challenge testing showed bronchial hyperreactivity to methacholine and to the specific sensitising agent, **toluene** diisocyanate. This clinical pattern could be due to underlying **toluene** diisocyanate sensitivity with resolution and reappearance of hyperresponsiveness to methacholine and **toluene** diisocyanate reactivity associated with workplace **toluene** diisocyanate exposure. Alternatively, this worker may have developed sensitisation to **toluene** diisocyanate anew.

Mechanism of Action :

Leukotriene B4 release from the lungs of sensitized subjects during asthmatic reactions induced by **toluene** diisocyanate was investigated. Three groups of **toluene** diisocyanate sensitized subjects were examined, one after no exposure to **toluene** diisocyanate, the second 8 hr after an exposure to **toluene** diisocyanate that caused an early asthmatic reaction, and the third 8 hr after an exposure to **toluene** diisocyanate that caused a late asthmatic reaction. Bronchoalveolar lavage fluid was analysed by reverse-phase HPLC and by specific radioimmunoassay. The mean concn of leukotriene B4 was higher (0.31 + or - 0.09 (standard error) ng/ml, range 0.15-0.51) in bronchoalveolar lavage fluid of sensitized subjects who developed a late asthmatic reaction than in bronchoalveolar lavage fluid of subjects who developed an early asthmatic reaction (0.05 + or - 0.04 ng/ml, range 0-0.224), and no leukotriene B4 was detectable in the control subjects. Bronchoalveolar lavage was also performed 8 hr after **toluene** diisocyanate exposure on four **toluene** diisocyanate sensitized late-dual reactors who were on steroid treatment. In this group of subjects no leukotriene B4 was detectable. These results suggest that leukotriene B4 may be involved in late asthmatic reactions induced by **toluene** diisocyanate.

Interactions :

The effects of methacholine inhalation on airway responsiveness in **toluene** diisocyanate induced asthma were studied in six workers with a history of sensitivity to **toluene** diisocyanate. Symptoms among subjects included shortness of breath, wheezing, cough, and chest tightness at work, during the evening, or at night. A detailed cllnical and occupational history was taken for each subject, and lung function measurement and skin intradermal tests for common allergens were conducted. Airway responsiveness to methacholine was assessed before subjects were exposed for 30 minutes to 0.02 part per million **toluene** diisocyanate in an exposure chamber. Eight hours after **toluene** diisocyanate inhalation, airway responsiveness to methacholine was again determined. Forced expiratory volume was the measure of airway responsiveness. Although methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, the challenge went into the asthmatic range after **toluene** diisocyanate inhalation. Airway responsiveness increased significantly 8 hours after **toluene** diisocyanate challenge in the subjects and was accompanied by a decrease in forced expiratory volume. The late asthmatic reaction began between 3 and 5 hours asthma can be induced by **toluene** diisocyanate in the absence of airway responsiveness.

Protective Equipment & Clothing :

Three commercial air-purifying respirators for protection against **toluene** diisocyanate vapors were evaluated. The Willson R-21 and Survivair, organic vapor cartridges, and the disposable, valveless 3M-8711 were the three respirators evaluated. Each respirator/cartridge was tested three times at 0.2 ppm **toluene** diisocyanate concn for 40 hr and once for 20 hr or more at concn greater than 1.5 ppm **toluene** diisocyanate. All cartridges/respirators had the capacity to provide the required protection against **toluene** diisocyanate vapors. Additional considerations in the respirator selection process included the training and experience of the respirator user, the enforcement of the respirator program, fit of the respirator, knowledge of **toluene** diisocyanate concn onsite, presence of other solvents or chemicals in the air which may adversely affect the capacity of the respirato for **toluene** diisocyanate, and the high odor threshold of **toluene** diisocyanate that makes it impossible for the user to receive advance warning of a leak.

Analytic Laboratory Methods :

A solvent free sampling method for airborne **toluene** diisocyanate was described. Air samples were collected on quartz fiber filters impregnated with 1-(2-methoxyphenyl)piperazine. **Toluene** diisocyanate in the samples reacted with 1-(2-methoxyphenyl)piperazine to form urea derivatives which after dissolution in methanol were analyzed by reversed or normal phase HPLC. When reversed phase HPLC was used, a C18 bonded phase column was utilized. A

- Record Length

cyano amino bonded phase column was used with normal phase HPLC. An ultraviolet detector set at a wavelength 250 nanometers was also used. Detection limits for a 15 liter air sample based on a 5 mm peak height were 0.02 to 0.04 mg/cu m, corresponding to 0.5 to 1 nanograms of **toluene** diisocyanate injected. The method was used to sample laboratory generated **toluene** diisocyanate containing atmospheres over the relative humidity range 11 to 75% and temperature range 20 to 50 deg C. In the study of the effects of humidity, samples were also collected with gas bubblers and silica gel tubes for comparison purposes. **toluene** diisocyanate concn in the collected samples increased linearly with incr temperature. When the samples were collected on the 1-(2-methoxyphenyl)piperazine coated fibers the collected **toluene** diisocyanate concn were not affected by changes in relative humidity. Collection efficiency of the bubblers and silica gel tubes decr for humidities in excess of 45%. It was concluded that the 1-(2-methoxyphenyl)piperazine impregnated quartz fiber filter method for **toluene** diisocyanate sampling is convenient and efficient, and that collection efficiency does not appear to be affected by humidity.

Human Toxicity Excerpts :

An outbreak of occupational asthma due to **toluene** diisocyanate among industrial workers was described. Four employees at a velcro/like tape manufacturing factory in Taipei, Taiwan were seen in an outpatient clinic complaining of cough, shortness of breath, and wheezing. The symptoms became worse at night and improved after long holidays. The patients' job involved applying an adhesive to the tape. Thirty eight of 45 employees were interviewed by questionnaire and given pulmonary function tests. The pulmonary function tests were given during a workday, after a 10 day holiday, and 5 mo after control measures such as process isolation, improved ventilation, and substitution for **toluene** diisocyanate were instituted. Industrial hygiene sampling for **toluene** diisocyanate was conducted. Fourteen workers had symptoms of asthma or asthmatic bronchitis. The highest attack rate occurred in workers employed in the tape processing area where the adhesive was applied. Workers in the tape processing area also showed the greatest decr in 1 second forced expiratory volume and forced vital capacity over the workday. Mean **toluene** diisocyanate concn ranged from 0.012 to 0.047 ppm, the highest occurring in the tape processing area and the lowest in the weaving area. The prevalence of asthmatic symptoms was significantly correlated with **toluene** diisocyanate concn. The forced expiratory volume in 1 second and forced vital capacity values were significantly improved after the 10 day holiday and 5 mo after the control methods were instituted. No asthmatic symptoms were reported after 5 mo. It was concluded that **toluene** diisocyanate was responsible for the outbreak and improving the work environment was effective in reducing exposure to **toluene** diisocyanate.
[Wang JD et al; Am J Ind Med 14 (1): 73-8 (1988)]**PEER REVIEWED**

Human Toxicity Excerpts :

The effect of cessation of exposure to **toluene** diisocyanate was studied in six patients with **toluene** diisocyanate induced asthma, proved by a positive inhalation challenge with **toluene** diisocyanate. Bronchial challenges with **toluene** diisocyanate and methacholine were performed, and lobar bronchial biopsies were taken at diagnosis and 6 mo later, after cessation of exposure. Biopsies from four nonasthmatic control subjects were also examined. At diagnosis, asthmatic subjects had thickened reticular basement membrane ($p < 0.05$) and increased numbers of mononuclear cells ($p < 0.05$) and eosinophils ($p < 0.05$) in the lamina propria when compared with control subjects. Electron microscopy showed degranulation of eosinophils and mast cells in asthmatics. Six months after cessation of exposure, the thickness of reticular basement membrane was significantly reduced compared with that at diagnosis ($p < 0.05$), and it decr to values similar to those of control biopsies. Inflammatory cell numbers in bronchial mucosa of asthmatic subjects did not change significantly 6 mo after removal from exposure, and degranulation of eosinophils and mast cells was still present. At the end of the study, airwa hyperresponsiveness to methacholine and/or sensitivity to **toluene** diisocyanate persisted in most of the asthmatic patients despite the cessation of exposure and the disappearance of asthmatic symptoms. In conclusion, in patients with occupational asthma induced by **toluene** diisocyanate, the avoidance of exposure to the sensitizing agent for 6 mo is

able to reverse the reticular basement membrane thickening in the bronchial mucosa, but th inflammatory cell infiltrate, the specific sensitivity to **toluene** diisocyanate, and the nonspecific airway hyperreactivity may persist.
[Saetta M et al; Am Rev Respir Dis 145 (1): 169-74 (1992)]**PEER REVIEWED**

Human Toxicity Excerpts :

Among the painters handling polyurethane varnish in two furniture manufacturing factories with high **toluene** diisocyanate exposure (0.79 mg/cu m and 0.31 mg/cu m), 26.3% and 15% subjects, respectively displayed asthmatic symptoms, lung function loss, and an increment in mast cell degranulation percentage specific to **toluene** diisocyanate. Some cases of **toluene** diisocyanate linked contact dermatitis were also found among them, being elucidated by positive patch testing to **toluene** diisocyanate. However, the previous abnormalities could not be verified among the painters from another factory with **toluene** diisocyanate concn below the TLV of it (0.11 mg/cu m). It was concluded that both pulmonary hypersensitivity and contact sensitization to **toluene** diisocyanate had occurred in some of the painters included in this study, and that the immunologic effects of **toluene** diisocyanate was concn dependent.
[Huang J et al; Arch Environ Contam Toxicol 21 (4): 607-11 (1991)]**PEER REVIEWED**

Human Toxicity Excerpts :

Pulmonary function tests were done and compared to current and past potential exposure levels of **toluene** diisocyanate for 57 **toluene** diisocyanate manufacturing workers and 89 workers not exposed to **toluene** diisocyanate or other known respiratory hazards. The average **toluene** diisocyanate plant experience was 4.1 yr (standard deviation = 2.8). Routine industrial hygiene measurements have shown **toluene** diisocyanate exposure below a time-weighted average of 0.005 ppm and a short-term exposure level of 0.02 ppm. A certified industrial hygienist ranked department and job classification by level of potential exposure to **toluene** diisocyanate (none, low, moderate, and high). A questionnaire was administered to determine the prevalence of respiratory symptoms and smoking habits. Using backward regression analysis, cumulative pack-years of cigarette smoking and prevalence of lower respiratory symptoms were statistically significant predictors of a standardized forced expiratory volume at 1 second; however, **toluene** diisocyanate exposure, whether classified as current, highest career level, cumulative, or cumulative highest-to-date, was not associated with a decline in forced expiratory volume.
[Olsen GW et al; J Occup Med 31 (8): 664-7 (1989)]**PEER REVIEWED**

Mechanism of Action :

Isocyanates are an important cause of occupational asthma. The mechanism of isocyanate induced asthma is still unknown. To determine whether **toluene** diisocyanate stimulates the 'efferent' function of peripheral endings of capsaicin-sensitive sensory nerves, we investigated the effect of **toluene** diisocyanate in the rat isolated urinary bladder, a preparation in which the action of capsaicin has been well characterized. **Toluene** diisocyanate (0.03 mM) produced a concn dependent contraction of the bladder strips. It maximal effect was about 50 % of the response to capsaicin (1 uM). Previous exposure of the strips to capsaicin followed by washing out produced complete unresponsiveness, both to the first exposure to **toluene** diisocyanate and to a second exposure of capsaicin. Further, the response to both **toluene** diisocyanate and capsaicin was completely prevented by extrinsic bladder denervation, achieved by bilateral removal of pelvic ganglia (72 hr before). Repeated exposure of the rat bladder to **toluene** diisocyanate reduced the capsaicin-evoked release of calcitonin gene-related peptide like immunoreactivity (CGRP-LI), taken as biochemical marker of activation of these sensory nerves. These experiments provide the first evidence that **toluene** diisocyanate activates directly or indirectly the efferent function of capsaicin-sensitive primary sensory nerves.

Non-Human Toxicity Excerpts :

The **toluene** diisocyanate induced delayed type hypersensitivity reaction in the ear of male mice

was investigated and compared with the picryl chloride induced one. The results obtained were as follows: 1) When 1% **toluene** diisocyanate solution (20 ul/ear) as a challenging concentration was used for 7 week old ICR mice, distinct ear swelling was observed in every group sensitized with various concentrations (1-5%, 100 ul/animal) of **toluene** diisocyanate solution, and the swelling rate was the same or higher than that of picryl chloride induced delayed type hypersensitivity. 2) Five, 7 and 13 week old ICR mice showed a similar high response in TDI induced delayed type hypersensitivity, whereas the reactivity of 16 week old ICR mice was significantly lower than that of the above mentioned younger mice. 3) In both **toluene** diisocyanate and picryl chloride induced delayed type hypersensitivity reaction, ICR and BALB/c mice showed a similar high response, whereas the reactivity of ddY mice was significantly lower. The effects of dexamethasone and indomethacin were investigated with the **toluene** diisocyanate induced delayed type hypersensitivity model. The delayed type hypersensitivity reaction was suppressed significantly by both drugs, but the suppressive effects of dexamethasone were higher than that of indomethacin. All the above results indicate that the **toluene** diisocyanate induced delayed type hypersensitivity model in mice taking dye leakage as an index may be useful for evaluation of drugs for disorders derived from delayed type hypersensitivity reactions.

Non-Human Toxicity Excerpts :

The changes in airway responsiveness to increasing doses of an acetylcholine aerosol in anesthetized and ventilated guinea pigs 2, 6, or 24 hr after exposure to air or 1 ppm **toluene** diisocyanate were examined. Pulmonary resistance after the animals inhaled a buffered saline aerosol was used as baseline and was similar for air and groups. The concentration of acetylcholine calculated to cause a 200% increase in pulmonary resistance was significantly lower for animals studied at 2 hr (0.68%) or at 6 hr (0.77%), but not at 24 hr (2.39%), after than for air animals (3.07%). The increase in airway responsiveness in the exposed animals was associated with histologic changes in the trachea and intrapulmonary airways. Exposure to 2 ppm caused a patchy loss of cilia, shedding of epithelial cells into the airway lumen, and an influx of inflammatory cells into the trachea and other airways. In the lamina propria of the trachea, the concentration of extravascular polymorphonuclear leukocytes was 13 to 26-fold greater in animals studied 2 or 6 hr after exposure to 2 ppm **toluene** diisocyanate or at 2 hr after 1 ppm **toluene** diisocyanate than in animals exposed to air. The concentration of polymorphonuclear leukocytes in the epithelium was significantly increased only in animals examined 2 hr after 2 ppm **toluene** diisocyanate. Exposure to **toluene** diisocyanate also caused an influx of eosinophils into the tracheal mucosa. This influx occurred later and was more persistent than the influx of polymorphonuclear leukocytes. These results indicate that a single exposure to **toluene** diisocyanate can cause an increase in airway responsiveness that is associated with epithelial injury and acute airwayinflammation.
[Gordon T et al; Am Rev Respir Dis 132 (5): 1106-12 (1985)]**PEER REVIEWED**

Human Toxicity Excerpts :

A study of individuals with occupational asthma induced by **toluene** diisocyanate was conducted. This was a followup of 35 patients, 25 males, with a history of isocyanate sensitization. They had 3 to 41 years' occupational exposure to isocyanate compounds. The subjects had been diagnosed with isocyanate asthma on the basis of their response to bronchial challenge with **toluene** diisocyanate. They were examined an average of 11 mo after diagnosis. They underwent bronchial challenge with **toluene** diisocyanate and methacholine. Forced expiratory volumes in 1 second were measured. Symptoms reported by the subjects were recorded. Twenty seven subjects were still asthmatic at followup as shown by a positive reaction to **toluene** diisocyanate challenge. They showed a deterioration in their forced expiratory volumes in 1 second and response to methacholine similar to that seen at diagnosis. Seventy seven percent of these subjects continued to have recurring attacks of dyspnea, wheezing, and cough which required medication. Twenty two of the asthma subjects had been removed from exposure. Subjects who recovered (did not react to **toluene** diisocyanate at the followup examination) showed an improvement in their forced expiratory volumes in 1 second and a reduced response to methacholine. At the time of diagnosis they tended to have an

immediate or dual asthmatic reaction and were younger than the other subjects. The asthmatic subjects had dual or late reactions at diagnosis. It was concluded that respiratory symptoms, isocyanate sensitization, and airway hyperresponsiveness may persist for some time after exposure to **toluene** diisocyanate has ended.
[Mapp CE et al; Am Rev Respir Dis 137 (6): 1326-9 (1988)]**PEER REVIEWED**

Metabolism/Metabolites :

A technique for detectingurinary amine metabolites in rats exposed to **toluene** diisocyanate was evaluated. Skin tissue of rats was exposed to 40% **toluene**-2,4-diisocyanate solution in di-n-butyl-ether liquid. Rats were exposed daily for 3 hr on 4 consecutive days. Urine was collected in metabolic cages for 18 hr after the last exposure. Chromatographic techniques were used for nitrogen selective detection of nonderivatized amines. An autolinear temperature programmer was employed to analyze derivatized amine. The identity of the amine was confirmed by gas chromatography/mass spectrometry. A linear correlation was found between **toluene**-2,4-diamine added to urine and peak height. Peak height and recovery from the non hydrolyzed and from the hydrolyzed urine was about 85 and 70%, respectively. No free **toluene**-2,4-diamine or free **toluene**-2,4-diisocyanate was detected in the urine of rats exposed to **toluene**-2,4-diamine in hydrolyzed urine was 1.5 micrograms per milliliter. Gas chromatography/mass spectrometry confirmed the identity of the amine. /This/ highly sensitive technique tested is easy to apply and is effective for trace assays of amines.
[Rosenberg C; J Chromatography 323 (2): 429-33 (1985)]**PEER REVIEWED**

Human Toxicity Excerpts :

Diisocyanate inhalation tests (maximal concn, 20 ppb; exposure time, 1-2 hr) were performed using **toluene** diisocyanate (TDI, n = 15) and diphenylmethane diisocyanate (MDI, n = 7) as well as methacholine challenges in 19 workers who had a clinical history of **toluene** diisocyanate/diphenylmethane diisocyanate induced asthma. Additionally volunteers were tested who had n previous contact with diisocyanates: 10 healthy individuals with a negative methacholine test and 14 patients with asthma and a positive methacholine test were exposed to **toluene** diisocyanate. In all, 1 of the normal volunteers and 3 of the patients with asthma unrelated to diisocyanates showed a positive airway reaction to **toluene** diisocyanate, and 13 of the 19 diisocyanate workers displayed a positive result in the **toluene** diisocyanate/diphenylmethane diisocyanate inhalation test; however, only 6 of these 13 individuals reacted to methacholine. Furthermore, 3 of the 6 patients with a negative **toluene** diisocyanate/diphenylmethane diisocyanate challenge test demonstrated a significant response to methacholine. It was concluded that bronchial hyperreactivity as evaluated by the methacholine challenge test is not closely related to isocyanate induced bronchoconstriction and, therefore, the metacholine challenge is only of limited diagnostic value in patients with suspected isocyanate induced asthma.
[Vogelmeier C et al; Int Arch Occup Environ Health 63 (1): 9-13 (1991)]**PEER REVIEWED**

Mechanism of Action :

To determine whether early and/or late asthmatic responses induced by **toluene** diisocyanate are caused by a reflex mechanism involving stimulation of muscarinic receptors, we studied the effect of the muscarinic antagonist atropine on early and late airway response induced by **toluene** diisocyanate. A preliminary study was conducted in asthmatics to assess whether the selected dose of atropine provided adequate muscarinic blockade. On different days we measured the provocation dose (in mg) of carbachol causing a 15% decrease in forced expiratory volume in 1 second (PD15FEV1) without and with atropine premedication (0.008 or 0.012 mg/kg sc atropine 30 or 90 min before carbachol challenge test). 0.008 to 0.012 mg/kg sc atropine increased the PD15FEV1 carbachol by 6 to 10 fold, inducing a consistent and prolonged decrease in nonspecific bronchial hyperresponsiveness to cholinergic agent. 10 Subjects with a history of sensitization to **toluene** diisocyanate were then examined in 2 sets of experiments. In the first set of experiments, the subjects were studied before and after exposure to **toluene** diisocyanate (0.04 ppm; 30 min) after no treatment. In the second set of experiments, carried out 1 to 2 wk later, the same procedure was repeated after treatment with atropine (0.008

to 0.012 mg/kg atropine sulfate administered sc 30 min before **toluene** diisocyanate challenge, and then at 90 min intervals after **toluene** diisocyanate exposure); all patients showed symptoms of atropine effect (dryness of mouth, cycloplegia, increased heart rate).
[Paggiaro P et al; Am Rev Respir Dis 136 (5): 1237-41 (1987)]**PEER REVIEWED**

Human Toxicity Excerpts :

An investigation of the persistence of isocyanate induced asthma in workers with negligible occupational exposure was carried out. Six asthmatic workers, proven to be **toluene** diisocyanate sensitive by inhalation challenge testing in a longitudinal study of respiratory health risks associated with polyurethane foam production, were examined. The subjects were followed for 5 yr during which they completed a respiratory symptom questionnaire annually. Pulmonary function and responsiveness to methacholine challenge were measured annually. **toluene** diisocyanate concn in their breathing zones were measured. After the original survey the six subjects were transferred to areas thought to have negligible **toluene** diisocyanate exposures. None of the subjects had respiratory or asthmatic complaints before they started work in polyurethane production. The respiratory symptoms of the subjects did not improve during the followup period. All six had bronchial hyperresponsiveness to methacholine that did not resolve over time. Three subjects demonstrated deficits in 1 second forced expiratory volume of greater than 15% on one of the testing days during the followup period. The need for less or additional asthma therapy of the subjects could not be predicted. The mean time weighted average **toluene** diisocyanate exposure experienced by the subjects was 0.64 ppb; less than 5% of the OSHA standard of 20 ppb. It was concluded that although the outcome of isocyanate induced asthma cannot be predicted, the asthmatic symptoms of these workers have persisted despite the negligible **toluene** diisocyanate exposures.

Non-Human Toxicity Excerpts :

THE POSSIBILITY OF DERMAL EXPOSURES TO **TOLUENE** DIISOCYANATE RESULTING IN PULMONARY SENSITIVITY WAS INVESTIGATED USING GUINEA PIGS AS AN ANIMAL MODEL. **TOLUENE** DIISOCYANATE (1-100% CONCN) WAS APPLIED TO DORSAL SITES ON GUINEA PIGS, WHERE SKIN SENSITIVITY TO TDI WAS APPARENT BY THE 7TH DAY. AFTER 14 DAYS, ANIMALS WERE ADDNL EVALUATED FOR TDI SENSITIVITY BY SEROLOGIC ANALYSIS & BRONCHIAL PROVOCATION CHALLENGE. ANTIBODIES TO **TOLUENE** DIISOCYANATE WERE DETECTED USING PASSIVE CUTANEOUS ANAPHYLAXIS, DOUBLE DIFFUSION IN GEL, & RADIOLABELED ANTIGEN BINDING ASSAYS. ANTIBODIES WERE SPECIFIC FOR **TOLUENE** DIISOCYANATE. THE DEVELOPMENT OF RESPIRATORY HYPERSENSITIVITY AS A RESULT OF DERMAL CONTACT WITH **TOLUENE** DIISOCYANATE EMPHASIZES THE IMPORTANCE OF CAREFUL WORKPLACE PRACTICES & SUGGESTS REEVALUATION OF THE ROLE OF INHALATION &/OR DERMAL CONTACT IN CAUSING PULMONARY SENSITIZATION OF WORKERS.
[KAROL MH ET AL; TOXICOL APPL PHARMACOL 58 (2): 221 (1981)]**PEER REVIEWED**

Mechanism of Action :

In order to determine whether treatment with ketotifen inhibits asthmatic reactions induced by **toluene** di-isocyanate, six sensitized subjects with previously demonstrated dual or late asthmatic reaction after inhalation challenge with **toluene** diisocyanate were studied. Ketotifen (1 mg bid, orally) or placebo was administered for 7 days to the examined subjects, according to a double-blind, cross-over, placebo controlled study design. When the subjects were treated with either ketotifen or placebo, forced expiratory volume in 1 second markedly decr after exposure to **toluene** diisocyanate. These results suggest that the anti-asthmatic agent ketotifen is not effective in **toluene** diisocyanate induced asthma and suggest that it should not be used in the prophylaxis of asthmatic reactions induced by **toluene** diisocyanate in sensitized subjects.
[Tossin L et al; Clin Exp Allergy 19 (2): 177-82 (1989)]**PEER REVIEWED**

Mechanism of Action :

To determine the importance of airway inflammation for the development of late asthmatic reactions, we examined sensitized subjects during late asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. Late asthmatic reactions are associated with a transient increase of bronchial responsiveness and, at the same time, with an increase of neutrophils followed by eosinophils, and of leukotriene B4 and albumin in bronchoalveolar lavage fluid. Late asthmatic reactions, increased bronchial responsiveness, and increase of neutrophils, eosinophils, leukotriene B4, and albumin concn in bronchoalveolar lavage induced by exposure to **toluene** diisocyanate are all prevented by pretreatment with prednisone but not with the nonsteroidal anti-inflammatory agent indomethacin. Aerosolized steroids (beclomethasone and dexamethasone isonicotinate) completely inhibit late asthmatic reactions induced by **toluene** diisocyanate, whereas theophylline has a partial, and verapamil, ketotifen, and cromolyn have no protective effect. These results suggest that late asthmatic reactions induced by **toluene** diisocyanate may be caused by airway inflammation, and that anti-inflammatory steroids should be recommended in the prophylaxis of **toluene** diisocyanate asthma.
[Fabbri LM et al; Am Rev Respir Dis 143 (3 Pt 2): 537-8 (1991)]**PEER REVIEWED**

Mechanism of Action :

The influence of cyclophosphamide induced granulocyte depletion on **toluene** diisocyanate related changes in airway reactivity and pathology was assessed in guinea pigs. Twelve cyclophosphamide-treated and 12 control animals comprising each group were studied physiologically before and 2 hr after a single 10 min exposure to 3 ppm of **toluene** diisocyanate. Reactivity was determined in intact unanesthetized animals by measuring specific airway conductance before and during intravenous acetylcholine infusion. After testing, tracheal tissue for light microscopic examination was obtained from three hyperreactive guinea pigs in each exposed group and compared with tissue from treated and control animals (n = 3 each) that had not been **toluene** diisocyanate exposed. Cyclophosphamide treatment caused substantial decr in both circulating and airway granulocyte counts. However, the incidence and degree of bronchial hyperreactivity that occurred 2 hr post-**toluene** diisocyanate was similar in the untreated and treated groups. Results indicate that **toluene** diisocyanate induced bronchial hyperreactivity 1) occurs shortly after a brief high concn exposure and 2) appears independent of circulating or airway granulocyte counts.
[Cibulas W Jr et al; J Appl Physiol 64 (5): 1773-8 (1988)]**PEER REVIEWED**

Mechanism of Action :

A study of the occurrence of serum immunoglobulin-E and immunoglobulin-G antibodies in workers with isocyanate induced asthma was conducted. The study group consisted of 62 workers (58 males) being evaluated for occupational asthma. Thirty nine had been exposed to hexamethylene diisocyanate, 17 to diphenylmethane diisocyanate, and six to **toluene** diisocyanate. The subjects completed a respiratory and occupational questionnaire. Spirometric tests were administered. Skin prick tests were performed with 15 common inhalant allergens and **toluene** diisocyanate, hexamethylene diisocyanate, and diphenylmethane diisocyanate human serum albumin conjugates. Blood samples were collected and assayed for specific serum immunoglobulin-G and immunoglobulin-E antibodies to hexamethylene diisocyanate, diphenylmethan diisocyanate, and **toluene** diisocyanate. Specific inhalation challenges were conducted with hexamethylene diisocyanate, diphenylmethane diisocyanate, and **toluene** diisocyanate. Specific inhalation challenge with **toluene** diisocyanate, hexamethylene diisocyanate, or diphenylmethane diisocyanate induced significant bronchoconstriction in half of the subjects, late reactions being the most common. Twenty subjects had significantly elevated immunoglobulin-G concn and nine had significantly elevated immunoglobulin-G plus immunoglobulin-E concn. Six of 12 subjects with elevated immunoglobulin-E and immunoglobulin-G antibodies had positive skin prick tests for hexamethylene diisocyanate and one was sensitized to diphenylmethane diisocyanate. It was concluded that an association between isocyanate specific antibodies and the results of specific inhalation challenge tests has been established. This suggests that isocyanate induced asthma may involve an immunological mechanism.
[Cartier A et al; J Allergy Clin Immunol 84 (4 Part 1): 507-14

(1989)]**PEER REVIEWED**

Mechanism of Action :

To investigate the role of pharmacological mechanisms in **toluene** diisocyanate induced occupational asthma, the effects of **toluene** diisocyanate on rat trachea ring and lung parenchymal strip were studied in vitro. The most prominent effect observed was a stimulation of metacholine induced contraction of the tracheal ring by 1M **toluene** diisocyanate (added in dimethyl sulfoxide). The results were less pronounced when **toluene** diisocyanate was added from a stock solution prepared in water, which is possibly due to copolymerisation. It is concluded that the pharmacological effect of **toluene** diisocyanate may result from an autonomic imbalance between cholinergic and B-adrenergic neural control.

Mechanism of Action :

SERUM FROM 26 PERSONS SHOWN TO REACT TO PROVOCATIVE INHALATION CHALLENGE WITH LOW CONCN OF **TOLUENE** DIISOCYANATE WAS TESTED BY RADIOALLERGOSORBENT TEST (RAST) USING A P-TOLYL ISOCYANATE-HUMAN SERUM ALBUMIN (TMI-HSA) CONJUGATE. POSITIVE RESULTS WERE OBTAINED IN 15-19% OF **TOLUENE** DIISOCYANATE REACTORS, DEPENDING ON THE METHOD OF EVALUTION. **TOLUENE** DIISOCYANATE ASTHMA MAY BE A COMPLEX SYNDROME WITH SEVERAL TYPES OF REACTIONS POSSIBLE, INCLUDING AN IMMUNOGLOBULIN-E MECHANISM IN SOME INDIVIDUALS. THE THEORY THAT **TOLUENE** DIISOCYANATE ASTHMA IS BASED SOLELY ON AN IMMUNE MECHANISM IS NOT SUPPORTED. THE FINDINGS DO NOT DISAGREE WITH THE HYPOTHESIS THAT **TOLUENE** DIISOCYANATE REACTIVITY MAY BE MEDIATED BY A PHARMACOLOGIC MECHANISM.
[BUTCHER BT ET AL; J ALLERGY CLIN IMMUNOL 66 (3): 213 (1980)]**PEER REVIEWED**

Mechanism of Action :

Intravenously administered endotoxin inhibits the polymorphonuclear leukocyte dependent airway edema produced in guinea pigs exposed to **toluene** diisocyanate. Tumor necrosis factor is produced in vivo by peripheral blood monocytes and tissue macrophages stimulated with endotoxin and has been shown to activate polymorphonuclear leukocyte's and vascular endothelial cells. To determine whether the inhibition of airway edema is mediated by tumor necrosis factor, guinea pigs were treated with intravenous saline or 75,000 U/kg recombinant human tumor necrosis factor 1.5 hr before exposure to air or 3 ppm **toluene** diisocyanate for 1 hr. Animals were then injected intravenously with 50 mg/kg Evans blue dye as a marker of protein extravasation. Saline-treated animals exposed to **toluene** diisocyanate had a significant increase in tracheal Evans blue dye extravasation (85 + or - 6.5 ug dye/g trachea, mean + or - standard error) compared with saline-treated animals exposed to air (31.3 + or - 2.5, $P < 0.001$). The tracheal extravasation of Evans blue dye was significantly inhibited ($P < 0.05$) in **toluene** diisocyanate exposed animals treated with tumor necrosis factor (64.7 + or - 7.5). Neither heat-inactivated tumor necrosis factor (104.9 + or - 9.5) nor tumor necrosis factor neutralized with a monoclonal antibody against tumor necrosis factor (99.7 + or - 17.9) inhibited **toluene** diisocyanate induced airway edema. In addition, treatment with 15,000 U/kg (99.9 + or - 21.3) or 150,000 U/kg (103.2 + or - 17.6) interleukin 1, a monokine also produced in response to endotoxin, did not prevent airway edema. These results suggest that tumor necrosis factor released in response to endotoxin mediates endotoxin's inhibition of a polymorphonuclear leukocyte dependent airway edema.
[Gordon T, Sheppard D; J Appl Physiol 64 (4): 1988 1688-92]**PEER REVIEWED**

Mechanism of Action :

Light and electron microscopic structure of lobar bronchial biopsies were examined of nine subjects with occupational asthma induced by **toluene** diisocyanate and of four control nonasthmatic subjects who had never been exposed to **toluene** diisocyanate. Inflammatory cell

numbers were separately assessed in the intact epithelium, in the more superficial layer of the submucosa, and in the total submucosa. Asthmatic subjects had an increased number of inflammatory cells in the airway mucosa compared with control subjects. Eosinophils were significantly increased in all compartments, CD45-positive cells were significantly increased in the epithelium and in the more superficial layer of the submucosa, and mast cells were significantly increased only in epithelium. By electron microscopy eosinophils and mast cells appeare degranulated only in asthmatic patients. In the areas of epithelium that appeared intact by light microscopy, electron microscopy showed that, although the intercellular spaces between columnar cells were similar in asthmatic and control groups, the intercellular spaces between basal cells were significantly wider in patients with asthma. Patients with **toluene** diisocyanate induced asthma also had a thicker subepithelial reticular layer, where immunohistochemistry showed the presence of collagen III. In conclusion, in patients with asthma induced by **toluene** diisocyanate, the airway mucosa shows pathologic features, such as inflammatory cell infiltrate and thickening of subepithelial collagen, similar to those described in atopic asthma.

Probable Routes of Human Exposure :

In a Finnish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(1). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(1). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4-isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(1). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(1). TDI levels of 1.3-2.8 ppb were detected in air inside a Swedish factory manufacturing polyurethanes(2).
[(1) Rosenberg C, Savolainen H; J Chromatography 367: 385-92 (1986) (2) Audunsson G et al; Intern J Environ Anal Chem 20: 85-100 (1985)]**PEER REVIEWED**

Analytic Laboratory Methods :

A passive monitor for **toluene** diisocyanate which utilizes microporous Teflon diffusion membranes and a 0.5% sulfuric acid absorbing medium was evaluated. The collection rate of **toluene** diisocyanate is proportional to exposure dose from 10 to at least 300 ppb.hr, and response is equivalent for 2,4- and 2,6-**toluene** diisocyanate. Collection rate is independent of humidity and normal atmospheric pressure variations, while temperature causes a decrease of 1.0% per deg C. Negative interference caused by ambient nitrogen dioxide is eliminated by addition of sulfamic acid to the collecting medium. N-Ethylmorpholine is a positive interferent. Field testing of the sampler against a reference impinger technique indicated a positive bias when **toluene** diisocyanate is aerosolized.
[Rando RJ et al; Am Ind Hyg Assoc J 50 (1): 8-14 (1989)]**PEER REVIEWED**

Environmental Fate/Exposure Summary :

Commercial **toluene** diisocyanate (TDI) is composed of 2 isomers. 2,4-**Toluene** diisocyanate constitutes roughly 80% of TDI, the other 20% being the 2,6-isomer. It may be released to the environment as fugitive emissions and from stack exhaust during the production, transport, and use of TDI in the manufacture of polyurethane foam products and coatings as well as from spills. The types of reactions which the isomers undergo are similar, although the rates may differ. The reactivity of the 2,4-**toluene** diisocyanate with active hydrogen is greater than with the 2,6-isomer, therefore the percentage of 2,4-**toluene** diisocyanate in monitored TDI is generally much less than the 80% in the commercial mixture. However, since much of the monitoring data do not distinguish between isomers, it is not possible to know the proportion of the isomers in the TDI. If spilled on wet land, TDI is rapidly degraded. In one experiment simulating a spill, 5.5% of the original material remained after 24 hours and in a field situation, the concentration of TDI had declined to the ppm levels in 12 weeks. If released into water, a crust forms around the liquid TDI and <0.5% of the original material remains after 35 days. Low concentrations of TDI disappear from the aqueous environment in approximately a day. In

the atmosphere, TDI reacts with photochemically produced hydroxyl radicals (half-life 3.3 hr) and is also removed by dry deposition. Human exposure is primarily occupational via inhalation and dermal contact. (SRC)
PEER REVIEWED

Human Toxicity Excerpts :

A survey of the incidence of occupational asthma in a steel coating factory was conducted. The survey was prompted by two male employees developing symptoms suggestive of occupational asthma. The cohort consisted of 221 males employed in the coating shop. A respiratory questionnaire was administered. Spirometric tests were conducted. Peak expiratory flow rate studies were performed on 50 subjects. Twenty one subjects reported symptoms of occupational asthma. Sixty three had other work related symptoms and 58 had respiratory symptoms unrelated to work. The mean length of employment of the subjects with asthmatic symptoms was 7.7 years. All symptomatic subjects had significantly reduced 1 second forced expiratory volumes, compared to asymptomatic workers. 21% of the peak expiratory flow rates were indicative of work related asthma. Two symptomatic subjects were administered inhalation challenge tests with **toluene** diisocyanate after it was discovered that one of the coatings that had been used for 8 years released **toluene** diisocyanate during the coating process. Both subjects showed decreases in forced expiratory volumes of at least 15% below the baseline values. Environmental sampling for **toluene** diisocyanate indicated concentrations ranging from below 0.001 to 0.026 ppm. The coating containing **toluene** diisocyanate was removed from the process. A follow-up survey conducted 1 year later showed that 17 of the symptomatic subjects had become asymptomatic or improved.

Human Toxicity Excerpts :

The prevention of airway inflammation caused by **toluene** diisocyanate by prednisone was studied. Healthy **toluene** diisocyanate sensitive individuals were exposed to 0.018 ppm **toluene** diisocyanate in a test chamber. Bronchoalveolar lavage fluid was collected with a flexible fiberoptic bronchoscope. The lavage fluid was spun in a cytocentrifuge and stained with May/Grunwald/Giemsa for differential cell count. The total cell count was performed on resuspended cell pellets. A late asthmatic response was characterized by the occurrence of less than 20% of free expiratory volume in 1 second. The airway responsiveness was assessed by the reaction to methacholine. The cumulative dose of methacholine that produced a 20% decrease in forced expiratory volume in 1 second was used to measure airway responsiveness. Five subjects who received no prednisone treatment developed a late or dual asthmatic reaction. The albumin concn and total number of cells increased in subjects that were given no prednisone compared to controls. There was a significant increase in the number of neutrophils and a small increase in eosinophilia. There was no significant difference in the counts of other cell types. Results suggest that **toluene** diisocyanate induce late asthmatic reactions causing airway inflammation and that prednisone inhibits these reactions.

Metabolism/Metabolites :

Epithelial injury and inflammation are involved in airway hyperresponsiveness and asthma induced by **toluene** diisocyanate. In that isocyanates are insoluble and highly reactive compounds, bronchial epithelial cells may represent the most important target cells of their toxic effect. We hypothesized that damage to airway epithelium by **toluene** diisocyanate may result in the release of metabolites of arachidonic acid, which are known to promote inflammation and to alter epithelial cell function and airway smooth muscle responsiveness. To test this hypothesis we examined eicosanoid products in the culture media of bronchial epithelial cells exposed in vitro to 8 and 18 ppb **toluene** diisocyanate. Epithelial cells derived from human bronchi obtained at surgery were cultured to confluency on collagen-coated microporous membranes. Those cells, which expressed differentiated characteristics of epithelial cells (they showed keratin-containing filaments and had a cobblestone appearance), were alternatively exposed to **toluene** diisocyanate or air for 30 min in a specially designed in vitro chamber. The production of metabolites of arachidonic acid was assessed by measuring the release of immunoreactive

products into the cell medium at the end of the exposure and during a 2 hr period after exposure. This method revealed a predominant isocyanate induced release of immunoreactive 15-hydroxyeicosatetraenoic acid. Release rate of this compound tended to be dose-related and was associated with cell damage as assessed by the release of lactate dehydrogenase in the medium.

The following Overview, *** **TOLUENE** DIISOCYANATE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Toluene** diisocyanate is an irritant to skin, lungs, conjunctiva and gastrointestinal tract. Euphoria, ataxia, mental aberrations, sensitization (primarily respiratory), bronchitis, emphysema and cor pulmonale can occur.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Severe conjunctival irritation and lacrimation from liquid or high vapor concentrations is likely. Lower concentrations may produce a burning or prickling sensation.
- Glaucoma and iridocyclitis have been reported with a splash accident.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Burning or irritation of the nose and throat, cough, laryngitis, chest pain, and asthmatic syndrome (chemical bronchitis with severe bronchospasm), sensation of oppression or constriction of the chest, bronchitis, emphysema and cor pulmonale may occur.
- Respiratory symptoms may recur several years after discontinuation of exposure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute exposures may produce headache, insomnia, euphoria, ataxia, anxiety neurosis with depression, or paranoid tendencies.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Inhalation of vapor or aerosol may produce vomiting and abdominal pain. Epigastric and substernal pain may be secondary to the paroxysmal or persistent cough

associated with inhalation.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Irritation and inflammation are common. Dermal absorption is low.

IMMUNOLOGIC

0.2.19.1 ACUTE EXPOSURE

- Elevated specific IgE and IgG antibodies have been detected in sensitized and exposed workers. The presence of antibodies does is an indicator of exposure but not of sensitization.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- **Toluene** diisocynate has been classified as a 2B agent: possibly carcinogenic to humans, based on sufficient evidence of carcinogenicity in experimental animals and no human data (IARC, 1987).

0.2.21.2 HUMAN OVERVIEW

- **Toluene** diisocyanate is considered a suspected or possible human carcinogen, based on sufficient evidence of carcinogenicity or tumors (spleen, subcutaneous, hepatic, ovarian, peritoneum, mammary gland tissues) in experimental animals (IARC, 1987; US DHHS, 1994; ACGIH, 1995).

Laboratory:

- Monitor respiratory function closely.

Treatment Overview:

ORAL EXPOSURE

- Due to the irritant nature of this substance, emesis is not advised.
- DILUTION: Immediately dilute with 4 to 8 ounces (120 to 240 mL) of milk or water (not to exceed 15 mL/kg in a child).
- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- Monitor patient for respiratory distress. If a cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis and pneumonia.
- Allergic reaction: Sensitized individuals should be cautioned to avoid further exposure as serious allergic reactions may result.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- Randomized, double-blind cross-over studies showed minimal efficacy of bronchodilators. This could be due to the absence of airway hyperresponsiveness in some TDI-induced asthma.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes.

If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Available dose-response information concerning humans pertains to inhalational exposure. Concentrations of 2.5 ppm are considered Immediately Dangerous to Life or Health. A fatality in an asthmatic who continued exposure to TDI has been reported.
- The recommended short term exposure limits for TDI in industry is 0.02 ppm. TDI does not have sufficient warning properties (e.g. odor or eye irritancy) at air concentrations below the recommended short term exposure limit.

National Toxicology Program Studies :

Groups of 50 female F344/N rats and 50 female B6C3F1 mice were administered commercial grade **toluene** diisocyanate (80% 2,4- and 20% 2,6-) in corn oil by gavage at doses of 60 or 120 mg/kg body weight, 5 days per week for 105 or 106 weeks. Groups of 50 male F344/N rats received 30 or 60 mg/kg and groups of 50 male B6C3F1 mice received 120 or 240 mg/kg on the same schedule. Dosage analyses of **toluene** diisocyanate indicated that the chemical had reacted in the corn oil vehicle, resulting in actual gavage concentrations 77% to 90% of theoretical values. Groups of 50 rats and 50 mice of each sex received corn oil only and served as vehicle controls. Survival in all groups of dosed rats in the 2-year studies was shorter (P less than or equal to 0.005) than that of the controls; depressions in mean body weight gain relative to controls were greater than 10% in all dosed rat groups throughout most of the study. A dose-dependent pattern of cumulative toxicity began at 70 weeks and culminated in excessive mortality, indicating the estimated maximum tolerated dose had been exceeded for rats. Acute bronchopneumonia occurred at increased incidences in groups of dosed male and female rats (males: control, 2/50; low dose, 6/50; high dose, 14/50; females: 1/50, 10/50, 25/49). /Results indicated that/ commercial grade **toluene** diisocyanate in corn oil was carcinogenic for F344/N rats, causing subcutaneous fibromas and fibrosarcomas (combined) in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland fibroadenomas in females. **Toluene** diisocyanate was not carcinogenic for male B6C3F1 mice. TDI was carcinogenic for female B6C3F1 mice, causing hemangiomas or hemangiosarcomas (combined), as well as hepatocellular adenomas.
[DHHS/NTP; Toxicology and Carcinogenesis Studies of Commercial Grade 2,4 (80%) and 2,6 (20%) - Toluene Diisocyanate (Gavage Studies) p. 7 (1986) Technical Rpt Series No. 251 NIH Pub No. 86-2507]**PEER REVIEWED**

Human Toxicity Excerpts :

The importance of airways inflammation for the development of bronchial hyperresponsiveness and for exacerbation of asthma was investigated in subjects with occupational asthma. Subjects sensitized to isocyanates, a small molecular weight compound that causes occupational asthma were examined. Studies in asthmatic subjects sensitized to **toluene** diisocyanate demonstrated that late, but not early, asthmatic reactions induced by **toluene** diisocyanate were associated

with an acute increase in bronchial responsiveness, and with a marked infiltration of neutrophils and a slight infiltration of eosinophils into the airways, both prevented by steroids. As the late asthmatic reactions and the increase in responsiveness induced by **toluene** diisocyanate were prevented by steroids, but not by indomethacin, it was speculated that cell membrane phospholipid metabolites, which are inhibited by steroids but not by indomethacin, may be involved in **toluene** diisocyanate induced hyperresponsiveness. The results of these studies suggest that bronchial hyperresponsiveness and exacerbation of asthma may be related to inflammation of the airways and that cell membrane phospholipid metabolites may be involved.
[Mapp CE et al; Bull Eur Physiopathol Respir 23 (6): 583-6 (1987)]**PEER REVIEWED**

Human Toxicity Excerpts :

Fifty seven polyurethane foam manufacturing workers and 24 reference workers were followed for 4 yr to clarify the effects on pulmonary function of working in polyurethane foam factories with exposure to **toluene** diisocyanate. No significant differences in the average annual losses of pulmonary function for 4 yr were observed among the 28 polyurethane foam workers whose **toluene** diisocyanate exposure levels were very low (mean = 0.1 ppb, group L), the remaining 29 polyurethane foam workers with mean **toluene** diisocyanate exposure of 5.7 ppb (group H), and the reference workers. However, 15 polyurethane foam workers in group H who had experienced peak exposure excursions to 30 ppb or above with a mean concn of 8.2 ppb showed significantly larger average annual losses in percentage maximal mid-expiratory flow, forced expiratory volume in 1 sec ratio to vital capacity, and forced expiratory flow at 25% of forced vital capacity than expected, and significantly larger average annual losses in some obstructive pulmonary function indices than those of the 14 remaining polyurethane foam workers in group H whose peak exposure excursion levels were 3-14 ppb with a mean time-weighted average of 1.7 ppb, group L, and the reference workers. These findings suggest that the peak exposure excursion level of **toluene** diisocyanate might be important in inducing obstructive pulmonary function changes in the polyurethane foam workers rather than the TWA exposure levels, though further comparative studies of the AAL in those who are exposed to different peak exposure excursion levels but the same mean exposure levels are necessary. From the standpoint of prevention, the proposition that peak exposure excursion levels exceeding 20 ppb should be avoided is reasonable.
[Omae K et al; Int Arch Occup Environ Health 63 (8): 565-9 (1992)]**PEER REVIEWED**

Human Toxicity Excerpts :

The clinical findings and the results of inhalation challenge with **toluene** diisocyanate and methacholine in 113 subjects with a history of exposure to **toluene** diisocyanate and work-related respiratory symptoms are reported. Only some of the subjects (40.7%) had isocyanate asthma, diagnosed by a positive **toluene** diisocyanate inhalation challenge. Most reactors had a dual (30.4%) or a late (41.3%) response. The interval between the last occupational exposure and the specific challenge was significantly shorter in reactors, and among this group the number of immediate reactions to **toluene** diisocyanate decr progressively with an incr interval. The reactors had a significantly higher proportion of positive responses to methacholine and a significantly lower mean PD[1][5] FEV[1] (provocative dose of methacholine which provoked a 15% decrease in forced expiratory volume in 1 second): reactors 557:g, SEM 92.3; non-reactors 1346:g, SEM 128, P < .01. Methacholine challenge could not identify subjects with isocyanate asthma.
[Moscato G et al; J Occup Med 33 (6): 720-5 (1991)]**PEER REVIEWED**

Human Toxicity Excerpts :

To evaluate the morphologic basis of the different outcomes of **toluene** diisocyanate asthma after quitting occupational exposure, ten patients with **toluene** diisocyanate asthma were examined who showed, at diagnosis, a positive **toluene** diisocyanate challenge test and nonspecific bronchial hyperresponsiveness to methacholine. After diagnosis, all patients ceased work and a 4 to 40 mo follow-up was obtained with three to eight determinations of the cumulative dose producing a 15% fall in forced expiratory volume in 1 second to methacholine in each patient. Bronchoalveolar lavage and biopsy of bronchial muscosa were performed 3 to

39 mo after cessation of work, in the absence of acute exacerbations of the disease. Total cell count in bronchoalveolar lavage fluid was moderately increased in four of ten patients, eosinophils were increased in five of ten patients, and neutrophils were increased in eight of ten patients. Mucosal biopsy specimens of main or lobar bronchi were available in eight of ten patients; epithelial damage and thickening of basement membrane was observed in almost all patients, as well as a mild to moderate inflammatory reaction in the submucosa, mainly represented by lymphocytes, eosinophils, and neutrophils. No relationship was observed between the cellularity of bronchoalveolar lavage and the degree of nonspecific bronchial hyperresponsiveness at the time of bronchoalveolar lavage; mean values of total cells and differential count were not different between patients with presence or absence of the different histologic findings. Mucosal biopsy and bronchoalveolar lavage were performed also in four subjects exposed to dusts without respiratory symptoms or nonspecific bronchial hyperresponsiveness; similar findings were obtained except for the absence of eosinophils in bronchoalveolar lavage and a lesser degree of basement membrane thickening and inflammatory reaction in the submucosa. The study of the changes in nonspecific bronchial hyperresponsiveness after quitting exposure showed that five of ten patients had a significant improvement in nonspecific bronchial hyperresponsiveness to methacholine, as evaluated by a positive significant linear regression between months of work cessation and forced expiratory volume in 1 sec of methacholine; only one of these five patients had an increased number of eosinophils in bronchoalveolar lavage fluid. By contrast, four of the five patients with persistent nonspecific bronchial hyperresponsiveness after quitting exposure had an increased number of eosinophil in bronchoalveolar lavage. It is suggested that persistent nonspecific bronchial hyperresponsiveness in **toluene** diisocyanate asthma after cessation of work may be related to an inflammatory reaction in which eosinophil infiltration seems to be a major determinant.
[Paggiaro P et al; Chest 98 (3): 536-42 (1990)]**PEER REVIEWED**

Human Toxicity Excerpts :

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint materials containing **toluene** diisocyanate. His symptoms began 6 to 8 hr after exposure to the agent and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate-human serum albumin was present in bronchoalveolar lavage fluid and sera: IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate-human serum albumin. The histologic findings suggested hypersensitivity pneumonitis. The results of bronchoalveolar lavage, which was repeated on four separate occasions, showed lymphocytosis and a predominance of suppressor cytotoxic T cells. The findings from serial determinations of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to the agent.
[Yoshizawa Y et al; Ann Intern Med 110 (1): 31-4 (1989)]**PEER REVIEWED**

Human Toxicity Excerpts :

A case of building related health complaints was investigated with respect to the relationship among frequency of symptoms, antibodies to albumin conjugates of formaldehyde, **toluene** diisocyanate, and trimellitic anhydride, and volatile organic chemicals. The indoor air concn of volatile organic chemicals, formaldehyde, **toluene** diisocyanate and trimellitic anhydride did not exceed Fed-OSHA and ACGIH permissible standards. However, formaldehyde concn ranged between 0.05 and 0.08 ppm. The reported symptoms were multiple, involving the eyes, nose, sinuses, throat, lungs, skeletomuscular system and central nervous system. Anti-formaldehyde, **toluene** diisocyanate, and trimellitic anhydride isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. The data suggest that a synergistic immunological response to airborne chemicals may be occurring in these subjects. In conclusion, immunological monitoring of affected individuals where chemicals are suspected may prove to be useful in future investigations of building related illness.

REVIEWED**

Mechanism of Action :

The in vivo exposure to an asthmogenic stimulus, **toluene** diisocyanate, causes airway epithelial damage associated with inflammation and increased bronchial hyperresponsiveness. The latter mechanisms might partly be mediated by the release of eicosanoids from bronchial epithelial cells. Previously it has been demonstrated that the in vitro exposure of bronchial epithelial cells to **toluene** diisocyanate results in the release of immunoreactive 15-hydroxyeicosatetraenoic acid, a product of activation of the 15-lipoxygenase pathway with inflammatory properties. Present study shows that **toluene** diisocyanate induced release of 15-hydroxyeicosatetraenoic acid from epithelial cells can be prevented by nedocromil sodium, an anti-asthmatic drug with anti-inflammatory properties. This mode of action of the compound may explain its clinical effectiveness in asthma.
[Mattoli S et al; Int Arch Allergy Appl Immunol 92 (1): 16-22 (1990)]**PEER REVIEWED**

Human Toxicity Excerpts :

Thirty factory workers whose annual exposure to **toluene** diisocyanate amounted to 280 hr were examined. Seven of them had been removed from their jobs for presenting respiratory symptomatology and a further five were removed for presenting bronchial asthma. Their medical histories were consulted and further measures were taken such as a radiological thorax study, total immunoglobulin-E, **toluene** diisocyanate, diphenylmethane diisocyanate and hexamethylene diisocyanate RAST, a basal spirometric study and finally a provocation test. The Rast proved negative in every case. In the spirometric study carried out on the provocation test, four cases showed a significant decrease in the forced expiratory volume in 1 second over 20% and over 40% in the FMEF and PEFR. There was no connection between the four patients who presented an elevated total immunoglobulin-E and the four who presented a positive provocation test. The provocation test proved negative in five of the seven patients removed from their places of work. Two of the four workers who responded positively to the provocation test remained in their places of work during the **toluene** diisocyanate foam test without showing any symptoms. The patients who presented symptoms did not appear to present bronchial obstruction during the provocation test. Nonetheless, patients who seemingly had not shown any symptoms presented what appeared to be bronchial obstruction.

Non-Human Toxicity Excerpts :

In dogs, a correlation has been made between immunological and respiratory responses to **toluene** diisocyanate. Dogs exposed once every second week for 41 wk to 1 mg/kg **toluene** diisocyanate delivered as an aerosol intratracheally developed a systemic immune response to **toluene** diisocyanate conjugated with dog serum albumin as well as immediate-type airway responses.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 307 (1986)]**PEER REVIEWED**

Human Toxicity Excerpts :

A series of workers with exposure to and respiratory symptoms from **toluene** diisocyanate was compared with a group of exposed, asymptomatic workers and with normal controls using immunologic and clinical evaluations. Improved understanding of **toluene** diisocyanate-induced respiratory disease may best be achieved by categorizing the symptomatic workers into at least 3 and possibly 4 groups: immunologic asthma; pre-existing chronic respiratory disease exacerbated or unaffected by **toluene** diisocyanate; asthma coincidental with exposure, and possibly respiratory disease secondary to toxic or inflammatory mechanisms.
[Patterson R et al; Int Arch Allergy Appl Immunol 84 (1): 93-100 (1987)]**PEER REVIEWED**

Sediment/Soil Concentrations :

Ten days after an accident resulting in the spillage of 13 tons of **toluene** diisocyanate from a lorry on a swampy wet forest area, **toluene** diisocyanate and toluenediamine were /found/ in the soil. After six yr, only **toluene** diisocyanate-derived polyureas were found in soil samples taken at the same site.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

Human Toxicity Excerpts :

The nature of neurohumoral regulation was studied in 125 healthy workers, aged 20-40 yr, with different length of service and **toluene** diisocyanate exposure levels. Adrenal gland activity and some haematological parameters were determined. Neurohumoral regulation of adaptation processes in **toluene** diisocyanate exposed persons seemed to display some cyclicity, somehow related to the length of service. Two early regulatory phases (service up to 3 yr) had common features unrelated to the exposure levels, while after 3 yr of employment some dissimilarities evolved which did depend on the **toluene** diisocyanate exposure levels.
[Ermakova GA, Kryzanovskaja NA; Gigiena truda i Professional'nye Zabolevanija (7): 22-35 (1988)]**PEER REVIEWED**

NIOSH Recommendations :

Experimental studies have demonstrated that **toluene** and TDA (a hydrolysis product of **toluene** diisocyanate) are carcinogens. The test results meet both OSHA and NIOSH criteria for classifying a substance as a potential occupational carcinogen. NIOSH therefore recommends that all isomers of **toluene** diisocyanate and TDA be considered as potential carcinogens and that exposures be limited to the lowest feasible concn.
[ANON; USDHHS, Public Health Service, Centers for Disease Control, NIOSH, Division of Standards Development and Technology Transfer, 4676 Columbia Parkway, Cincinnati OH 45226, USA, 1989. 20p. Bibl.]**PEER REVIEWED**

Sampling Procedures :

NIOSH Method: 5521. Analyte: 2,6-**Toluene** diisocyanate. Matrix: Air. Sampler: Impinger (solution of 1-(2-methoxyphenyl)-piperazine in **toluene**). Flow Rate: 1 l/min. Sample Size: 100 liters. Shipment: Ship in screw-cap vial refrigerated @ 4 deg C or lower. Sample Stability: May be unstable; perform steps 8 and 9 as soon as possible. /2,6-**Toluene** diisocyanate/
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 5521-1]**PEER REVIEWED**

Human Toxicity Excerpts :

Toluene diisocyanate is commonly used as the 2,4 and 2,6 isomers. NIOSH has estimated that 50,000 to 100,000 workers in the United States are regularly exposed to diisocyanates. As of 1977, 49,996 were estimated to be exposed to **toluene** diisocyanate alone. Methods for

measuring diisocyanate exposures were considered. The current American Conference of Governmental Industrial Hygienists' recommended standard is 0.005 ppm time weighted average and 0.02 ppm peak for four 15 min periods a day. Results of exposure measurements taken in industry were summarized. Health effects of diisocyanates were discussed. In laboratory animals, **toluene** diisocyanate has caused inflammation and necrosis when applied directly to the skin, conjunctivitis when applied to the eyes, and rhinitis, laryngitis, tracheitis, bronchitis, and pneumonia when inhaled. Diisocyanates are potent pulmonary sensitizers capable of causing isocyanate asthma in humans. They can induce nonspecific airways disease and hypersensitivity pneumonitis after either acute or chronic exposure.
[Musk AW et al; Am J Ind Med 13 (3): 331-49 (1988)]**PEER REVIEWED**

Human Toxicity Excerpts :

A 46 yr old man who had worked in a paint processing plast for over 29 yr was admitted to our hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonitis due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against **toluene** diisocyanate-human serum albumin and diphenylmethane diisocyanate-human serum albumin, precipitating antibody against **toluene** diisocyanate-human serum albumin, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coombs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggests the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.

Mechanism of Action :

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concn ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concn of tolyl group after 72 hr and persists at a nanomolar level even 2 wk following the exposure. The initial rate of (14)C uptake is also a linear function of the concn of **toluene** diisocyanate when expressed either as concn (ppm) or as concn multiplied by duration of exposure (ppm.hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm.hr. Finally, the inclusion of the data on

methyl isocyanate indicates that the uptake into arterial blood is a function of exposure concn, independent of isocyanate structure.

Environmental Abiotic Degradation :

Toluene diisocyanate reacts readily with compounds containing active hydrogens, such as water, acids, and alcohols(2). Contact with bases may cause uncontrollable polymerization with rapid evolution of heat(2). In concentrated solutions, hydrolysis of one of the isocyanate groups to the amine is followed by rapid reaction of the amine with an isocyanate group on another molecule leading to dimers, oligimers, and polymers(2). In one experiment the hydrolysis product yield was 20% diamine and 80% polyurea(3). When 50 ppm of **toluene** diisocyanate was added to model river and seawater systems, the concn fell to 0.1 ppm or less at the end of 1 day(1).

Environmental Biodegradation :

Toluene diisocyanates are expected to be hydrolyzed much more rapidly than they are attacked by microorganisms. The resulting **toluene** diamines are subject to a wide variety of biochemical transformations.
[ITC/USEPA; Information Review #231 (Draft) Toluene Diisocyanates p. 19 (1981)]**PEER REVIEWED**

Mechanism of Action :

The beta-adrenoceptors on intact peripheral blood lymphocytes were studied in 21 allergic asthmatics, 11 **toluene** diisocyanate asthmatics and 17 normal subjects with radioligand binding assay technique. The airway responsiveness to methacholine provocation test was determined. The results indicated that beta-adrenoceptor Bmax values in allergic and **toluene** diisocyanate asthmatics were reduced but the affinity between receptor and ligand was increased; there was a positive correlation between the values of Bmax and forced expiratory volume in 1 second%, V25/Pr in both asthmatic groups, a positive correlation between the values of Bmax and PC20

in allergic asthmatics. The beta-adrenoceptor responsiveness was remarkably reduced in allergic asthmatics.

Human Toxicity Excerpts :

The respiratory status of factory workers exposed continously to isocyanates over 10 years was studied. A total of 80 workers in two facilities that manufactured fixtures used in the interiors of cars were examined and underwent spirometry before and after work. Of these, 12 were comparisons not exposed to **toluene** diisocyanate. Subjects included those previously examined in 1971. Ventilatory capacity tests were performed inlcuding forced expiratory volume in 1 sec and forced vital capacity testing. Annual decrements were calculated. The mean average concentration of **toluene** diisocyanate was not more than 0.0033 ppm respectively. Subjects who had been studied previously had a mean forced vital capacity of 104.6% and a mean forced expiratory volume in 1 sec of 107% of predicted values. Three subjects with significant obstruction in the lung function tests were smokers. The comparisons in facility 1 had a significantly lower percentage of the predicted forced fital capacity and forced expiratory volume than the exposed population. Most of the data from 1971 for annual decrement calculations were not reliable. A 10% decrement in forced vital capacity and forced expiratory volume in 1 second was indicative of significant postshift decline and would indicate the presence of isocyanate asthma or hypersensitivity; no subject at either facility met the criteria.
[Gee JB; Morgan WKC; J Occup Med 27 (1): 15-8 (1985)]**PEER REVIEWED**

Human Toxicity Excerpts :

Amine induced asthma was studied in polyurethane foam workers. A total of 12 subjects, occupationally exposed to polyurethane foams, who complained of wheezing and breathlessness at work were tested. Subjects were given 20 to 2000 ug methacholine. Forced expiratory volume in 1 sec was measured. Subjects were challenged with 0.01 ppm **toluene** diisocyanate for 15 min in an atmosphere chamber. Forced expiratory volume in 1 sec was measured. Positive tests were considered as a 15% fall in forced expiratory volume in 1 sec. High sensitivity to methacholine was seen in ten subjects with a 15% fall in forced expiratory volume in 1 sec at <1000 ug; normal subjects responded at 2000 ug. All subjects reacted to **toluene** diisocyanate.
[Cardura F, Moscata G; Brit J Indus Med 41: 552-3 (1984)]**PEER REVIEWED**

Human Toxicity Excerpts :

Sensitized subjects may develop symptoms of asthma after exposure to isocyanates in their place of work. After challenge with isocyanates in the laboratory, sensitized subjects develop immediate, late and dual asthmatic reactions. **Toluene** diisocyanate might cause late asthmatic reactions and increase bronchial responsiveness by causing an acute inflammatory reaction in the airways, and that airway inflammation may be responsible for persistence of occupational asthma induced by isocyanates. To test these hypotheses, sensitized subjects were examined during asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. It was observed that late and dual, but not early, asthmatic reactions are associated with a transient

increase of bronchial responsiveness which is associated with an acute inflammatory reaction of the airways characterized by an increase of neutrophils followed by eosinophils, by an increase of leukotriene B4 and albumin in bronchoalveolar lavage fluid, and that all these effects are inhibited by steroids. Longitudinal studies suggest that the majority of subjects with occupational asthma continue to have persistent asthma months and yrs after the cessation of exposure, and the results of our studies combined with the results of studies performed by others suggest that the persistence of asthma may be related to the persistence of airway inflammation. [Fabbri LM et al; Eur Respir J (Suppl 13): 136-38 (1991)]**PEER REVIEWED**

Human Toxicity Excerpts :

Twelve subjects were studied with inhalation challenge testing to **toluene** diisocyanate because of suspected asthma based on a consistent clinical and occupational history. In seven cases, asthma was documented by a positive inhalation challenge to low levels of **toluene** diisocyanate. Six of the seven reactors had persistent respiratory symptoms and required daily treatment even though they had been removed from isocyanate exposure for intervals as long as 12 years (mean 4.5 years). These six reactors had either dual (four cases) or late bronchospasm (two cases) to less than 20 ppb and all had a positive methacholine or cold air challenge prior to study. The one reactor with a negative methacholine challenge had a positive (immediate) bronchospastic response to a challenge performed one week after removal from isocyanate exposure. Five workers had a negative challenge, two of whom had persistent respiratory symptoms and positive methacholine challenges at the time of inhalation testing. ... Respiratory symptoms may persist following long-term removal from occupational exposure to and are associated with nonspecific bronchial hyperreactivity. The sensitivity may also persist for a long time even in the absence of any additional occupational exposure. Long-term prospective studies of symptomatic isocyanate workers are needed to fully define the extent of this problem. [Moller DR et al; Chest 90 (4): 499 (1986)]**PEER REVIEWED**

Human Toxicity Excerpts :

Symptoms and lung function of workers exposed to isocyanates in polyurethane foam factories were studied. A group of 67 workers was examined for **toluene**-diisocyanate ... exposure. Measurements were made by samples obtained from subject carried pumps. Interviews were also conducted for information of symptoms involving the nose, eyes, upper airways, and lung. Another group of 56 nonexposed workers was determined by spirometry and nitrogen wash out prior to the work shift. The exposed workers were examined again immediately after work. The variables studied were forced expired vital capacity and forced expired volume in 1 second. ... The highest exposure group was foaming machine workers, with a day mean exposure of 0.023 mg/cu m. Nonsmokers showed an increased frequency of symptoms involving the nose, throat, and dyspnea. Smokers had no significant increase. Smokers of the exposed group reported coughing. Only smokers reported symptoms classified as chronic bronchitis, with frequency independent of exposure. Decreased forced expired vital capacity and forced expired volume were observed in the exposed group. This group also showed increased expired vital capacity.

Lung function impairment was restricted to smokers. Spirometric and nitrogen washout variables did not change significantly during the work shift. Decreasing spirometric values with increased exposure was seen in smokers. Conclusions indicate that mean exposure of 0.01 mg/cu m/day to isocyanates may give an increased frequency of symptoms in nonsmokers.

(1986)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Groups of 120 male and 120 female CD-1 mice, three to four weeks old, were exposed to 0, 0.05, or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production grade **toluene** diisocyanate (approx 80% 2,4 isomer & 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 104 wk. There was a significant reduction in body weight in the high-dose group /sex not stated/ and a significant increase in mortality in both high and low-dose females by the termination of the study. No such effect was seen in males. Neither the types of tumor observed nor their incidences were dose-related, and both corresponded to those seen in historical controls for this strain of mice. However, dose-related pathological changes were observed in the nasal cavity (chronic or necrotic rhinitis), together with changes in the lower respiratory tract (interstitial pneumonia, catarrhal bronchitis) in both groups.

Non-Human Toxicity Excerpts :

Groups of 126 male and 126 female Sprague Dawley CD rats, six to nine weeks old, were exposed to 0, 0.05 or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production-grade **toluene** diisocyanate (approx 80% 2,4 isomer and 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 108 wk or 110 wk. A significant reduction in weight gain was observed during the first 12 wk of the study among the high-dose animals of each sex, but body wt gain was similar in all groups thereafter. No significant difference in mortality between treated and control groups of either sex was reported. Tumor incidences and types were reported to be similar in control and treated groups.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 304 (1986)]**PEER REVIEWED**

NIOSH Recommendations :

Probable Routes of Human Exposure :

THE RESPIRATORY HEALTH OF 277 WORKERS IN A NEW **TOLUENE** DIISOCYANATE (TDI) MANUFACTURING PLANT WAS STUDIED PROSPECTIVELY DURING 5 YR OF EXPOSURE. PERSONAL TDI MONITORS WERE USED TO CONTINUOUSLY MEASURE PEAK & 8-HR TIME-WEIGHTED AVG (TWA) CONCN IN MORE THAN 2000 SAMPLES. REGRESSION OF ANNUAL CHANGE ON SMOKING (PACK-YEARS), ATOPIC STATUS & CUMULATIVE TDI EXPOSURE, DICHOTOMIZED AT 68.2 PPB MONTHS INTO LOW & HIGH EXPOSURE GROUPS, SHOWED SIGNIFICANT EFFECTS OF SMOKING ON SPIROMETRIC TESTS & LUNG VOLUMES. AFTER ADJUSTING FOR PACK-YEARS OF SMOKING, THE 74 MEN IN THE HIGH CUMULATIVE TDI EXPOSURE CATEGORY HAD SIGNIFICANTLY LARGER DECLINE IN FEV1 (1-S FORCED EXPIRATORY VOLUME), % FEV (% FORCED EXPIRATORY VOLUME) & FEF25-75% (FORCED EXPIRATORY FRACTION FROM 25 TO 75% VITAL CAPACITY) THAN DID THE 149 MEN IN THE LOW CATEGORY. ANNUAL CHANGE IN FEV1 WAS THEN EXAMINED IN 6 SMOKING-EXPOSURE CATEGORIES: IN NEVER-SMOKERS, AVG ANNUAL DECLINE WAS 38 ML/YR GREATER IN THOSE WITH HIGHER CUMULATIVE TDI EXPOSURE.

Human Toxicity Excerpts :

A shortened protocol was developed for the epidemiological measurement of bronchial responsiveness to methacholine without compromising sensitivity, power, precision or safety, and without distorting the numerical value of the PD20.FEV1 (the cumulative dose from a doubling incremental sequence which provokes a 20% decrement in forced expiratory volume in 1 second). It was used in a survey of 254 polyurethane workers (83% of the eligible workforce) exposed occupationally to **toluene** diisocyanate. The mean duration of each test proved to be 38 min, it was well tolerated and 64 workers (25%) proved to be reactors. PD20.FEV1 appeared to be distributed unimodally. It was significantly correlated with questionnaire records of shortness of breath, chest tightness, and wheeze; and with pre-shift forced expiratory volume in 1 second and FEF25-75. Even the reactors requiring the highest dose of 640 cumulative inhalation units (1 unit = one 8.9 ul inhalation of methacholine 1 mg/ml) to generate a PD20 measurement reported significantly more wheeze than the non-reactors. This indicates that the test had clinical meaning throughout its dose range of 0.3-640 units. No correlation was found between PD20 and individual changes in ventilatory function across the working shift, but mean shift changes were negligible and not statistically significant. PD20 was also found to be unrelated to age, sex, race, smoking, cough and atopy.

Artificial Pollution Sources :

Levels of 100-17,700 ug/cu m **toluene** diisocyanate were reported in samples from the stack exhaust of a polyurethane foam production plant.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

Mechanism of Action :

Serum immunoglobulin-G and immunoglobulin-E to isocyanate haptenized human serum albumin (HSA) were estimated by ELISA in 55 isocyanate workers who underwent isocyanate inhalation challenge studies in Montreal, Canada. The challenges were negative in 29 workers and positive in 26 workers. Isocyanate antibodies were estimated by ELISA index. The mean immunoglobulin-G indices were found to be significantly higher in the challenge-positive workers, and there was a similar trend for the immunoglobulin-E indices. Antibody specificities for **toluene** diisocyanate-human serum albumin, diphenylmethane diisocyanate-human serum albumin, and hexamethylene diisocyanate-human serum albumin were determined by inhibition studies with a variety of isocyanate haptenized carriers. The other isocyanate substituted carriers were either noninhibitory or caused only partial inhibition as contrasted with the complete inhibition achieved by human serum albumin conjugated to the isocyanate to which the worker was exposed. We interpret these specificity studies as indicating that the inhalation of isocyanates results in production of antibody that recognizes new antigenic determinants that develop from the coupling of isocyanates to homologous proteins.
[Grammer LC et al; J Allergy Clin Immunol 86 (1): 94-8 (1990)]**PEER REVIEWED**

Human Toxicity Excerpts :

Subjects exposed to 0.0010 to 0.0015 ppm of **toluene** diisocyanate demonstrated a normal age and smoking-related rate of decline in forced expiratory volume in 1 second and no evidence that it was related to isocyanate exposures.

Human Toxicity Excerpts :

Respiratory variables were measured in workers exposed to **toluene** diisocyanate in Canada. Exposure and effect relationships were studied. Results from 95 isocyanate workers were compared with unexposed workers. Exposed workers were grouped according to production areas based on isocyanate concentrations measured. Individual monitors were worn to identify exposure for some workers. Symptoms and history of respiratory illness were compared through questionnaires. Pulmonary function tests included forced vital capacity, forced expiratory volume in 1 second, and forced expiratory flow at 50% and 75% of vital capacity. Pulmonary function was measured at the beginning and end of work shifts on Monday, Wednesday, and Friday of a work week. Regression analysis of exposure concentration and other variables was attempted. When comparisons were adjusted for smoking habits, exposed workers had a significantly lower family history of respiratory complaints. Isocyanate workers had slightly lower base line lung function than comparisons, but had significantly higher declines in pulmonary function over the work week. A 5% or greater decline over a day occurred in 44 percent of exposed but only 22% of comparison workers. Foam line and finishing area workers had greatest declines in forced vital capacity and forced expiratory volume in 1 second. It was concluded that although regression analysis does not show an exposure/effect relationship, an all or none effect may be operating with acute and chronic compartments. However, sample size may have been insufficient.
[Holness DL et al; J Occup Med 26 (6): 449-55 (1984)]**PEER REVIEWED**

Human Toxicity Excerpts :

... The toxicity of inhaled vapors of diisocyanates is summarized. Humans are exposed to high concentrations of diisocyanates in polyurethane industries. Toxic symptoms are acute inflammation with lachrymation, rhinitis, soreness and burning in the throat and upper part of the chest, and coughing. Fire fighters are particularly prone to these clinical symptoms. The toxic limit value for **toluene** diisocyanate is 0.005 ppm. Exposure to diisocyanates can cause asthma.

Environmental Fate :

TERRESTRIAL FATE: Ten days after a spill of 13 tons of **toluene** diisocyanate (TDI) onto swampy, wet forest soil, TDI and toluenediamines were found in the soil(1,2). The TDI solidified and the area was covered with sand. The soil concn of TDI and toluenediamine combined declined from the parts per thousand to parts per million range between 10 days and 12 wk after the spill(2). No TDI was detected in a connecting brook 10 days after the spill(2). After 6 years only TDI-derived polyureas were found at the site(1). In a simulated spill, 5 kg of TDI in a container was covered with 50 kg of sand and 5 kg of water at ambient temperatures and samples taken from the top and bottom of the sand pile. After 24 hr, 5.5% of the TDI remained unreacted and after 8 days 3.5% remained(2). The reaction product was largely polyureas(2).

Patients (3) with history of recurrent **toluene** abuse were hospitalized and severe metabolic acidosis, electrolyte abnormalities, hypoalkemia, and muscular weakness were present. Distal renal tubular acidosis was believed to be present in 2/3 patients.

[Fiscman CM, Oster JR; Am Med Assoc 241 (16): 1713-15 (1979) as cited in NRC; Alkyl Benzenes p.284 (1981)]**PEER REVIEWED**

Child of a mother with a 14 year history of solvent abuse showed symptoms of fetal alcohol syndrome.
[Toutant C, Lippman S; Lancet 1 (8130): 1356 (1979)]**PEER REVIEWED**

A 27-year-old male developed cerebral and cerebellar atrophy over a period of five years of extensive glue sniffing. He also developed bilateral optic atrophy with blindness and severe sensorineural hearing loss.
[Ehyai A, Freemon FR; J Neural Neurosurg Psychiatry 46 (4): 349-51 (1983)]**PEER REVIEWED**

Toluene appears to produce reversible effects upon liver, renal, and nervous systems. ... The nervous system appears to be the most sensitive to the effects of **toluene**. ... High level **toluene** exposures produced incoordination, ataxia, unconsciousness and eventually, death. Lower level acute exposures in man produce dizziness, exhilaration and confusion. Activity level has been inadequately studied. Schedule controlled behaviors have been reported to produce inverted U-shaped concentration-effect curves on response rate measures. Alterations at levels as low as 150 ppm have been reported when appetitive contingencies are used. Very few studies of the nervous system have been performed at levels below 1000 ppm and most of the results were inconclusive. ...

IN EXPERIMENTS IN VITRO, **TOLUENE** DID NOT CHANGE NUMBER OF SISTER-CHROMATID EXCHANGES OR THE NUMBER OF CHROMOSOMAL ABERRATIONS IN HUMAN LYMPHOCYTES.
[GERNER-SCMIDT P, FRIEDRICH U; MUTATION RESEARCH 58: 313 (1978)]**PEER REVIEWED**

A 28 yr old painter who was believed to be a habitual **toluene** sniffer was admitted to Chiba Emergency Medical Center on several occasions. Symptoms included: Tremors of the upper extremeties, staggering of gait, slurred speech, slight mental deterioration, pendular nystagmus, bradycardia, mild tremor of the leg, action myoclonus, and head and trunchal titubation. There was no dysmetria. The involuntary movements were classified as hyperkinesie volitionnelle. Muscle tone was hypotonic. Muscle weakness and atrophy were not seen. Deep tendon reflexes were all exaggerated, but there was no pathological reflex. He showed wide-based ataxic gait. Sensory and autonomic functions were normal. Blood, urine and cerebrospinal fluid analysis appeared normal. Electroencephalography showed 40-50 uV, 9-10 c/s alpha waves with a few fast waves. Brain CT scan revealed a moderate enlargement of the lateral and third ventricles. Surface electromyography was performed on the proximal musculature of the arm. 3 c/s reciprocal rhythmical grouping discharges were found at the terminal phase of the elbow bending. The tremor was diminished by 20 minutes ischemic compression test of the arm. With respect to therapy, clonazepam was useful for hyperkinesie volitionnelle. He became able to drink a cup of water without spilling it by his own hands, and was discharged from hospital on April 3rd, 1981. It was believed that he was a habitual sniffer to **toluene**. On June 30th, 1983 he was found comatose. On admission to Chiba

Emergency Medical Center, his breath smelt of **toluene**. His blood **toluene** level was 7.53 ppm, and urinary hippuric acid concentration was 9,500 mg/l. He died on July 9th, 1983, because of disseminated intravascular coagulation, multiple organ failure and perforation of the terminal ileum. Autopsy was performed and neuropathological findings were as follows. 1) Diffuse demyelination and gliosis of the cerebral and cerebella white matter. 2) Marked loss of Purkinje cells of the cerebellum. 3) Astrocytic proliferation of the dentate fugal system and inferior olivary nucleus of medulla. ...
[Arai K et al; Brain Nerve Tokyo 38 (12): 1181-86 (1986)]**PEER REVIEWED**

Autopsy findings on a man who fell from a height due to acute **toluene** poisoning while painting are described. Gas chromatographic examination revealed that the **toluene** concentrations of his blood, lung, liver and brain were 48, 35, 65 and 80 ug/g, respectively. These **toluene** levels were not enough to be definitely lethal, but were enough to anesthetize the central nervous system.
[Takeichi S et al; Forensic Sci Int 32 (2): 109-16 (1986)]**PEER REVIEWED**

The psychological performance of 43 rotogravure printers exposed to a mean time- weighted average of 117 ppm **toluene** for a mean time period of 21.7 yr was compared to that of 31 offset printers with a mean working period of 23 yr. The offset printers were exposed to mixtures of aliphatic hydrocarbons or ethyl acetate (amounts not given) for a total of 10 to 60 min daily. Drinking habits were considered in grouping the workers. The test battery consisted of standardized tests for verbal and visual cognition and memory, perceptual motor speed, and psychomotor abilities. Performances of the two printer groups were similar with rotogravure printers having statistically significant lower scores on tests measuring visual cognitive abilities. Mean test performances indicated that drinking habits did not explain the impairment of visual cognitive abilities.
[Hanninen H et al; Int Arch Occupat Environ Health 59 (5): 475-83 (1987)]**PEER REVIEWED**

Acute poisoning may result from exposure to high concn of **toluene**; A /CNS depressant/ effect is produced. Human death has resulted from exposure to 10,000 ppm. **Toluene** is more acutely toxic than benzene; however, severe blood disorders of the type associated with benzene are not reported. Inhalation of 200 ppm has affected the CNS in humans.
[Cleland, J.G., G.L. Kingsbury. Multimedia Environmental Goals for Environmental Assessment. Volume 1. EPA-600/7-77-136a. Research Triangle Park, NC: EPA, Nov. 1977.,p. E-146]**PEER REVIEWED**

Vapors irritate eyes and upper respiratory tract; Cause dizziness, headache, anesthesia, and respiratory arrest. Liquid irritates eyes. If aspirated, causes coughing, gagging, distress, and rapidly developing pulmonary edema. If ingested causes vomiting, griping, diarrhea, and depressed respiration. Kidney and liver damage may follow ingestion.
[U.S. Coast Guard, Department of Transportation. CHRIS - Hazardous Chemical Data. Volume II. Washington, D.C.: U.S. Government Printing Office, 1984-5.]**PEER REVIEWED**

In recent years some youngsters have been indulging in what is called thinner inhalation, posing a serious social problem. Organic solvents have also been widely used industrially as adhesives or degreasing and rinsing agents, generating a kind of occupational disease which has become a medical problem. Some

school children who refuse to go to school complaining of headache, head heaviness, blurred vision, diplopia, or dizziness, may actually have **toluene** toxicosis caused by the adhesive they use in constructing plastic models. /An examination of/ 35 such patients neurogically, found some impairment in the cerebellar cortex, cerebellar nuclei, or efferent pathways. This report is presented to invite comments from other researchers.
[Sakata E et al; Pract Otal Kyoto 79 (12): 1999-2013 (1986)]**PEER REVIEWED**

Severe, acute **toluene** intoxication in two workers was described. Special attention was paid to the metabolism of **toluene** in man and to the choice of reference parameters to monitor intoxication. The men had tiled a small swimming pool to be used for exercise programs in a rehabilitation clinic. They had used a special glue to make the joints of cement between the tiles resistant to bleaching solution; the next day they removed the excess glue using **toluene**. One worker was exposed for 2 hours and the other for 3 hours. Both were overcome with the fumes, and were found lying at the bottom of the pool. Symptoms included stupefaction, paresis, and amnesia. Patient-A had mucosal irritation of the eyes and slurred speech. He was stuporose and unable to walk or sit. His amnesia lasted for about 3 hours. Patient-B had mucosal irritation of the eyes, was drowsy, and was just able to walk. He had normal speech and complained of headache. The duration of his amnesia was about 2.5 hours. Solid evidence for **toluene** exposure was provided by the blood **toluene** concentration. The concentration 2 hours after exposure was 4.1 mg/l in patient-A and 2.2 mg/l in patient-B.
[Meulenbelt J et al; Br J Ind Med 47 (6): 417-20 (1990)]**PEER REVIEWED**

The memory sequelae for a group of female workers accidentally exposed to organic solvents were examined retrospectively to evaluate complaints of residual memory impairment. The subjects included seven employees (mean age 32.1 years) who agreed to retesting and who had been severely intoxicated by exposure to **toluene** and aliphatic hydrocarbons found in adhesives used in the manufacture of tennis balls. They were compared to eight workers (mean age 33.7 years) who were solvent exposed but not affected by the accident and ten workers (mean age 36.6 years) who had no exposure. Acute symptoms included faintness, nausea, vomiting, and headache. Complaints of impaired memory, personality changes, and loss of confidence persisted 8 months after exposure. Memory testing was first performed 2 months after exposure, with the follow up 6 months later to assess recovery. The three memory tasks included paired associate task, serial position task, and Brown-Peterson task. The subjects showed normal patterns of performance on tests of learning and short term and long term memory, but demonstrated marked difficulties when attention had to be divided between two resource competing tasks. The clearest evidence of impairment was observed in the Brown-Peterson task, where the acute group showed a significantly greater increase in word recall omission after periods of counting backwards in threes. The magnitude of the memory sequelae was not correlated with scores of self rated depression. It was concluded that solvent intoxication can cause neuropsychological sequelae lasting more than 8 months; memory tasks could prove useful in identifying memory impairment in other occupationally exposed groups.
[Stollery BT, Flindt MLH; Scand J Work, Environ, Health 14 (1): 45-8 (1988)]**PEER REVIEWED**

In a cross-sectional study of 181 male workers of a rotogravure printing plant, most of whom were exposed to **toluene** levels well above the GDR threshold limit values, 55 subjects revealed pathological liver screening values (activities of serum aspartate aminotransferase, alanine aminotransferase, gamma

glutamyltransferase; liver size). The differential diagnostic examination showed in 51 of these 55 subjects an association with competing factors such as alcohol abuse (78%) and overweight (40%), to a slight extent disorders of fat and carbohydrate metabolism and of the gallbladder. Drug intake did not play any role. The variance and regression analyses of the biochemical data have shown that alcohol significantly and considerably increases the activities of all three enzymes tested. Bodyweight had a similar, but less pronounced, significant effect. On the other hand, in subjects with a higher alcohol intake the activities of liver enzymes in highly **toluene** exposed subgroups were significantly and clearly lower than among slightly **toluene** exposed workers.
[Boewer C et al; Int Arch Occup Environ Health 60 (3): 181-6 (1988)]**PEER REVIEWED**

General health effects include lethality, growth, morbidity, liver and kidney damage and miscellaneous effects. Neurobehavioral effects include epidemiological and clinical findings, activity and sleep, performance and learning, electrophysiological effects. Evaluation and synthesis of data is included. It was concluded that low level exposure to **toluene** has its primary effect on the CNS. From a systematic or general point of view it is not clear what this effect is. Both depressant and excitatory effects (possibly concentration dependent) were reported as well as other kinds of results. Other health effects were not life threatening at any exposure level short of that producing lethality. Effects were reversible even at extremely high exposure levels for very long durations.
[Benignus VA; Neurotoxicol 2 (3): 567-88 (1981)]**PEER REVIEWED**

Toluene embryopathy is characterized by microcephaly, central nervous system dysfunction, attentional deficits and hyperactivity, developmental delay with greater language deficits, minor craniofacial and limb anomalies, and variable growth deficiency. Previously, three affected children, born to women who inhaled **toluene** regularly throughout pregnancy, have been reported. Two more cases are described emphasizing the importance of **toluene** as a potential human teratogen.
[Hersh JH; J Med Genet 26 (5): 333-7 (1989)]**PEER REVIEWED**

Neurobehavioral tests were undertaken by 30 female workers exposed to **toluene** and matched controls with low occupational exposure to **toluene**. The environmental air levels (TWA) of **toluene** was 88 ppm for the exposed workers and 13 ppm for the controls. The **toluene** in blood concentrations for the exposed workers was 1.25 mg/l and for the controls 0.16 mg/l. Statistically significant differences between workers exposed to **toluene** and controls in neurobehavioral tests measuring manual dexterity (grooved peg board), a visual scanning (trail making, visual reproduction, Benton visual retention, and digit symbol), and verbal memory (digit span) were observed. Further, the performance at each of these tests was related to time weighted average exposure concentrations of air **toluene**. The workers exposed to **toluene** had no clinical symptoms or signs. The question arises as to whether these impairments in neurobehavioral tests are reversible or whether they could be a forerunner of more severe damage.
[Foo SC et al; BR J Ind Med 47 (7): 480-4 (1990)]**PEER REVIEWED**

When compared with benzene, **toluene** has little to no effect on immunocompetence. However, it should be noted that **toluene** exposure effectively attenuates the immunotoxic effects of benzene (probably because of competition for metabolic enzymes).
[Klaassen, C.D., M.O. Amdur, Doull J. (eds.). Casarett and Doull's Toxicology. The Basic Science of Poisons. 5th ed. New York, NY: McGraw-Hill, 1995. 380]**PEER REVIEWED**

Neutral organic solvents such as ... **toluene** ... cause pain on contacting the eye, and examination after a generous splash of solvent shows dulling of the cornea. The epithelium will show punctate staining with fluorescein. The damage appears to be scattered loss of epithelial cells due to solution of some of the fats that occur in these cells.

The following Overview, *** **TOLUENE** ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- ACUTE INGESTION -
  1. Causes CNS depression, oropharyngeal and gastric pain, vomiting.
- ACUTE INHALATION -
  1. Causes CNS excitation followed by CNS depression and nausea. Ataxia, fatigue, seizures and general anesthesia occur at high concentrations.
- CHRONIC INHALATION -
  1. SYNDROMES - Muscular weakness, gastroenteritis, renal tubular acidosis, and neuropsychiatric syndrome are common in **toluene** sniffers.
  2. EFFECTS - may include hypokalemia, hematuria, proteinuria, oliguria, paresis, rhabdomyolysis, hallucinations, hyperactive reflexes, peripheral neuropathy, personality changes, tremors, headaches, emotional lability, memory loss.
  3. SEQUELAE - Progressive, irreversible encephalopathy with cognitive difficulty and cerebellar ataxia, and organic affective syndromes have been described.
- EYE EXPOSURE -
  1. Blepharospasm, conjunctivitis, corneal edema, and corneal abrasions usually resolve over 1-2 days.
- DERMAL EXPOSURE -
  1. Prolonged or repeated dermal exposure to the liquid may defat the skin.

VITAL SIGNS

0.2.3.1 ACUTE EXPOSURE

- Bradycardia, hypotension and hypoventilation are rare effects.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Eye exposure causes irritation and superficial injury. Chronic abuse associated with decreased visual acuity, impaired color vision, optic atrophy, and ototoxicity.

CARDIOVASCULAR

0.2.5.1 ACUTE EXPOSURE

- ACUTE INHALATION - may cause dysrhythmias (usually in chronic abusers). Bradycardia, ventricular fibrillation, and myocardial infarction have been reported.
- CHRONIC INHALATION - Chronic sniffers may develop dysrhythmias, including PVCs and supraventricular tachycardia; dilated cardiomyopathy has been reported.
- ACUTE INGESTION may cause tachycardia and hypertension.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Inhalation may cause irritation, acute bronchitis, bronchospasm, pulmonary edema, pneumonitis, and asphyxia. Chronic abusers may develop respiratory failure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- ACUTE INGESTION - **Toluene** ingestion causes CNS depression.
- ACUTE INHALATION - 400 to 800 ppm: Euphoria, giddiness, tremors, nervousness, insomnia, headache, dizziness, fatigue, drowsiness, confusion, vertigo, increased reaction time; 800 ppm: ataxia, fatigue, seizures. 10,000 ppm: general anesthesia.
- CHRONIC INHALATION may cause hyperactive reflexes, peripheral neuropathy, personality changes, tremors, headaches, emotional lability, cognitive dysfunction, memory loss.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Ingestion or inhalation may cause vomiting, abdominal cramps, and diarrhea.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Rarely hepatorenal failure has been attributed to **toluene** abuse or occupational exposure. Hepatomegaly and impaired liver function has also been reported.

GENITOURINARY

0.2.10.1 ACUTE EXPOSURE

- Transient distal renal tubular acidosis (RTA), with

hyperchloremic metabolic acidosis, hypokalemia, and urine pH >5.5, is common in hospitalized paint sniffers. negative.
- Proximal RTA or Fanconi's syndrome is less common (urine pH >5.5, uricosuria, hypophosphatemia, hypocalcemia).
- Isolated cases of irreversible renal insufficiency, glomerulonephritis, focal segmental glomerulosclerosis, acute interstitial nephritis, and renal failure secondary to myoglobinuria have been reported.

ACID-BASE

0.2.11.1 ACUTE EXPOSURE

- Hyperchloremic metabolic acidosis common in hospitalized **toluene** abusers.

FLUID-ELECTROLYTE

0.2.12.1 ACUTE EXPOSURE

- Hypokalemia, metabolic acidosis, and hypophosphatemia are typical; hypercalcemia and hypouricemia less frequent. Hypocalcemia and precipitation of tetany has occurred during correction of acidemia.
- Patients with weakness may have severe fluid/electrolyte imbalance.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Prolonged contact may cause drying and defatting or superficial burns.

MUSCULOSKELETAL

0.2.15.1 ACUTE EXPOSURE

- Rhabdomyolysis is common in chronic **toluene** abusers. Severe muscle weakness is a common presentation in chronic abuse.

PSYCHIATRIC

0.2.18.1 ACUTE EXPOSURE

- Psychiatric disorders are common in chronic **toluene** abusers; including bizarre behavior, acute paranoid psychosis, confusion, visual and auditory hallucinations, mood lability, and decreased IQ.

REPRODUCTIVE HAZARDS

- Multiple physical deformities, with signs similar to fetal alcohol syndrome, microencephaly, CNS dysfunction, and variable growth deficiencies have occurred in infants born to mothers who abused **toluene** during pregnancy.

GENOTOXICITY

- There is conflicting information in the literature regarding the potential of **toluene** to cause DNA strand

breaks. **Toluene** was not mutagenic in the Ames assay. Chromosome damage has been reported.

Laboratory:

- **Toluene** may be measured in the breath and blood; hippuric acid and cresol metabolites may be measured in the urine.
- Obtain a baseline CBC and monitor renal and hepatic function tests, urinalysis (including urine pH) electrolytes, and CPK. Monitor arterial blood gases in symptomatic patients.

Treatment Overview:

ORAL EXPOSURE

- EMESIS - Emesis is probably not indicated due to the possibility for aspiration of gastric contents.
- GASTRIC LAVAGE may be indicated when the patient has ingested a large quantity of **toluene**, or there is a large amount of benzene contamination, and emesis is contraindicated (obtunded, comatose, convulsing). The potential toxicity of the amount ingested must be weighed against the substantial risk of aspiration.

1. GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.

a. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.

- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with intravenous potassium.
- MONITOR PATIENT for RESPIRATORY DISTRESS.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.
- CHRONIC EXPOSURE - Evaluate renal and liver function.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor

for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with potassium. CAUTION - Hypocalcemia may ensue following fluid and electrolyte replenishment.
- MONITOR for RESPIRATORY DISTRESS, assure airway patency and adequacy of ventilation and oxygenation.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.

EYE EXPOSURE
- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE
- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Ingestion - 60 mL lethal in an adult. Inhalation - 600 to 800 ppm for 3 hrs caused fatigue, nausea, confusion, ataxia; 10,000 ppm causes general anesthesia.

... Groups of rats were trained on the conditioned avoidance response task during the last week of a 5 week exposure to 1400 or 1200 ppm **toluene** (14 hr/day, 7 days/week) or during the first or third weeks after the exposure ended. None of the three groups ... were able to acquire the auditory condition avoidance response ... . Subsequent tests ... revealed that hearing with these rats was unimpaired at 4 KHz, slightly impaired at 8 KHz, and markedly impaired at 12 KHz and above.
[Pryor GT et al; Neurobehav Toxicol Terat 5 (1): 53-7 (1983)]**PEER REVIEWED**

Pregnant CD-1 mice were housed singly in multicompartment cages in inhalation chambers and exposed to **toluene** at a concentration of 0, 750, or 1500 mg/cu m (0, 200, or 400 ppm) for 7 hrs/day from day 7 through day 16 of gestation. The mice were killed on day 17 of gestation and the fetuses were removed and examined. Maternal weight gain was not affected by **toluene** exposure but the liver to body weight ratio was significantly reduced. The treated dams showed no significant differences in the average

number of implantation sites, number of live fetuses, fetal mortality, or fetal body weight at either **toluene** concentration compared to control values. The incidence of enlarged renal pelvis was significantly greater in fetuses exposed to 200 ppm than in the fetuses exposed to 400 ppm or in the controls. A shift in rib profile (number of fetuses with 13 ribs) was observed in the higher **toluene** concentration group, and this shift was significantly different from the rib profile of controls. There was an increase in the total activity of lactic dehydrogenase activity in the brain of the dams from the 400 ppm group. The total activity of lactic dehydrogenase in the **toluene** exposed pups did not differ significantly from the controls for liver, heart, lung, or kidney, but the brain lactic dehydrogenase activity of the treated group was slightly greater than the control value.
[Courtney KD et al; Fundam Appl Toxicol 6: 145-54 (1986)]**PEER REVIEWED**

Behavioral toxicity of **toluene** was assessed in mice confined in a 20 liter hermetically sealed chamber for several hours. **Toluene** was introduced through a port and volatilized by a hot plate. Samples of chamber air for analysis were taken through another port. A smaller mesh cage held the mouse within the larger chamber. Schedule-controlled responding was developed by arranging that a response, breaking a beam of light, was followed by mild (under an F1 60 sec) schedule. Responding was much more rapid in the presence of stimuli correlated with the F1 schedule than when the schedule was not operating. Standard sessions consisted of alternating series of 8 consecutive F1 60 sec and inter-series 30 min time-outs. Concentration-effect curves were determined by exposing a mouse to incremental additions of **toluene** at 30 min intervals. **Toluene** increased the rate of responding in most mice at levels of about 700 ppm. Higher concentrations progressively reduced responding. The ED50 (the concentration reducing responding by 50%) averaged 1657 ppm in 10 mice. It is estimated that there is a 1/1000 chance /ED001/ of the responding of a mouse being reduced by as much as 10% by a concentration of **toluene** of 69 ppm.
[Glowa JR et al; J Environ Pathol Toxicol Oncol 6 (5-6): 153-68 (1986)]**PEER REVIEWED**

Sixteen rats were chronically implanted with bipolar electrodes in the hipocampal regions containing cells generating electric theta-activity. The animals were divided into 4 groups of which 2 were exposed to 500 ppm of **toluene** in inhalation chambers, for 8 or 16 hours per day for 5 days per week in 12 weeks respectively, and 2 served as controls. The hippocampal electric activity was recorded 48 hours after each weekly exposure. Frequencies of theta-activity in the exposed groups were found to differ from their respective control group by variance analysis. Each point on the frequency versus time plot were further analysed by Student's t-test. Compared to the non-exposed group the eight hours daily exposed showed an initial period of increased frequency of the regular theta-waves together with an increased incidence of theta-activity after 1-2 weeks of exposure. In the sixteen hours daily exposed rats two weeks of **toluene** inhalation produced a significant reduction in the theta-wave frequency. This change was also reached after either weeks of exposure in the eight hours daily exposed group. At this moment the theta-activity was frequency disrupted by short amplitude irregular waves, a phenomen which increased gradually throughout the rest of the exposure period. The average blood concentration of **toluene** was 16.7 ug/ml and 17.7 ug/ml and not significantly different for the eight and sixteen hours exposed groups respectively.
[Naalsund LU; Acta Pharmacol Toxicol 59 (4): 325-31 (1988)]**PEER REVIEWED**

The effects of **toluene** vapors on brain lipid changes were investigated in male Sprague-Dawley rats. The animals (8/group) were continuously exposed to 320 ppm **toluene** for 30 days. Controls were exposed to

air. Exposed animals showed decreased body weight ($p< 0.01$), decreased brain weight ($p< 0.01$), and a decrease in the weight of the cerebral cortex ($p< 0.05$) when compared to controls. In the cerebral cortex of exposed rats, total phospholipids was reduced ($p< 0.001$), there was an increase in phosphatidic acid ($p< 0.05$) and a decrease in a minor fatty acid of ethanolamine phosphoglyceride ($p< 0.05$). No changes in lipids were found in the brain stem.
[Kyrklund T et al; Toxicology 45: 123-33 (1987)]**PEER REVIEWED**

With the intention of investigating possible morphological alterations effected by **toluene** in the developing CNS, rat pups were exposed to 100 ppm and 500 ppm of atmospheric **toluene** from postnatal day 1 until sacrifice at postnatal day 28, when the hippocampal region (area dentata, Ammon's horn, subiculum) was examined by light microscope and alterations in the volumes of the layers of the subdivisions were determined. The layers of Ammon's horn and the subiculum were not affected qualitatively or quantitatively by the 500 ppm exposure. Within the area dentata, the volume of the granule cell layer was 6% smaller in animals exposed to 100 ppm and 13% smaller in animals exposed to 500 ppm than they were in controls. The volumes of the hilus, which is a terminal field of granule cell axons, and the commissural-association zone of the dentate molecular layer, which is the terminal field of the hilar projection to the granule cells, were smaller (12% and 19%) in animals exposed to 500 ppm than they were in controls. Argyrophilic cells were found in the granule cell layer of all animals exposed to 500 ppm. Pronounced granule cell degeneration was found in one animal exposed to 500 ppm. The granule cell layer of animals exposed to 100 ppm appeared qualitatively normal. The alterations reported here support the few earlier reports of morphological alterations in the CNS of adult laboratory animals. Effects of **toluene** similar to those described, that is alterations in specific neuron populations and their afferent and efferent terminal fields may complement changes in neurophysiology and behavior that have been observed in prenatally and perinatally exposed rodent pups. Causal relationships, however, remain to be elucidated.
[Slomianka L et al; Toxicol 62 (2): 189-202 (1990)]**PEER REVIEWED**

The aim of the present study was to investigate the effects of **toluene** on fetal development in well nourished and malnourished rats. Long-term behavioral consequences after in utero exposure were also studied. **Toluene** (1.2 g/kg sc) was administered daily to well nourished and to malnourished (food restricted to 50% of ad libitum intake) pregnant rats, during the second (8-15 days) or the third week of pregnancy (14-20 days). Offspring were evaluated for malformation, development of the skeleton, prenatal growth of the brain and liver, postnatal growth and long lasting behavioral effects. In utero exposure to **toluene** during the third week of pregnancy resulted in low body weight at birth, which persisted in the male offspring into adulthood. Malnutrition increased fetal susceptibility to the effects of **toluene** as indicated by evaluation of the development of the skeleton. Behavioral tests performed when the pups were 30 and 90 days old showed effects of in utero malnutrition (increased ambulation and worse performance in a shuttle box), but no behavioral effects related to **toluene** exposure were detected. These data indicate that in utero exposure to **toluene** can have long lasting effects on body growth and that maternal malnutrition increases the risk for **toluene** fetotoxicity.
[Silva V AD et al; Toxicol 64 (2): 155-68 (1990)]**PEER REVIEWED**

Toluene did not induce gene mutations in Salmonella typhimiurium strain TA98, TA100, TA1535, or TA1537 with or without exogenous metabolic activation. In the mouse lymphoma assay, **toluene** gave an equivocal response with and without exogenous metabolic activation. **Toluene** did not induce sister chromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of exogenous metabolic activation.

[DHHS/NTP; Toxicology and Carcinogenesis Studies of Chlorobenzene in F344/N Rats and B6C3F1 Mice (Inihalation Studies) p.4 (1990) Technical Rpt Series No. 371 NIH Pub No. 90-2826]**PEER REVIEWED**

... **Toluene** can alter learned behavior at concentrations below anesthetic levels but, in general, above 1000 ppm.

Toluene was reported to induce chromosomal aberrations in the bone marrow cells of male albino rats after chronic inhalation exposure to 5.4 or 50.7 mg/cu m on 4 hr/day, five days/wk for four months or after sc injection of 0.8 g/kg bw. Chromosomal aberrations in bone marrow cells were reported following sc injection of 1 g/kg bw daily for 12 days to male albino rats.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 98 (1989)]**PEER REVIEWED**

Toluene and benzene administered concurrently were reported to have an additive effect on induction of chromosomal aberrations. **Toluene** reduced the number of sister chromatid exchanges induced by benzene when both compounds were administered intraperitoneally to DBA/2 mice and reduced the clastogenic activity of benzene when the two compounds were simultaneously administered orally to CD-1 mice, intraperitoneally to Sprague-Dawley rats, or subcutaneously to NMRI mice.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 99 (1989)]**PEER REVIEWED**

Animal studies in mice exposed to **toluene** at concentrations of 2.5-500 ppm demonstrated decreased host defense to respiratory infections.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1092]**PEER REVIEWED**

The cardiovascular response of 25 mongrel dogs following exposure to 30,000 ppm **toluene** for 9-10 min was complex. For most of the animals, there was no change in electrocardiogram readings for the first 3-4 min of exposure. The heartbeat then became rapid for several minutes, and was followed by a period of bradycardia. Immediately before death ventricular fibrillation was noted. ... Four of the dogs were particularly sensitive, their ventricular arrhythmias were transient and accompanied by fluctuations of blood pressure. The authors suggested that **toluene** had a direct effect on the septal and ventricular

muscles of the heart which permitted the development of fatal arrhythmias in sensitive dogs.
[Ikeda N et al; Forensic Sci Intern 44: 151-8 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.31 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Mice exposed for 3 hr to **toluene** at concentrations of 2.5-500 ppm exhibited increased, but not dose-related, susceptibility to respiratory infections when challenged by Streptococcus zooepidemicus. Pulmonary bactericidal activity was decreased at concentrations of 2.5 ppm and 100-500 ppm but not at concentrations of 5-50 ppm. There was no effect on susceptibility to infection with a **toluene** exposure of 1 ppm for 3 hr, 5 days (3 hr/day) or 4 wk (3 hr/day). The bactericidal activity of the lung was decreased during the 5-day treatment but not with the 4-wk treatment. The authors hypothesized that **toluene** exerted an adverse effect on alveolar macrophage function, thereby decreasing disease resistance.
[Aranyi C et al; Toxicol Lett 25: 103-10 (1985) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.39 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Studies have demonstrated that **toluene** can produce subtle changes in the auditory system. Intermediate exposure to **toluene** produced a permanent loss of hearing in the high frequency range (approximately 16 kHz) in rats exposed to 1200 ppm for 5-9 wk or 1000 ppm for 2 wk.
[Pryor GT, Rebert CS; Neurotoxicology 13: 225-34 (1992) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.44 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

In 3-day-old rats, daily 15 min exposures to **toluene** resulted in a dose-related increase in righting-reflex latency time. At each dose the righting-reflex latency decreased over the first 4 wk of exposure indicating that the animals had developed at least partial tolerance to the **toluene**. During the second 4-wk period, latencies increased again at the higher doses but were never as great as they were for the initial **toluene** exposure. The results for the second 4-wk period showed that there were limitations to the adaptive response at the higher **toluene** doses and that there were cumulative effects of exposure at these doses. Tolerance was probably the result of induction of **toluene** metabolizing enzymes.
[Lorenzana-Jimenez M, Salas M; Neurotoxicol Teratol 12: 353-7 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Concentrations of 480 ppm and above decreased the ability of trained rats to perform a sequence of lever press actions associated with a reward (milk). During training, the rats were divided into two groups. The reward presentation for one group was not accompanied by any noticeable external events. For the second group, the reward presentation was accompanied by light and sound stimuli. The effects of **toluene** on performance were less severe with the rats trained using the light and sound reinforcement. This suggests that behavior associated with external signals is less subject to disruption by **toluene** than behavior that is not accompanied by external reinforcement.
[Wood RW et al; Toxicol Appl Pharmacol 68: 462-72 (1983) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances &

Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Age ... influences neurological response after exposure to **toluene**. Young rats (50 days old) were affected by **toluene** to a lesser extent than older rats (120 days old) based on several measurements of escape latency 30 days after exposure to 30,000-40,000 ppm for 15 min/day.
[Castilla-Serna L et al; Arch Invest Med 22: 295-301 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Toluene exposure ... changes sleep patterns in animals. Both single episodes of **toluene** exposure (about 1000 ppm) and subchronic 8 hr/day exposures for 3 wk (about 600 ppm), changed patterns of sleep and wakefulness in rats. After the single exposures, there was a decrease in wakefulness and an increase in slow-wave sleep; a prolonged sleep latency was apparent for the 2 days following exposure. Latency was defined as the time interval between the end of the exposure period and the beginning of a particular phase of the sleep cycle. Following the 3 wk exposures, there was an increase in wakefulness during the dark period on the 2 days after exposure and a decrease in slow wave sleep on the first day.
[Arito H et al; Arch Toxicol 62: 76-80 (1988) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Brain levels of norepinephrine, dopamine, serotonin, vanillylmandelic acid, homovanillic acid, and 5-hydroxyindolacetic acid were altered in six areas of the brain in male CD-1 mice administered **toluene** (5-105 mg/kg/day) in their drinking water for a 28-day period. Significant increases of norepinephrine, dopamine, and serotonin were present in the hypothalamus at all dose levels. The maximum increase occurred with the 22 mg/kg/day dose and there were lesser increases for both the 5 and 105 mg/kg/day doses, giving biphasic response. Roughly similar fluctuations were seen in the concentrations of vanillylmandelic acid and homovanillic acid, which are metabolites of dopamine and norepinephrine and 5-hydroxyindolacetic acid, a serotonin metabolite. In corpus striatum, the levels of dopamine and serotonin were significantly increased at the two highest doses. The level of vanillylmandelic acid was also increased significantly at the same doses. In the medulla oblongata, the concentrations of norepinephrine, vanillylmandelic acid, and 5-hydroxyindolacetic acid were significantly increased at the 22 mg/kg/day dose, but not at the other doses, while the levels of serotonin were significantly increased at the 22 and 105 mg/kg/day doses. Norepinephrine concentrations were elevated in the midbrain. ...
[U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.61 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

To identify the frequency range most sensitive to **toluene**-induced auditory damage, the auditory function of adult Long-Evans rats exposed to 1750 ppm of **toluene** (6 h/day, 5 days/week, 4 weeks), was tested by recording auditory-evoked potentials directly from the round window of the cochlea. The present electrocochleographic findings do not support a specific mid- to high-frequency loss of auditory sensitivity. On the contrary, the electrophysiologic data, obtained for audiometric frequencies ranging from 2 to 32 kHz, showed a hearing deficit not only in the mid-frequency region (12-16 kHz), but also in the mid-low-frequency region (3-4 kHz). Actually, the effect of **toluene** was independent of the

frequency in our experimental conditions. Histological analysis was consistent with electrophysiologic data because a broad loss of outer hair cells occurred in both mid- and mid-apical coil of the organ of Corti.
[Lataye R et al; Neurotoxicol Teratol 21 (3): 267-76 (1999)]**PEER REVIEWED**

National Toxicology Program Studies:

Long-term studies were conducted by exposing groups of 60 rats /F344/N/ of each sex to 0, 600, or 1,200 ppm **toluene** by inhalation, 6.5 hours per day, 5 days per week. Groups of 60 /B6C3F1/ mice of each sex were exposed at 0, 120, 600, or 1,200 ppm on the same schedule. ... Animals were exposed to **toluene** for 103 weeks. Nephropathy was seen in almost all rats, and the severity was somewhat increased in exposed rats. A rare renal tubular cell carcinoma in a female rat and an equally uncommon sarcoma of the kidney in another female rat were seen in the 1,200 ppm exposure group. Erosion of the olfactory epithelium and degeneration of the respiratory epithelium were increased in exposed rats. Inflammation of the nasal mucosa and metaplasia of the olfactory epithelium were increased in exposed female rats. A rare squamous cell carcinoma of the nasal mucosa was seen in one female rat at 1,200 ppm. A squamous cell papilloma of the forestomach was observed in one female rat at 1,200 ppm, and a squamous cell carcinoma was observed in a second female rat at 1,200 ppm. No chemically related neoplasms were found in male rats, and the one nasal, two kidney, and two forestomach neoplasms observed in female rats were considered not to be associated with inhalation exposure to **toluene**. For mice, no biological important increases were observed for any nonneoplastic or neoplastic lesions.

TSCA Test Submissions:

Neurotoxicity was determined in groups of rats (4 male and 4 female, strain not reported) exposed by inhalation to 0,100, or 1500 ppm **toluene** (purity not reported) 6 hrs/day, 5 days/week for periods up to 27 weeks. Histological sections of selected areas of the brainstem were made for the upper medulla oblongata (including dorsal and ventral cochlear and vestibular nuclei), lower metencephalon (including superior olivary nuclei, trapezoid body and ventral cochlear nuclei), upper metencephalon (including the lateral lemniscus, superior olivary nuclei, cochlear and vestibular nuclei, and inferior colliculus) and the mesencephalon-diencephalon junction (including the medial geniculate). The investigators reported that the "vast majority" of sections from animals exposed to **toluene** were indistinguishable from controls. Shrunken and darkly stained neurons were observed in the corpus trapezoid of one animal exposed to 100 ppm and another exposed to 1500 ppm **toluene**; these were present in only one section and not in sufficient quantity to be considered a positive response by the investigators. Statistical analysis of the results was not reported.
[American Petroleum Inst.; Effects of Toluene Exposure on Auditory Pathways, Final Report. (1979), EPA Document No. 40-8450019, Fiche No. OTS0507495] **UNREVIEWED**

Chronic toxicity was evaluated in male and female Sprague Dawley rats (15/sex/group) exposed to **toluene** via inhalation at 0, 100 and 1500 ppm for 6 hrs/day, 5 days/week for 26 weeks. There were significant increases in the hematocrit and hemoglobin levels in females at 1500 ppm in the 13th week. There were significant differences in females at week 26 in the following: decreased mean blood clotting time and increased mean serum glutamic pyruvic transaminase at 100 ppm level, and decreases in glucose levels at 1500 ppm. There were no significant differences between treated and control animals in urinalysis.
[American Petroleum Institute; 26 Week Inhalation Toxicity Study in the Rat (1980), EPA Document No. FYI-AX-1081-0136, Fiche No. 0136-0] **UNREVIEWED**

Teratogenicity was evaluated in mated female CRL:COBS CD (SD) BR rats (27/group) exposed to **toluene** by inhalation at nominal concentrations of 0, 100 or 400 ppm on gestation days (GD) 6-15 for 6 hrs/day. The adult female rats were sacrificed on GD 20 and examined. There were no significant differences observed between treated and control animals in the following: maternal mortality, body weights, food consumption, examination of tissues and organs at necropsy (except an insignificant number of observations of mottled lungs in 4 high-dose group rats), pregnancy rate, live litters, implantation sites, resorptions, litters with resorptions, dead pups, litters with dead pups, live

pups/implantation site, mean live litter size, average pup weights, fetal sex ratio, examination of soft tissues of the head, thoracic and visceral organs, and skeletal abnormalities.

The ability of **toluene** to induce specific locus mutations at the TK locus in cultured L5178Y mouse lymphoma cells (Mouse Lymphoma Mutagenesis Assay) was evaluated in the presence and absence of mouse liver S9 metabolic activation. Based on preliminary toxicity tests, both nonactivated and S9-activated cultures were treated with 0.30, 0.20, 0.15, 0.10, or 0.050 ul/ml produced a range of 7 - 78% total growth for nonactivated cultures and from 60 - 138% total growth for S9-activated cultures. None of the nonactivated or activated cultures produced mutant frequencies significantly greater than the solvent (DMSO) controls.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain D4, both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, **toluene**, diluted with acetone, was tested for mutagenicity at concentrations up to 5.0 ul/plate using both the plate and suspension assay methods. **Toluene** did not cause a positive response in any of the bacterial or yeast tester strains, either with or without metabolic activation.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in a dominant lethal assay using three groups of male CD-1 mice (12/group) receiving whole body exposures to nominal concentrations of test material at 0, 100 or 400 ppm for 6 hrs/day, 5 days/week for 8 weeks. Following exposure, each male was mated with two untreated females/week for two consecutive weeks. Females were sacrificed 14 days after the midweek of mating. There was no effect of treatment for all dosed male mice as indicated by mortality, body weight and in-life physical observations. There were no significant differences between treated and control females with respect to fertility indices, average number of implants/pregnant female, average number of dead implants/pregnant female, and proportions of female with one or more dead implants.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene, Mouse Dominant Lethal Assay, Final Report. (1981), EPA Document No. FYI-AX-1081-0136, Fiche No. OTS0000136-0] **UNREVIEWED**

The ability of **toluene** to cause chromosome aberrations in the bone marrow cells of male Charles River rats exposed by intraperitoneal injection at dose levels of 0, 0.025, 0.082 or 0.247 cc/kg (in DMSO solvent, 0.65 cc/rat/day), either once in an acute study (15 rats/group) or once each day for 5 days in a subchronic study (5 rats/group) was evaluated. Five rats/group in the acute study were sacrificed 6, 24 or 48 hrs following dosing and the rats in the subchronic study were sacrificed 6 hrs after administration of the last dose. 50 cells/animal were scored for chromosome aberrations. None of the cells from any of the treated animals exhibited a significant increase in the frequency of chromosome aberrations.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The percutaneous absorption of **toluene** was evaluated in six human volunteers. A glass ring having an area of 13cm(2) was placed against the palm and 2ml of 14C-**toluene** was applied. After one minute the ring was removed and adherent liquid allowed to evaporate. All urine was collected and analyzed for radioactive content until background levels of activity were approached. **Toluene** absorption was very low, averaging .022ul/cm(2) for the six human subjects.
[Thomas J. Franz M.D.; Absorption of Petroleum Products Across the Skin of Man and Monkey, Draft Report, (no date), EPA Document No. FYI-AX-0187-0185, Fiche No. OTS0000185-4] **UNREVIEWED**

Metabolism/Pharmacokinetics:

Metabolism/Metabolites:

Toluene is extensively metabolized via oxidation to benzyl alcohol then to benzaldehyde by alcohol dehydrogenase. Further oxidation then forms benzoic acid. Conjugation with glycine produces the major metabolite, hippuric acid, which is excreted in the urine. Benzyl glucuronide is formed in smaller amounts by conjugation with glucuronic acid.

[ANGERER J; INT ARCH OCCUP ENVIRON HEALTH 43 (1): 63 (1979)]**PEER REVIEWED**

In rats, approx 0.5%-1.1% of the dose is converted to o-cresol and p-cresol and is excreted as glucuronide and sulfate conjugates.
[Bakke OM, Scheline RR; Tox Appl Pharm 16: 691-700 (1970) as cited in NRC; Alkyl Benzenes p.221 (1981)]**PEER REVIEWED**

In mammalian species, acidic metabolites are conjugated with glycine to form hippuric acid and phenylacetic acid. In humans, the phenylacetic acid metabolite is also conjugated with glutamine to form phenacetylglutamine.
[James MO et al; Proc R Soc Lond Ser B 182: 25-35 (1972) as cited in NRC; Alkyl Benzenes p.219 (1981)]**PEER REVIEWED**

The association between occupational **toluene** exposure and blood and adipose tissue **toluene** concentrations was examined. Breathing zone samples were monitored for **toluene** in two Swedish rotogravure printing facilities. Sc adipose tissues were taken from 37 workers after work on Thursday or Friday and analyzed for **toluene**. Venous blood samples were taken from 11 workers after work on Friday and at various times over the following weekend and assayed for **toluene**. Blood and adipose tissue samples were obtained from 11 other workers immediately after work and after 63 and 135 hours nonexposure and analyzed for **toluene**. Blood samples were also taken from 21 unexposed workers and analyzed for **toluene**. Attempts were made to fit the blood **toluene** data to various pharmacokinetics models. Airborne **toluene** concentrations in the printing factories ranged from 8 to 416 mg/cu m, median 75 mg/cu m. Blood **toluene** concentrations in the unexposed workers were below the detection limit,

0.01 umole/l. Blood samples obtained immediately after work contained 0.22 to 21.4 umole/l **toluene**. Elimination of **toluene** from the blood could be described by a three compartment model having median halftimes of 9 minutes, 2 hours, and 79 hours. **Toluene** was eliminated from adipose tissue with a median halftime of 79 hours. Adipose tissue concentrations were significantly associated with the workers' exposure to airborne **toluene** during the previous week. Adipose tissue **toluene** concentrations were significantly correlated with blood **toluene** concentrations after 70 hours exposure. It was concluded that the prolonged presence of **toluene** in the blood means that there is an endogenous exposure from adipose tissue depots that continues long after occupational exposure has ended.
[Nise G et al; Br J Ind Med 46 (6): 407-11 (1989)]**PEER REVIEWED**

Evidence has suggested that there is an ethnic related difference in organic solvent metabolism in humans; analyses were thus made to obtain evidence of strain differences in animals to assist in consolidating the observation in workers. Female Donryu, Fischer, Sprague-Dawley, and Wistar rats were exposed to **toluene** at dose levels of 5, 45, 500, 2500, and 3500 ppm for 8 hours in a dynamic flow type exposure system. Urine samples were collected for 24 hours from the start of exposure. While the variation in free p-cresol excretion was wide among the rats of the same strain exposed to **toluene** at the same concentration, it was also noted that the four strains tested could be classified into two groups depending on the free p-cresol levels at **toluene** concentrations up to 500 ppm. No significant differences were noted between Sprague-Dawley and Wistar strains nor between Donryu and Fischer strains at the 45 and 500 ppm levels. However, there were significant differences between these two groups. At higher concentrations of 2500 and 3500 ppm, the increase in the free p-cresol levels was remarkable only in Donryu rats, reaching the levels of Sprague-Dawley and Wistar rats, while the level in Fischer rats remained unchanged.
[Inoue O et al; Bull Environ Contam Toxicol 43 (1): 74-9 (1989)]**PEER REVIEWED**

The mutual metabolic suppression between benzene and **toluene** was studied. The subjects, 190 male Chinese workers employed in shoe manufacturing, printing, audio equipment manufacture, and automobile industries, were divided into four groups based on occupational exposure: 65 were exposed to benzene, 35 to **toluene**, 55 to both compounds, and 35 served as comparisons. The arithmetic mean exposure level of benzene was 31.9 and of **toluene** 44.7 ppm. The mixture contained benzene at 17.9 +/29.3 and **toluene** at 20.5 +/25.8 ppm. The exposure levels were measured using individuals diffusive samplers. The geometric mean levels of the metabolites, phenol, catechol, hydroquinone, hippuric acid, and o-cresol, in unexposed workers were 6.9, 9.4, 4.8, 72.5, and 0.066 mg per liter, respectively. Values corrected for creatinine and specific gravity were different from the values cited above. Multiple correlation coefficients for benzene exposure versus its three metabolites were for phenol, 0.740; for catechol, 0.629; and for hydroquinone, 0.726. Multiple correlation coefficients for **toluene** and its two metabolites were 0.649 for hippuric acid and 0.583 for o-cresol. The slopes of regression lines for the exposure to benzene in the presence of **toluene** were less than half of those obtained when the workers were exposed to benzene alone; however, the regression lines for benzene in mixture versus catechol were about 80% or higher than the lines observed with benzene as the sole pollutant. The regression lines for **toluene** in the mixture and excretion level of hippuric acid and o-cresol showed reduced metabolic conversion compared to when exposure was limited to **toluene** alone. It was concluded that simultaneous exposure to benzene and **toluene** results in mutual suppression of metabolism yielding the urinary metabolites phenol, hydroquinone, hippuric acid, and o-cresol.

The urinary excretion of hippuric acid and o-cresol in humans was measured after a 7 hr exposure to **toluene** at a constant concn of 100 ppm but with a time-weighted avg of 100 ppm. In study A, 4 men were exposed to clean air and to constant and varying concns of **toluene** in combination with rest and with 100 W exercise for 140 min exercise increased the end-exposure excretion rate of hippuric acid and o-cresol by 47 and 114%, respectively. After exposure, all excess hippuric acid was excreted within 4 hr, while o-cresol was eliminated with a half-life of approx 3 hr. Alveolar air concn of **toluene** was 21-31 ppm during constant exposure and 13-57 ppm during varying exposure, but no difference in mean alveolar **toluene** concn or in metabolite excretion was seen between the exposure schedules. In study B, 32 men and 39 women aged between 31 and 50 yr were exposed once to either clean air or ... or varying concns of **toluene**. The background excretion rate of hippuric acid was 0.97 mg/min (1.25 g/g creatinine) and rose to 3.74 mg/min (3.90 g/g creatinine) during the last 3 hr of exposure to 100 pmm **toluene**. The corresponding figures for o-cresol were 0.05 ug/min (0.08 mg/g creatinine), and 2.04 ug/min (2.05 mg/g creatinine). The individual creatinine excretion rate was considerably influenced by sex, body wt, and smoking habits, thus influencing the metabolite concn standardized in relation to creatinine. Thus, both metabolites are estimates of **toluene** exposure; o-cresol is more specific than hippuric acid, but the individual variation in excretion of both metabolites is large, and when implementing either of them as biological exposure indexes, the influence of sex, body size, age as well as consumption of tobacco and alcohol has to be considered.
[Baelum J et al; Int Arch Occup Environ Health 59 (3): 281-94 (1987)]**PEER REVIEWED**

The distribution of radioactivity in pregnant mice was registered at different time intervals (0-24 hr) after a 10 min period of inhalation of **toluene**. ... Autoradiographic and liq scintillation methods were used to make possible the distinction between volatile, water sol, and firmly tissue bound radioactivity. **Toluene** reached high concns immediately after inhalation in lipid rich tissues (brain and fat) and well perfused organs (liver and kidney) but were rapidly eliminated resulting in low concns at 1 hr in all maternal tissues, except fat. Metabolites reached peak levels around 30 min to 1 hr after inhalation, but were also relatively rapidly eliminated. ... One exception was the very strong accumulation of water sol metabolites at 4 and 24 hr in the nasal mucosa and olfactory bulb after inhalation of **toluene**. Volatile radioactivity was observed in the placenta and fetuses immediately and up to 1 hr after inhalation of solvent at all stages of gestation. The fetal levels were, however, much lower than in maternal tissues. In early gestation, an even distribution pattern was observed, while the fetal liver reached a higher concn than other fetal tissues in late gestation. In similarity with maternal tissues, fetal tissues reached the highest levels of metabolites 30 min to 1 hr after inhalation. A retention in uterine fluid was seen at 4 hr. Otherwise no retention of metabolites was observed in the fetoplacental unit. No firmly tissue bound metabolites of the studied solvents were observed in the fetal tissues in late gestation, indicating no fetal capacity for formation of reactive metabolites.
[Ghantous H, Danielson BRG; Biol Res Pregnancy Perinatol 7 (3): 98-105 (1986)]**PEER REVIEWED**

A study was instituted to determine whether gavage dosing and inhalation exposure resulted in similar blood levels of **toluene**. Groups of male Sprague-Dawley rats were dosed with **toluene** either by gavage with 0.10, 0.25, 0.50, or 1.0 mg/kg/body weight or through exposure to atmospheres containing 200 to

1000 ppm **toluene**. Blood samples were taken at 0.5, 1.0, 2.0, 4.0, 6.0, and 24.0 hours following dosing. Steady state blood concentrations were reached for both inhaled doses within 30 minutes of the exposure. After 6 hours the steady state **toluene** blood concentrations for the 200 and 1000 ppm dose levels were 2.89 and 37.23 ppm, respectively. For the oral doses, the peak blood **toluene** concentration increased with increasing dosage. Blood profiles from higher oral doses more closely approximated the steady state inhalation blood profiles. At 24 hours following dosing, blood **toluene** levels from all doses by either route were below detectable levels, suggesting minimal carry over of **toluene** concentrations from one day to the next. An equation was derived which will allow the gavage dose of **toluene** to be made equivalent to an inhalation dose. Based on results of other studies, it was suggested that blood **toluene** levels following sc injection more closely resemble those obtained following inhalation than do blood levels after gavage. However, it is possible to obtain blood concentrations of **toluene** similar to those generated by a 6 hour inhalation exposure to 1000 ppm through gavage dosing.
[Sullivan MJ, Conolly RB; Environ Research 45 (1): 64-70 (1988)]**PEER REVIEWED**

An investigation was carried out to quantitate the effect of pulmonary ventilation on uptake and biological concentrations of six organic solvents. Tested solvents were acetone, styrene, **toluene**, xylenes, methylchloroform, and tetrachloroethylene. Lung uptake and urinary concentration (Cu) were measured in 15 volunteers, 24 to 52 years old, exposed in a chamber for 2 or 4 hours at rest, 2 hours with three alternations of light exercise, 1 hour of light exercise, or 30 minutes or more strenuous exercise. Environmental levels and urinary concentration were measured in 528 occupationally exposed workers before and after 4 hours of work at a light task (pulmonary ventilation 12 to 18 liters per minute). For volunteers, uptake and urinary concentration values were significantly correlated. Environmental levels and urinary concentration showed a close relationship for occupational exposure. Biological equivalent exposure limits corresponding to threshold limit value (TLV) time weighted averages were derived from urinary concentration values. For acetone, styrene, and xylenes, uptake for a given time and exposure level was dependent only on ventilation. The **toluene** retention index was slightly lower for exercise than for rest, and uptake was ventilation dependent during rest and ventilation and retention index dependent during exercise. Retention indices decreased with increasing ventilation at rest and during exercise for tetrachloroethylene and methylchloroform. Their urinary concentration values were ventilation and retention index dependent. Methylchloroform uptake was higher during light versus heavy exercise. It was concluded that work load profoundly affects the absorbed amount of chemical and should be a factor in implementation of biological exposure indices and TLVs.

Exposure to **toluene** causes both reversible and irreversible changes in the central nervous system. The effects of **toluene** inhalation on some specific enzymes and glutamate and GABA receptor binding in defined parts of the rat brain were studied following several exposure schemes. The activities of the transmitter synthesizing enzymes glutamic acid decarboxylase (GAD), choline acetyltransferase (ChAT) and aromatic amino-acid decarboxylase (AAD) were used as markers for permanent loss of neuronal activity. Catecholaminergic neurons showed a 50% reduction in the brain stem after 4 weeks exposure to 250 and 1000 ppm **toluene**. Following 500 ppm of **toluene**, 16 hr/day for 3 months, a general increase in the activities was seen. This is most probably due to a reduction in total protein content, to which the activities were related. The neurotransmitters glutamate and GABA had their specific receptor binding increased in most of the brain areas studied, but decreased in some areas. The glial enzyme, glutamine synthetase, has its activity increased in the cerebellar hemisphere following 4 weeks exposure to 1000 ppm. This suggests that glial cells in the area may have proliferated, a frequent phenomenon following CNS damage.
[Bjornaes S, Naalsund Lu; Toxicol 49 (2-3): 367-74 (1988)]**PEER REVIEWED**

The effect of styrene, **toluene**, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of

the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or **toluene** in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.

The metabolic interaction of **toluene** and ethanol was studied in male rabbits having received ethanol (26.0 mmol/kg po), **toluene** (5.4 mmol/kg po) or both. Compared with ethanol alone, **toluene** given 2 hr after ethanol caused a significantly higher and more prolonged concentration of blood alcohol. A similar trend of blood alcohol was observed at the later stage with **toluene** given prior to ethanol. On the other hand, with simultaneous doses of the two substances, the blood **toluene** concentration was higher for the first 15-30 min than the ethanol control and the urinary excretion of hippuric acid, a main metabolite of **toluene**, was markedly decreased for the first 2 hr. The blood ethanol in this group, on the contrary, was reduced until 1 hr after administration. These results indicate that **toluene** and ethanol act reciprocally as competitive inhibitors in their metabolism after single administrations.
[Takahashi S et al; Arch Toxicol 59 (5): 307-10 (1987)]**PEER REVIEWED**

In an experimental human study, the effect of **toluene** and ethanol (alone or in combination) on psychophysiologic functions was studied in 12 men (22-44 yr of age). Each subject served as his own control. Subjects were exposed to **toluene** by inhalation at a concentration of 300 mg **toluene**/cu m air for 4.5 hr. Ethanol was ingested at a dose equivalent to 15 mmol ethanol/kg body weight. **Toluene** had no significant effect on the 4 performance tests. A significant but weak depression of heart rate was observed during sleep latency tests (1-2.5 beats/min, 0.001 <p< 0.01). There was a significant increase in reporting of headache (p< 0.05) and in reporting for all symptoms (nausea, headache, irritation) combined (p< 0.05). No interaction between ethanol and **toluene** was observed.

The aim of this study was to examine if the drug chlorzoxazone has any influence on the toxicokinetics of acetone and **toluene**. Chlorzoxazone is mainly metabolized by the same enzyme (Cytochrome P450 2E1) as ethanol and many other organic solvents. Ten male volunteers were exposed to solvent vapor (2 hr, 50 watt) in an exposure chamber. Each subject was exposed to acetone only (250 ppm), acetone + chlorzoxazone, **toluene** (50 ppm) only, **toluene** + chlorzoxazone, and chlorzoxazone only. Chlorzoxazone (500 mg) was taken as two tablets 1 h prior to solvent exposure. Samples of blood, urine and exhaled air were collected before, during and until 20 h post exposure. The time-concentration curves of acetone and **toluene** in blood were fitted to one- and four-compartment toxicokinetic models, respectively. Except for a delayed excretion of hippuric acid in urine, no effects on the **toluene** toxicokinetics were seen after chlorzoxazone treatment. Small increases in chlorzoxazone plasma levels were seen after exposure compared to chlorzoxazone alone. These interactions, although statistically significant, seem to be small compared to the interindividual variability on metabolism and toxicokinetics.

[Ungvary G et al; Teratology 27 (2): 261-9 (1983)]**PEER REVIEWED**

The metabolic interaction of **toluene** and ethanol was studied in male rabbits having received ethanol (26.0 mmol/kg po), **toluene** (5.4 mmol/kg po) or both. Compared with ethanol alone, **toluene** given 2 hr after ethanol caused a significantly higher and more prolonged concentration of blood alcohol. A similar trend of blood alcohol was observed at the later stage with **toluene** given prior to ethanol. On the other hand, with simultaneous doses of the two substances, the blood **toluene** concentration was higher for the first 15-30 min than the ethanol control and the urinary excretion of hippuric acid, a main metabolite of **toluene**, was markedly decreased for the first 2 hr. The blood ethanol in this group, on the contrary, was reduced until 1 hr after administration. These results indicate that **toluene** and ethanol act reciprocally as competitive inhibitors in their metabolism after single administrations.
[Takahashi S et al; Arch Toxicol 59 (5): 307-10 (1987)]**PEER REVIEWED**

In an experimental human study, the effect of **toluene** and ethanol (alone or in combination) on psychophysiologic functions was studied in 12 men (22-44 yr of age). Each subject served as his own control. Subjects were exposed to **toluene** by inhalation at a concentration of 300 mg **toluene**/cu m air for 4.5 hr. Ethanol was ingested at a dose equivalent to 15 mmol ethanol/kg body weight. **Toluene** had no significant effect on the 4 performance tests. A significant but weak depression of heart rate was observed during sleep latency tests (1-2.5 beats/min, 0.001 <p< 0.01). There was a significant increase in reporting of headache (p< 0.05) and in reporting for all symptoms (nausea, headache, irritation) combined (p< 0.05). No interaction between ethanol and **toluene** was observed.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Toluene is released into the atmosphere principally from the volatilization of petroleum fuels and **toluene**-based solvents and thinners and from motor vehicle exhaust. **Toluene**'s production and use as an intermediate in the production of benzoic acid, benzaldehyde, benzene, explosives, dyes and many other organic compounds may also result in its release to the environment through various waste streams. **Toluene** has been detected in emissions from volcanos, forest fires and crude oil. If released to air, a vapor pressure of 28.4 mm Hg at 25 deg C indicates **toluene** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **toluene** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 3 days. **Toluene** may also be degraded in the atmosphere by reaction with nitrate radicals and ozone molecules, but these reactions are too slow to be environmentally important. If released to soil, **toluene** is expected to have high to moderate mobility based upon Koc values in the range of 37-178. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 6.64X10-3 atm-cu m/mole. **Toluene** may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation is expected to occur rapidly in soil surfaces, with half-lives in the range of several hours to 71 days. If released into water, **toluene** is not expected to adsorb to suspended solids and sediment based upon a Koc of 166 measured in lake sediment. Biodegradation is expected to occur rapidly in water, with reported half-lives of 4 and 56 days in aerobic and anaerobic water, respectively. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1 hour and 4 days, respectively. Measured BCF values of 13 and 90 in fish suggest bioconcentration in aquatic organisms is low to moderate. Hydrolysis is not expected to be an important environmental fate process for **toluene** due to lack of hydrolyzable functional groups. Exposure to **toluene** may occur

occupationally during its production or subsequent use, particularly as a solvent or in gasoline, via dermal and respiratory routes. The main route of exposure for the general population will be through inhalation from contaminated air and handling of gasoline as well as ingestion of contaminated drinking water and food, and exposure to some consumer products. (SRC)
PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,625,598 workers (288,299 of these are female) are potentially exposed to **toluene** in the US(1). Occupational exposure to **toluene** may occur through inhalation and dermal contact with this compound at workplaces where **toluene** is produced or used(SRC). The general population may be exposed to **toluene** via inhalation of ambient air, ingestion of food and drinking water, handling of gasoline, and exposure to some consumer products where **toluene** is used as a solvent(SRC).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983)]**PEER REVIEWED**

Toluene was detected in hairdresser salons in Norway at concns of 0.04-0.11 mg/cu m(1). The time weighted average (TWA) of **toluene** in the workplace air of a municipal waste composting facility was reported as 188,000 ug/cu m(2). In a 1989 Danish survey on chemical exposures(3), the number of worker exposure events for **toluene** were documented: manufacturing of metals, 420; manufacturing of metal fabricated products 64,000; electrical machinery and apparatus, 1,500; manufacture of transport equipment 2,700; painters and carpenters 15,000; construction workers, 5,400; publishing and printing, 6,300; wholesale trades, 5,000; textile and leather manufacturing, 4,400; wood and furniture manufacturing, 5,900; manufacture of chemicals, 8,700; manufacture of paints and petroleum, 1,400; manufacture of non-metallic mineral products, 2,300; manufacture of optical instruments, 2,500 manufacture of plastic and boat building, 1,100; sewage and refuse disposal, 99; agriculture and forestry, 11,000; health services, 2,600. The total number of work related exposure events was 140,000(3). **Toluene** was detected in the workplace air of glass fiber manufacturing plants and high temperature sealing component and clutch lining plants at a mean concn of 65 ppm(4).

Environmental Biodegradation:

Toluene is readily degradable in a variety of standard biodegradability tests using sewage seed or sludge inoculums(1-7). Degradation has been observed in several die-away tests using seawater or estuarine water(9-12). The degradation rate is much faster in systems which have been contaminated by oil(9,10). Complete degradation has been observed in 4 days and 22 days in a marine mesocosm with summer and spring conditions, respectively(12), and 10 days in a 1% gas oil mixture in a North Sea coast water inoculum(8). A 90 day half-life in uncontaminated estuarine water was reduced to 30 days in oil-polluted water(10). The half-life in water collected near Port Valdez, Alaska was 12 days(9). 1.5 mM and 3 mM Ring-labeled **toluene** added to a methanogenic inoculum originally enriched from sewage sludge and incubated at 35 deg C for 60 days resulted in 3.6 and 4.5% 14-C final activity respectively(13).

Complete biodegradation of **toluene** was observed in lab microcosm tests during a 40 hour incubation period using soils previously exposed to **toluene**(1). **Toluene** was rapidly degraded in soil column experiments using acclimated soil at a rate of 8-35 mg/kg-day, and the rate followed zero-order kinetics(2). First-order degradation rate constants of 0.0005 to 0.0063 day-1 were measured for **toluene** in a gasoline-contaminated aquifer zone(3). These rate constants correspond to half-lives of 100-1,386 days(3). A first-order biodegradation rate constant of 0.045 day-1 was reported for **toluene** in an anaerobic petroleum contaminated aquifer, corresponding to a biodegradation half-life of 15 days(4). **Toluene** was rapidly biodegraded by indigenous mixed cultures in sandy aquifer material and pure cultures isolated from the aquifer(5). The zero-order rate constant for the aquifer material was 23 mg/l-day and had a lag period of 2 days(5). The half-life of **toluene** in aerobic and anaerobic water was reported as 4 and 56 days, respectively(6). The biodegradation half-life in various soils was reported as several hours to 71 days(7).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **toluene** with photochemically-produced hydroxyl radicals has been measured as 5.96X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 3 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1). The rate constant for the vapor-phase reaction of **toluene** with nitrate radicals has been measured as 6.8X10-17 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 491 days at an atmospheric concentration of 2.4X10+8 nitrate radicals per cu cm(2). The rate constant for the vapor-phase reaction of **toluene** with ozone has been measured as 4.1X10-22 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 27,950 days at an atmospheric concentration of 7X10+11 ozone molecules per cu cm(3). **Toluene** is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(4) nor to directly photolyze due to the lack of absorption in the environmental UV spectrum.

Washington, DC: Amer Chem Soc pp. 7-4, 7-5 (1990)]**PEER REVIEWED**

Environmental Bioconcentration:

The BCF of **toluene** in eels was reported as 13(1) and the BCF in golden ide was reported as 90(2). According to a classification scheme(3), this BCF data suggests bioconcentration in aquatic organisms is low to moderate.
[(1) Ogata M, Miyake Y; Water Res 12: 1041-4 (1978) (2) Freitag D et al; Chemosphere 14: 1589-1616 (1985) (3) Franke C et al; Chemosphere 29: 1501-14 (1994)]**PEER REVIEWED**

Soil Adsorption/Mobility:

In association with clay minerals, **toluene**'s adsorption is inversely proportional to the pH of the soil. Approximately 40-70% of **toluene** applied to the surface of sandy soils is volatilized.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 90 (1989)]**PEER REVIEWED**

The Koc of **toluene** was reported as 178 in a sandy soil(1) and as 37 (Wendover silty loam), 160

(Grimsby silt loam), 160 (Vaudreil sandy loam) and 46 (sandy soil)(2). The Koc of **toluene** in lake sediment was measured as 166(3). According to a classification scheme(4), this Koc data suggests that **toluene** is expected to have high to moderate mobility in soil.
[(1) Wilson JT et al; J Environ Qual 10: 501-6 (1981) (2) Nathwani JS, Phillips CR; Chemosphere 6: 157-62 (1977) (3) Kan AT et al; Environ Sci Technol 32: 892-902 (1998) (4) Swann RL et al; Res Rev 85: 17-28 (1983)]**PEER REVIEWED**

Volatilization from Water/Soil:

The Henry's Law constant for **toluene** is 6.64X10-3 atm-cu m/mole(1). This Henry's Law constant indicates that **toluene** is expected to volatilize rapidly from water surfaces(2). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec)(2) is estimated as 1 hour(SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec)(2) is estimated as 4 days(SRC). **Toluene**'s Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). **Toluene** may volatilize from dry soil surfaces based upon a vapor pressure of 28.4 mm Hg at 25 deg C(3).

Environmental Standards & Regulations:

FIFRA Requirements:

Toluene is exempted from the requirement of a tolerance when used as a solvent or cosolvent in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only.
[40 CFR 180.1001(d) (7/1/99)]**PEER REVIEWED**

TSCA Requirements:

Pursuant to section 8(d) of TSCA, EPA promulgated a model Health and Safety Data Reporting Rule. The section 8(d) model rule requires manufacturers, importers, and processors of listed chemical substances and mixtures to submit to EPA copies and lists of unpublished health and safety studies. **Toluene** is included on this list.
[40 CFR 716.120 (7/1/99)]**PEER REVIEWED**

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 1000 lb or 454 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/99)]**PEER REVIEWED**

RCRA Requirements:

U220; As stipulated in 40 CFR 261.33, when **toluene**, as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).
[40 CFR 261.33 (7/1/99)]**PEER REVIEWED**

F005; When **toluene** is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F005), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/99)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Toluene** is produced, as an intermediate or a final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/99)]**PEER REVIEWED**

Listed as a hazardous air pollutant (HAP) generally known or suspected to cause serious health problems. The Clean Air Act, as amended in 1990, directs EPA to set standards requiring major sources to sharply reduce routine emissions of toxic pollutants. EPA is required to establish and phase in specific performance based standards for all air emission sources that emit one or more of the listed pollutants. **Toluene** is included on this list.
[Clean Air Act as amended in 1990, Sect. 112 (b) (1) Public Law 101-549 Nov. 15, 1990]**PEER REVIEWED**

Clean Water Act Requirements:

Toxic pollutant designated pursuant to section 307(a)(1) of the Federal Water Pollution Control Act and is subject to effluent limitations.
[40 CFR 401.15 (7/1/99)] **QC REVIEWED**

Toluene is designated as a hazardous substance under section 311(b)(2)(A) of the Federal Water Pollution Control Act and further regulated by the Clean Water Act Amendments of 1977 and 1978. These regulations apply to discharges of this substance. This designation includes any isomers and hydrates, as well as any solutions and mixtures containing this substance.
[40 CFR 116.4 (7/1/99)] **QC REVIEWED**

For the protection of human health from the toxic properties of **toluene** ... the ambient water criterion is determined to be 14.3 mg/l.
[USEPA; Quality Criteria for Water 1986: Toluene (1986) EPA

440/5-86-001] **QC REVIEWED**

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Numbers. ... Isolate spill or leak area immediately for at least 50 to 100 meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training

(DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, isolate for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or regular foam. Large fires: Water spray, fog or regular foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs

Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Preventive Measures:

Drench-type showers, eye-wash fountains should be installed and maintained to provide prompt, immediate access.
[NIOSH; Criteria Document: Toluene p.9 (1973) DHEW Pub. NIOSH 73-11023]**PEER REVIEWED**

Open lights or other agencies liable to ignite the vapor should be excluded from areas where the liquid is liable to be exposed in use or by accident.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 2185]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **toluene**/. ... Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents are highly flammable.
[Hart C; J Environ Health 49 (5): 282-86 (1987)]**PEER REVIEWED**

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 310]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to knock-down vapors.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

Personnel protection: Avoid breathing vapors. Keep upwind. ... Do not handle broken packages unless wearing appropriate personal protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

If material leaking (not on fire): Consider evacuation from downwind area based on amount of material spilled, location and weather conditions.

Threshold Limit Values:

8 Hr Time Weighted Avg (TWA) 50 ppm, skin
[American Conference of Governmental Industrial Hygienists. TLVs and BEIs. Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices. Cincinnati, OH. 2000. 67]**QC REVIEWED**

Biological Exposure Index (BEI): Hippuric acid in urine at end of shift is 1.65 g/g creatinine. The determinant is usually present in a significant amt in biological specimens collected from subjects who have not been occupationally exposed. Such background levels are incl in the BEI value. The determinant is nonspecific, since it is observed after exposure to some other chemicals. These nonspecific tests are preferred because they are easy to use and usually offer a better correlation with exposure than specific tests. In such instances, a BEI for a specific, less quantitative biological determinant is recommended as a confirmatory test.
[American Conference of Governmental Industrial Hygienists. TLVs and

BEIs. Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices. Cincinnati, OH. 2000. 101]**QC REVIEWED**

Biological Exposure Index (BEI) adoption (1998): **Toluene** in venous blood prior to last shift of workweek is 0.5 mg/l.

[SRI]**PEER REVIEWED**

Catalytic reforming of petroleum steams accounts for 87% of total **toluene** production. An additional 9% is separated from pyrolysis gasoline produced in steam crackers during manufacture of ethylene and propylene ... coal-tar separation from coke ovens produces 1% of total **toluene** ... up to 2% of the **toluene** produced is obtained as a by-product from styrene manufacture.

[DCE/NCI; Monograph On Human Exposure To Chemicals In The Workplace: Toluene p.2-1 (1985)]**PEER REVIEWED**

(1) By catalytic reforming of petroleum. (2) By fractional distillation of coal tar light oil.

Laboratory Methods:

Clinical Laboratory Methods:

NIOSH Method: 8002. Analyte: **Toluene**. Specimen: Venous blood, after 2 or more hours of exposure. Procedure: Gas chromatography, hydrogen-air flame ionization detector. The precision/RSD is 0.098 (1 ug/ml blood) and the recovery is 0.93 @ 2 ug/ml blood. The working range is 1 to 600 ug/ml. Applicability: **Toluene** is commonly found in trace amounts in humans working in the paint spray industry. Interferences: Ethanol in excess of the stated range increased blood **toluene** concentration. When substances other than the analytes are present in the blood, record their identities to determine possible interferences.
[U.S. Department of Health and Human Services, Public Health Service.

Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 8002-1]**PEER REVIEWED**

A procedure for the determination of **toluene** in blood by the purge and trap method is described ... has a linear range which extends up to at least 1500 ug/l ... detection limit ... is estimated to be less than 7.5 ug/l ...
[Cocheo V et al; Am Ind Hyg Assoc 43 (12): 938-41 (1982)]**PEER REVIEWED**

An automated high performance liquid chromatographic method for the direct determination of urinary concentrations of p-methylhippuric acids, and metabolites of **toluene** is described. A mixed solution of 5 mM potassium phosphate monobasic/acetonitrile (90/10) was used as a mobile phase . The method is simple and specific. Urine can be analyzed without solvent extraction.
[Ogata M, Taguchi T; Int Arch Occup Environ Health 59 (3): 263-72 (1987)]**PEER REVIEWED**

NIOSH Method 4000. Analyte: **Toluene**. Procedure: Gas chromatography, hydrogen-air flame ionization detector. For **toluene** this method has an estimated detection limit of 0.01 mg/sample. The overall precision/RSD is 0.022. Applicability: The working range is 13 to 660 ppm (50 to 2500 mg/cu m) for a 4 hr sample. Interferences: None identified.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 4000-1]**PEER REVIEWED**

NIOSH Method 1501. Analyte: **Toluene**. Matrix: Air. Procedure: Gas chromatography, hydrogen-air flame ionization detector. For **toluene** this method has an estimated detection limit of 0.001 to 0.01 mg/sample with capillary column/sample. The overall precision/RSD is 0.011. Applicability: This method is for peak, ceiling and TWA determinations of aromatic hydrocarbons. Interferences: Use of the recommended column will prevent interferences by alkanes (less or equal to C10).
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 1501-1]**PEER REVIEWED**

EPA Method 524.1. Purge-and-Trap Gas Chromatography/Mass Spectrometry. The method is applicable for the determination of volatile organic compounds in water, finished drinking water, raw source water, or drinking water in any treatment stage. For **toluene** the method has a detection limit of 0.08 ug/l and a standard deviation of 4.1%.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 524.2. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the determination of volatile aromatic compounds in water including finished drinking water, raw source water, and drinking water in any treatment stage. For **toluene** the method has a detection limit of 0.11 ug/l and a relative standard deviation of 8.0% with a wide bore capillary column, and a method detection limit of 0.08 ug/l and a relative standard deviation of 5.9% with a narrow bore capillary column.
[USEPA; Methods for the Determinatioon of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 602. Purge-and-Trap Gas Chromatography with photoionization detection for the determination of purgeable aromatics including **toluene** in municipal and industrial discharges. Under the prescribed conditions for **toluene** the detection limit is 0.2 ug/l. The method is applicable for use in the concentration range from the method detection limit to 100 times that limit. Precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of the sample matrix.
[40 CFR 136 97/1/91)]**PEER REVIEWED**

EPA Method 624. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the analysis of purgeable organics including **toluene** in the municipal and industrial discharges. Under the prescribed conditions, for **toluene** the method has a detection limit of 6.0 ug/l. Precision and method accuracy were

found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 1624. Isotope Dilution Purge-and-Trap Gas Chromatography/Mass Spectrometry. This method is applicable for the determination of volatile organic compounds in municipal and industrial discharges. By adding a known amount of a labeled compound to every sample prior to purging, a correction of recovery of the pollutant can be made. If labeled compounds are not available, an internal standard method is used. Under the prescribed conditions, for both the labeled, and unlabeled ethylbenzene the method has a minimum detection level 10 ug/l.The established acceptance performance criteria at 20 ug/l is 6.2 ug/l for the standard deviation of the recovery, with the average recovery of 14.5 to 28.7 ug/l and the labeled cmpd recovery ranging from 4 to 193%.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 8020. Direct Injection or Purge-and-Trap Gas Chromatograpy with photoionization detection for the determination of aromatic volatile organics including **toluene** in solid waste. Under the prescribed conditions, for **toluene** the method has a detection limit of 0.2 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[USEPA; Test Methods for Evaluating Solid Waste SW-846 (1986)]**PEER REVIEWED**

EPA Method 8240. Gas Chromatography/Mass Spectrometry for the determination of volatile Organics. This method can be used to quantify most volatile organic compounds including **toluene** that have boiling points below 200 deg C and are insoluble or slightly soluble in water. The detection limit is not given. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[USEPA; Test Methods for Evaluating Solid Waste SW-846 (1986)]**PEER REVIEWED**

EPA Method 502.2: Purge-and-Trap Capillary Column Gas Chromatography with Photoionization and Electrolytic Conductivity Detectors in Series. The method is applicable for the determination of volatile organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For **toluene** the method has a detection limit of 0.01 ug/l, a percent recovery of 99%, and a standard deviation of 1.9 using the photoionization detector.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 502.1. Purge and Trap Gas Chromatography with a halogen-specific detector for the determination of halogenated volatile compounds including **toluene** in finished drinking water, raw source water, or drinking water in any treatment stage. Under the prescribed conditions for **toluene**, the method detection limit is 0.02 ug/l.

IN EXPERIMENTS IN VITRO, **TOLUENE** DID NOT CHANGE NUMBER OF SISTER-CHROMATID EXCHANGES OR THE NUMBER OF CHROMOSOMAL ABERRATIONS IN HUMAN LYMPHOCYTES.
[GERNER-SCMIDT P, FRIEDRICH U; MUTATION RESEARCH 58: 313 (1978)]**PEER REVIEWED**

A 28 yr old painter who was believed to be a habitual **toluene** sniffer was admitted to Chiba Emergency Medical Center on several occasions. Symptoms included: Tremors of the upper extremeties, staggering of gait, slurred speech, slight mental deterioration, pendular nystagmus, bradycardia, mild tremor of the leg, action myoclonus, and head and trunchal titubation. There was no dysmetria. The involuntary movements were classified as hyperkinesie volitionnelle. Muscle tone was hypotonic. Muscle weakness and atrophy were not seen. Deep tendon reflexes were all exaggerated, but there was no pathological reflex. He showed wide-based ataxic gait. Sensory and autonomic functions were normal. Blood, urine and cerebrospinal fluid analysis appeared normal. Electroencephalography showed 40-50 uV, 9-10 c/s alpha waves with a few fast waves. Brain CT scan revealed a moderate enlargement of the lateral and third ventricles. Surface electromyography was performed on the proximal musculature of the arm. 3 c/s reciprocal rhythmical grouping discharges were found at the terminal phase of the elbow bending. The tremor was diminished by 20 minutes ischemic compression test of the arm. With respect to therapy, clonazepam was useful for hyperkinesie volitionnelle. He became able to drink a cup of water without spilling it by his own hands, and was discharged from hospital on April 3rd, 1981. It was believed that he was a habitual sniffer to **toluene**. On June 30th, 1983 he was found comatose. On admission to Chiba

Emergency Medical Center, his breath smelt of **toluene**. His blood **toluene** level was 7.53 ppm, and urinary hippuric acid concentration was 9,500 mg/l. He died on July 9th, 1983, because of disseminated intravascular coagulation, multiple organ failure and perforation of the terminal ileum. Autopsy was performed and neuropathological findings were as follows. 1) Diffuse demyelination and gliosis of the cerebral and cerebella white matter. 2) Marked loss of Purkinje cells of the cerebellum. 3) Astrocytic proliferation of the dentate fugal system and inferior olivary nucleus of medulla. ...
[Arai K et al; Brain Nerve Tokyo 38 (12): 1181-86 (1986)]**PEER REVIEWED**

Autopsy findings on a man who fell from a height due to acute **toluene** poisoning while painting are described. Gas chromatographic examination revealed that the **toluene** concentrations of his blood, lung, liver and brain were 48, 35, 65 and 80 ug/g, respectively. These **toluene** levels were not enough to be definitely lethal, but were enough to anesthetize the central nervous system.
[Takeichi S et al; Forensic Sci Int 32 (2): 109-16 (1986)]**PEER REVIEWED**

The psychological performance of 43 rotogravure printers exposed to a mean time- weighted average of 117 ppm **toluene** for a mean time period of 21.7 yr was compared to that of 31 offset printers with a mean working period of 23 yr. The offset printers were exposed to mixtures of aliphatic hydrocarbons or ethyl acetate (amounts not given) for a total of 10 to 60 min daily. Drinking habits were considered in grouping the workers. The test battery consisted of standardized tests for verbal and visual cognition and memory, perceptual motor speed, and psychomotor abilities. Performances of the two printer groups were similar with rotogravure printers having statistically significant lower scores on tests measuring visual cognitive abilities. Mean test performances indicated that drinking habits did not explain the impairment of visual cognitive abilities.
[Hanninen H et al; Int Arch Occupat Environ Health 59 (5): 475-83 (1987)]**PEER REVIEWED**

Acute poisoning may result from exposure to high concn of **toluene**; A /CNS depressant/ effect is produced. Human death has resulted from exposure to 10,000 ppm. **Toluene** is more acutely toxic than benzene; however, severe blood disorders of the type associated with benzene are not reported. Inhalation of 200 ppm has affected the CNS in humans.
[Cleland, J.G., G.L. Kingsbury. Multimedia Environmental Goals for Environmental Assessment. Volume 1. EPA-600/7-77-136a. Research Triangle Park, NC: EPA, Nov. 1977.,p. E-146]**PEER REVIEWED**

Vapors irritate eyes and upper respiratory tract; Cause dizziness, headache, anesthesia, and respiratory arrest. Liquid irritates eyes. If aspirated, causes coughing, gagging, distress, and rapidly developing pulmonary edema. If ingested causes vomiting, griping, diarrhea, and depressed respiration. Kidney and liver damage may follow ingestion.
[U.S. Coast Guard, Department of Transportation. CHRIS - Hazardous Chemical Data. Volume II. Washington, D.C.: U.S. Government Printing Office, 1984-5.]**PEER REVIEWED**

In recent years some youngsters have been indulging in what is called thinner inhalation, posing a serious social problem. Organic solvents have also been widely used industrially as adhesives or degreasing and rinsing agents, generating a kind of occupational disease which has become a medical problem. Some

school children who refuse to go to school complaining of headache, head heaviness, blurred vision, diplopia, or dizziness, may actually have **toluene** toxicosis caused by the adhesive they use in constructing plastic models. /An examination of/ 35 such patients neurogically, found some impairment in the cerebellar cortex, cerebellar nuclei, or efferent pathways. This report is presented to invite comments from other researchers.
[Sakata E et al; Pract Otal Kyoto 79 (12): 1999-2013 (1986)]**PEER REVIEWED**

Severe, acute **toluene** intoxication in two workers was described. Special attention was paid to the metabolism of **toluene** in man and to the choice of reference parameters to monitor intoxication. The men had tiled a small swimming pool to be used for exercise programs in a rehabilitation clinic. They had used a special glue to make the joints of cement between the tiles resistant to bleaching solution; the next day they removed the excess glue using **toluene**. One worker was exposed for 2 hours and the other for 3 hours. Both were overcome with the fumes, and were found lying at the bottom of the pool. Symptoms included stupefaction, paresis, and amnesia. Patient-A had mucosal irritation of the eyes and slurred speech. He was stuporose and unable to walk or sit. His amnesia lasted for about 3 hours. Patient-B had mucosal irritation of the eyes, was drowsy, and was just able to walk. He had normal speech and complained of headache. The duration of his amnesia was about 2.5 hours. Solid evidence for **toluene** exposure was provided by the blood **toluene** concentration. The concentration 2 hours after exposure was 4.1 mg/l in patient-A and 2.2 mg/l in patient-B.
[Meulenbelt J et al; Br J Ind Med 47 (6): 417-20 (1990)]**PEER REVIEWED**

The memory sequelae for a group of female workers accidentally exposed to organic solvents were examined retrospectively to evaluate complaints of residual memory impairment. The subjects included seven employees (mean age 32.1 years) who agreed to retesting and who had been severely intoxicated by exposure to **toluene** and aliphatic hydrocarbons found in adhesives used in the manufacture of tennis balls. They were compared to eight workers (mean age 33.7 years) who were solvent exposed but not affected by the accident and ten workers (mean age 36.6 years) who had no exposure. Acute symptoms included faintness, nausea, vomiting, and headache. Complaints of impaired memory, personality changes, and loss of confidence persisted 8 months after exposure. Memory testing was first performed 2 months after exposure, with the follow up 6 months later to assess recovery. The three memory tasks included paired associate task, serial position task, and Brown-Peterson task. The subjects showed normal patterns of performance on tests of learning and short term and long term memory, but demonstrated marked difficulties when attention had to be divided between two resource competing tasks. The clearest evidence of impairment was observed in the Brown-Peterson task, where the acute group showed a significantly greater increase in word recall omission after periods of counting backwards in threes. The magnitude of the memory sequelae was not correlated with scores of self rated depression. It was concluded that solvent intoxication can cause neuropsychological sequelae lasting more than 8 months; memory tasks could prove useful in identifying memory impairment in other occupationally exposed groups.
[Stollery BT, Flindt MLH; Scand J Work, Environ, Health 14 (1): 45-8 (1988)]**PEER REVIEWED**

In a cross-sectional study of 181 male workers of a rotogravure printing plant, most of whom were exposed to **toluene** levels well above the GDR threshold limit values, 55 subjects revealed pathological liver screening values (activities of serum aspartate aminotransferase, alanine aminotransferase, gamma

glutamyltransferase; liver size). The differential diagnostic examination showed in 51 of these 55 subjects an association with competing factors such as alcohol abuse (78%) and overweight (40%), to a slight extent disorders of fat and carbohydrate metabolism and of the gallbladder. Drug intake did not play any role. The variance and regression analyses of the biochemical data have shown that alcohol significantly and considerably increases the activities of all three enzymes tested. Bodyweight had a similar, but less pronounced, significant effect. On the other hand, in subjects with a higher alcohol intake the activities of liver enzymes in highly **toluene** exposed subgroups were significantly and clearly lower than among slightly **toluene** exposed workers.
[Boewer C et al; Int Arch Occup Environ Health 60 (3): 181-6 (1988)]**PEER REVIEWED**

General health effects include lethality, growth, morbidity, liver and kidney damage and miscellaneous effects. Neurobehavioral effects include epidemiological and clinical findings, activity and sleep, performance and learning, electrophysiological effects. Evaluation and synthesis of data is included. It was concluded that low level exposure to **toluene** has its primary effect on the CNS. From a systematic or general point of view it is not clear what this effect is. Both depressant and excitatory effects (possibly concentration dependent) were reported as well as other kinds of results. Other health effects were not life threatening at any exposure level short of that producing lethality. Effects were reversible even at extremely high exposure levels for very long durations.
[Benignus VA; Neurotoxicol 2 (3): 567-88 (1981)]**PEER REVIEWED**

Toluene embryopathy is characterized by microcephaly, central nervous system dysfunction, attentional deficits and hyperactivity, developmental delay with greater language deficits, minor craniofacial and limb anomalies, and variable growth deficiency. Previously, three affected children, born to women who inhaled **toluene** regularly throughout pregnancy, have been reported. Two more cases are described emphasizing the importance of **toluene** as a potential human teratogen.
[Hersh JH; J Med Genet 26 (5): 333-7 (1989)]**PEER REVIEWED**

Neurobehavioral tests were undertaken by 30 female workers exposed to **toluene** and matched controls with low occupational exposure to **toluene**. The environmental air levels (TWA) of **toluene** was 88 ppm for the exposed workers and 13 ppm for the controls. The **toluene** in blood concentrations for the exposed workers was 1.25 mg/l and for the controls 0.16 mg/l. Statistically significant differences between workers exposed to **toluene** and controls in neurobehavioral tests measuring manual dexterity (grooved peg board), a visual scanning (trail making, visual reproduction, Benton visual retention, and digit symbol), and verbal memory (digit span) were observed. Further, the performance at each of these tests was related to time weighted average exposure concentrations of air **toluene**. The workers exposed to **toluene** had no clinical symptoms or signs. The question arises as to whether these impairments in neurobehavioral tests are reversible or whether they could be a forerunner of more severe damage.
[Foo SC et al; BR J Ind Med 47 (7): 480-4 (1990)]**PEER REVIEWED**

When compared with benzene, **toluene** has little to no effect on immunocompetence. However, it should be noted that **toluene** exposure effectively attenuates the immunotoxic effects of benzene (probably because of competition for metabolic enzymes).
[Klaassen, C.D., M.O. Amdur, Doull J. (eds.). Casarett and Doull's Toxicology. The Basic Science of Poisons. 5th ed. New York, NY: McGraw-Hill, 1995. 380]**PEER REVIEWED**

Neutral organic solvents such as ... **toluene** ... cause pain on contacting the eye, and examination after a generous splash of solvent shows dulling of the cornea. The epithelium will show punctate staining with fluorescein. The damage appears to be scattered loss of epithelial cells due to solution of some of the fats that occur in these cells.
[Klaassen, C.D., M.O. Amdur, Doull J. (eds.). Casarett and Doull's Toxicology. The Basic Science of Poisons. 5th ed. New York, NY: McGraw-Hill, 1995. 586]**PEER REVIEWED**

Toxicities associated with **toluene**: CNS depression, syncope, coma, cardiac arrhythmias and sudden death, ataxia, convulsions, rhabdomyolysis, increased creatine phosphokinase, abdominal pain, nausea, vomiting, hematemesis, peripheral neuropathy, paresthesias, encephalopathy, optic neuropathy, cerebella ataxia, distal renal tubular acidosis, hyperchloremia, hypokalemia, azotemia, hypophosphatemia, hematuria, proteinuria, pyruria, normalities, decreased cognitive function, fatal overdose. /From table/
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 1494]**PEER REVIEWED**

Women workers exposed to high air concentrations of **toluene** (50-150 ppm) appeared to have a higher incidence of spontaneous abortion than a similar group of women with no occupational exposure to **toluene**.
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 166]**PEER REVIEWED**

Maternal spray paint or glue sniffing leads to maternal complications including renal tubular acidosis, hypokalemia, hypocalcemia, cardiac arrhythmias, rhabdomyolysis, and premature labor. Premature **toluene** exposure leads to a characteristic pattern of anomalies similar to findings in infants exposed to alcohol in utero, consisting of an increased incidence of malformations, poor growth, and developmental delays.
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 166]**PEER REVIEWED**

Eye and upper airway irritation occurred after a 6.5 hr exposure to an air level of 100 ppm (377 mg/cu m) **toluene**, and lachrymation was seen at 500 mg/cu m.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 101 (1989)]**PEER REVIEWED**

Volunteers exposed to 100 ppm (377 mg/cu m) **toluene** for 6 hr/day for four days suffered from subjective complaints of headache, dizziness and a sensation of intoxication. In subjects exposed to 750 mg/cu m for 8 hr, fatigue, muscular weakness, confusion, impaired coordination, enlarged pupils and accommodation disturbances were experienced; at about 3000 mg/cu m, severe fatigue, pronounced nausea, mental confusion, considerable incoordination with staggering gait and strongly affected pupillary light reflexes were observed. After exposure at the high level, muscular fatigue, nervousness and insomnia lasted for several days. Heavy accidental exposure leads to coma.

[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 101 (1989)]**PEER REVIEWED**

Humans exposed to concentrations of **toluene** of between 200-800 ppm may experience respiratory and ocular irritation.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1090]**PEER REVIEWED**

Children with microcephaly, minor craniofacial and limb anomalies, central nervous system defects, attention disorders, developmental delay, learning disorders, and language deficits were born to mothers who abuse **toluene** by inhalation during pregnancy.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1091]**PEER REVIEWED**

Controlled exposure effects on volunteers were studied at **toluene** concentrations ranging from 40, 60, or 100 ppm. ... Psychologic measurements indicated decrements in vigilance, visual perception, motor performance, and ability to carry out functions at 100 ppm.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1092]**PEER REVIEWED**

Acute effects in humans following exposure to **toluene**: 50-100 ppm: subjective complaints (fatigue or headache), but probably no observable impairment of reaction time or coordination; 200 ppm: mild throat and eye irritation; 100-300 ppm: detectable signs of incoordination may be expected during exposure periods up to 8 hr; 400 ppm: lacrimation and irritation to the eyes and throat; 300-800 ppm: gross signs of incoordination may be expected during exposure periods up to 8 hr; 1500 ppm: probably not lethal for exposure periods of up to 8 hr; 4000 ppm: would probably cause rapid impairment of reaction time and coordination, exposures of one hr or longer might lead to /CNS depression/ and possibly death; 10,000-30,000 ppm: onset of /CNS depression/ within a few minutes, longer exposures may be lethal. /From table/

1571]**PEER REVIEWED**

Toluene abuse (to 10,000 ppm) has been linked with kidney disease as evidenced by blood (hematuria), protein (proteinuria), albumin (albuminuria), and pus (pyuria) in the urine, accompanied by elevated serum creatinine, decreased urinary output, and metabolic and renal tubular acidosis.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991.
1573]**PEER REVIEWED**

... The highest **toluene** concentrations in air that could be tolerated for 3.5-6 hr without measurable decrements on behavioral test performance were 80 ppm to 100 ppm.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991.
1574]**PEER REVIEWED**

The pregnancies of four of five women associated with gross **toluene** abuse (0.5 to 2 cans of spray paint/day for 6 mos to 11 yr) resulted in evidence of renal toxicity (as evidenced by severe renal tubular acidosis), fetal toxicity (manifest as intrauterine growth retardation), and teratogenicity (deformed external ears, ventricular septal defect, micrognathia, hydronephrosis) with facial features reminiscent of the FAS (short palpebral fissures, epicanthal folds, maxillary hypoplasia).
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991.
1575]**PEER REVIEWED**

In a case study of two adult white males who suffered from **toluene** intoxication while removing glue from tiles in a swimming pool, cardiac arrhythmias were noted. Response seemed to be highly variable among individuals. One person exposed for 2 hr to less than 1890 ppm **toluene** exhibited a rapid heartbeat (sinus tachycardia), while the second person, exposed for 3 hr, exhibited a slow heartbeat (bradycardia).
[Meulenbelt J et al; Br J Ind Med 47: 417-20 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.31 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Severe renal tubular acidosis was observed in five pregnant women who were chronic abusers of paints containing **toluene**.
[Goodwin TM; Obstet Gynecol 71: 715-18 (1988) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.36 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Exposure of students to 75 or 150 ppm **toluene** for 7 hr caused a dose-related impairment of function on digit span, pattern recognition, the one hole test, and pattern memory. There was an effect on the results of the symbol digit test but the effect was not dose related. Subjects served as their own controls. ... There were no differences in the results on simple reaction time, POMS mood scale, visual memory,

hand-eye coordination, Sternberg test, finger tapping, reaction time, continuous performance test, and critical tracking test.
[Echeverria D et al; Br J Ind Med 48: 750-61 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.40 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

A group of 95-104 workers exposed to TWA of 41-46 ppm **toluene** during shoemaking, printing, and audio equipment production were evaluated for symptoms and signs of exposure when compared to 130 control subjects. The incidence of health-related complaints among the **toluene** exposed workers was two to three times that of the controls. Dizziness was reported by about two-thirds of the **toluene** exposed respondents. These subjects also complained of headaches, sore throats, eye irritation, and difficulty with sleep. When the exposed subjects were divided into two groups, one with TWA exposures of less than 40 ppm and the other with exposures greater than or equal to 40 ppm, the incidence of headache and sore throat, but not dizziness, showed a dose-response pattern.
[Yin S et al; Ind Health 25: 113-30 (1987) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.41 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Children born to **toluene** abusers have exhibited renal tubular acidosis immediately after birth due to hyperchloremia. In each incident the acidosis was resolved within 3 days of birth.
[Lindemann R; Acta Pediatr Scand 80: 882-4 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.49 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Several case series have demonstrated that high exposure to **toluene** through sniffing during pregnancy induces a syndrome that closely resembles the fetal alcohol syndrome, with pre- and postnatal growth deficiency, microcephaly and developmental delay, typical craniofacial features including micrognathia, small palpebral fissures, and ear anomalies.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V71 845 (1999)]**PEER REVIEWED**

Renal tubular acidosis is one of a number of human complications reported in the offspring of mothers inhaling **toluene** during pregnancy. This article reports a case of a premature newborn with renal tubular acidosis probably due to maternal sniffing of paint containing **toluene**. Characteristics of this condition are described as well as its medical management.

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,625,598 workers (288,299 of these are female) are potentially exposed to **toluene** in the US(1). Occupational exposure to **toluene** may occur through inhalation and dermal contact with this compound at workplaces where **toluene** is produced or used(SRC). The general population may be exposed to **toluene** via inhalation of ambient air, ingestion of food and drinking water, handling of gasoline, and exposure to some consumer products where **toluene** is used as a solvent(SRC).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983)]**PEER REVIEWED**

Toluene was detected in hairdresser salons in Norway at concns of 0.04-0.11 mg/cu m(1). The time weighted average (TWA) of **toluene** in the workplace air of a municipal waste composting facility was reported as 188,000 ug/cu m(2). In a 1989 Danish survey on chemical exposures(3), the number of worker exposure events for **toluene** were documented: manufacturing of metals, 420; manufacturing of metal fabricated products 64,000; electrical machinery and apparatus, 1,500; manufacture of transport equipment 2,700; painters and carpenters 15,000; construction workers, 5,400; publishing and printing, 6,300; wholesale trades, 5,000; textile and leather manufacturing, 4,400; wood and furniture manufacturing, 5,900; manufacture of chemicals, 8,700; manufacture of paints and petroleum, 1,400; manufacture of non-metallic mineral products, 2,300; manufacture of optical instruments, 2,500

manufacture of plastic and boat building, 1,100; sewage and refuse disposal, 99; agriculture and forestry, 11,000; health services, 2,600. The total number of work related exposure events was 140,000(3). **Toluene** was detected in the workplace air of glass fiber manufacturing plants and high temperature sealing component and clutch lining plants at a mean concn of 65 ppm(4).

A 28 yr old painter who was believed to be a habitual **toluene** sniffer was admitted to Chiba Emergency Medical Center on several occasions. Symptoms included: Tremors of the upper extremeties, staggering of gait, slurred speech, slight mental deterioration, pendular nystagmus, bradycardia, mild tremor of the leg, action myoclonus, and head and trunchal titubation. There was no dysmetria. The involuntary movements were classified as hyperkinesie volitionnelle. Muscle tone was hypotonic. Muscle weakness and atrophy were not seen. Deep tendon reflexes were all exaggerated, but there was no pathological reflex. He showed wide-based ataxic gait. Sensory and autonomic functions were normal. Blood, urine and cerebrospinal fluid analysis appeared normal. Electroencephalography showed 40-50 uV, 9-10 c/s alpha waves with a few fast waves. Brain CT scan revealed a moderate enlargement of the lateral and third ventricles. Surface electromyography was performed on the proximal musculature of the arm. 3 c/s reciprocal rhythmical grouping discharges were found at the terminal phase of the elbow bending. The tremor was diminished by 20 minutes ischemic compression test of the arm. With respect to therapy, clonazepam was useful for hyperkinesie volitionnelle. He became able to drink a cup of water without spilling it by his own hands, and was discharged from hospital on April 3rd, 1981. It was believed that he was a habitual sniffer to **toluene**. On June 30th, 1983 he was found comatose. On admission to Chiba Emergency Medical Center, his breath smelt of **toluene**. His blood **toluene** level was 7.53 ppm, and urinary hippuric acid concentration was 9,500 mg/l. He died on July 9th, 1983, because of disseminated intravascular coagulation, multiple organ failure and perforation of the terminal ileum. Autopsy was performed and neuropathological findings were as follows. 1) Diffuse demyelination and gliosis of the cerebral and cerebella white matter. 2) Marked loss of Purkinje cells of the cerebellum. 3) Astrocytic proliferation of the dentate fugal system and inferior olivary nucleus of medulla. ...
[Arai K et al; Brain Nerve Tokyo 38 (12): 1181-86 (1986)]**PEER REVIEWED**

Autopsy findings on a man who fell from a height due to acute **toluene** poisoning while painting are described. Gas chromatographic examination revealed that the **toluene** concentrations of his blood, lung, liver and brain were 48, 35, 65 and 80 ug/g, respectively. These **toluene** levels were not enough to be definitely lethal, but were enough to anesthetize the central nervous system.
[Takeichi S et al; Forensic Sci Int 32 (2): 109-16 (1986)]**PEER REVIEWED**

The psychological performance of 43 rotogravure printers exposed to a mean time- weighted average of 117 ppm **toluene** for a mean time period of 21.7 yr was compared to that of 31 offset printers with a mean working period of 23 yr. The offset printers were exposed to mixtures of aliphatic hydrocarbons or ethyl acetate (amounts not given) for a total of 10 to 60 min daily. Drinking habits were considered in grouping the workers. The test battery consisted of standardized tests for verbal and visual cognition and memory, perceptual motor speed, and psychomotor abilities. Performances of the two printer groups were similar with rotogravure printers having statistically significant lower scores on tests measuring visual cognitive abilities. Mean test performances indicated that drinking habits did not explain the impairment of visual cognitive abilities.
[Hanninen H et al; Int Arch Occupat Environ Health 59 (5): 475-83

(1987)]**PEER REVIEWED**

Acute poisoning may result from exposure to high concn of **toluene**; A /CNS depressant/ effect is produced. Human death has resulted from exposure to 10,000 ppm. **Toluene** is more acutely toxic than benzene; however, severe blood disorders of the type associated with benzene are not reported. Inhalation of 200 ppm has affected the CNS in humans.
[Cleland, J.G., G.L. Kingsbury. Multimedia Environmental Goals for Environmental Assessment. Volume 1. EPA-600/7-77-136a. Research Triangle Park, NC: EPA, Nov. 1977.,p. E-146]**PEER REVIEWED**

Vapors irritate eyes and upper respiratory tract; Cause dizziness, headache, anesthesia, and respiratory arrest. Liquid irritates eyes. If aspirated, causes coughing, gagging, distress, and rapidly developing pulmonary edema. If ingested causes vomiting, griping, diarrhea, and depressed respiration. Kidney and liver damage may follow ingestion.
[U.S. Coast Guard, Department of Transportation. CHRIS - Hazardous Chemical Data. Volume II. Washington, D.C.: U.S. Government Printing Office, 1984-5.]**PEER REVIEWED**

In recent years some youngsters have been indulging in what is called thinner inhalation, posing a serious social problem. Organic solvents have also been widely used industrially as adhesives or degreasing and rinsing agents, generating a kind of occupational disease which has become a medical problem. Some school children who refuse to go to school complaining of headache, head heaviness, blurred vision, diplopia, or dizziness, may actually have **toluene** toxicosis caused by the adhesive they use in constructing plastic models. /An examination of/ 35 such patients neurogically, found some impairment in the cerebellar cortex, cerebellar nuclei, or efferent pathways. This report is presented to invite comments from other researchers.
[Sakata E et al; Pract Otal Kyoto 79 (12): 1999-2013 (1986)]**PEER REVIEWED**

Severe, acute **toluene** intoxication in two workers was described. Special attention was paid to the metabolism of **toluene** in man and to the choice of reference parameters to monitor intoxication. The men had tiled a small swimming pool to be used for exercise programs in a rehabilitation clinic. They had used a special glue to make the joints of cement between the tiles resistant to bleaching solution; the next day they removed the excess glue using **toluene**. One worker was exposed for 2 hours and the other for 3 hours. Both were overcome with the fumes, and were found lying at the bottom of the pool. Symptoms included stupefaction, paresis, and amnesia. Patient-A had mucosal irritation of the eyes and slurred speech. He was stuporose and unable to walk or sit. His amnesia lasted for about 3 hours. Patient-B had mucosal irritation of the eyes, was drowsy, and was just able to walk. He had normal speech and complained of headache. The duration of his amnesia was about 2.5 hours. Solid evidence for **toluene** exposure was provided by the blood **toluene** concentration. The concentration 2 hours after exposure was 4.1 mg/l in patient-A and 2.2 mg/l in patient-B.
[Meulenbelt J et al; Br J Ind Med 47 (6): 417-20 (1990)]**PEER REVIEWED**

The memory sequelae for a group of female workers accidentally exposed to organic solvents were examined retrospectively to evaluate complaints of residual memory impairment. The subjects included seven employees (mean age 32.1 years) who agreed to retesting and who had been severely intoxicated

by exposure to **toluene** and aliphatic hydrocarbons found in adhesives used in the manufacture of tennis balls. They were compared to eight workers (mean age 33.7 years) who were solvent exposed but not affected by the accident and ten workers (mean age 36.6 years) who had no exposure. Acute symptoms included faintness, nausea, vomiting, and headache. Complaints of impaired memory, personality changes, and loss of confidence persisted 8 months after exposure. Memory testing was first performed 2 months after exposure, with the follow up 6 months later to assess recovery. The three memory tasks included paired associate task, serial position task, and Brown-Peterson task. The subjects showed normal patterns of performance on tests of learning and short term and long term memory, but demonstrated marked difficulties when attention had to be divided between two resource competing tasks. The clearest evidence of impairment was observed in the Brown-Peterson task, where the acute group showed a significantly greater increase in word recall omission after periods of counting backwards in threes. The magnitude of the memory sequelae was not correlated with scores of self rated depression. It was concluded that solvent intoxication can cause neuropsychological sequelae lasting more than 8 months; memory tasks could prove useful in identifying memory impairment in other occupationally exposed groups.
[Stollery BT, Flindt MLH; Scand J Work, Environ, Health 14 (1): 45-8 (1988)]**PEER REVIEWED**

In a cross-sectional study of 181 male workers of a rotogravure printing plant, most of whom were exposed to **toluene** levels well above the GDR threshold limit values, 55 subjects revealed pathological liver screening values (activities of serum aspartate aminotransferase, alanine aminotransferase, gamma glutamyltransferase; liver size). The differential diagnostic examination showed in 51 of these 55 subjects an association with competing factors such as alcohol abuse (78%) and overweight (40%), to a slight extent disorders of fat and carbohydrate metabolism and of the gallbladder. Drug intake did not play any role. The variance and regression analyses of the biochemical data have shown that alcohol significantly and considerably increases the activities of all three enzymes tested. Bodyweight had a similar, but less pronounced, significant effect. On the other hand, in subjects with a higher alcohol intake the activities of liver enzymes in highly **toluene** exposed subgroups were significantly and clearly lower than among slightly **toluene** exposed workers.
[Boewer C et al; Int Arch Occup Environ Health 60 (3): 181-6 (1988)]**PEER REVIEWED**

General health effects include lethality, growth, morbidity, liver and kidney damage and miscellaneous effects. Neurobehavioral effects include epidemiological and clinical findings, activity and sleep, performance and learning, electrophysiological effects. Evaluation and synthesis of data is included. It was concluded that low level exposure to **toluene** has its primary effect on the CNS. From a systematic or general point of view it is not clear what this effect is. Both depressant and excitatory effects (possibly concentration dependent) were reported as well as other kinds of results. Other health effects were not life threatening at any exposure level short of that producing lethality. Effects were reversible even at extremely high exposure levels for very long durations.
[Benignus VA; Neurotoxicol 2 (3): 567-88 (1981)]**PEER REVIEWED**

Toluene embryopathy is characterized by microcephaly, central nervous system dysfunction, attentional deficits and hyperactivity, developmental delay with greater language deficits, minor craniofacial and limb anomalies, and variable growth deficiency. Previously, three affected children, born to women who inhaled **toluene** regularly throughout pregnancy, have been reported. Two more cases are described emphasizing the importance of **toluene** as a potential human teratogen.

[Hersh JH; J Med Genet 26 (5): 333-7 (1989)]**PEER REVIEWED**

Neurobehavioral tests were undertaken by 30 female workers exposed to **toluene** and matched controls with low occupational exposure to **toluene**. The environmental air levels (TWA) of **toluene** was 88 ppm for the exposed workers and 13 ppm for the controls. The **toluene** in blood concentrations for the exposed workers was 1.25 mg/l and for the controls 0.16 mg/l. Statistically significant differences between workers exposed to **toluene** and controls in neurobehavioral tests measuring manual dexterity (grooved peg board), a visual scanning (trail making, visual reproduction, Benton visual retention, and digit symbol), and verbal memory (digit span) were observed. Further, the performance at each of these tests was related to time weighted average exposure concentrations of air **toluene**. The workers exposed to **toluene** had no clinical symptoms or signs. The question arises as to whether these impairments in neurobehavioral tests are reversible or whether they could be a forerunner of more severe damage.
[Foo SC et al; BR J Ind Med 47 (7): 480-4 (1990)]**PEER REVIEWED**

When compared with benzene, **toluene** has little to no effect on immunocompetence. However, it should be noted that **toluene** exposure effectively attenuates the immunotoxic effects of benzene (probably because of competition for metabolic enzymes).
[Klaassen, C.D., M.O. Amdur, Doull J. (eds.). Casarett and Doull's Toxicology. The Basic Science of Poisons. 5th ed. New York, NY: McGraw-Hill, 1995. 380]**PEER REVIEWED**

Neutral organic solvents such as ... **toluene** ... cause pain on contacting the eye, and examination after a generous splash of solvent shows dulling of the cornea. The epithelium will show punctate staining with fluorescein. The damage appears to be scattered loss of epithelial cells due to solution of some of the fats that occur in these cells.
[Klaassen, C.D., M.O. Amdur, Doull J. (eds.). Casarett and Doull's Toxicology. The Basic Science of Poisons. 5th ed. New York, NY: McGraw-Hill, 1995. 586]**PEER REVIEWED**

Toxicities associated with **toluene**: CNS depression, syncope, coma, cardiac arrhythmias and sudden death, ataxia, convulsions, rhabdomyolysis, increased creatine phosphokinase, abdominal pain, nausea, vomiting, hematemesis, peripheral neuropathy, paresthesias, encephalopathy, optic neuropathy, cerebella ataxia, distal renal tubular acidosis, hyperchloremia, hypokalemia, azotemia, hypophosphatemia, hematuria, proteinuria, pyruria, normalities, decreased cognitive function, fatal overdose. /From table/
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 1494]**PEER REVIEWED**

Women workers exposed to high air concentrations of **toluene** (50-150 ppm) appeared to have a higher incidence of spontaneous abortion than a similar group of women with no occupational exposure to **toluene**.
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 166]**PEER REVIEWED**

Maternal spray paint or glue sniffing leads to maternal complications including renal tubular acidosis, hypokalemia, hypocalcemia, cardiac arrhythmias, rhabdomyolysis, and premature labor. Premature **toluene** exposure leads to a characteristic pattern of anomalies similar to findings in infants exposed to

alcohol in utero, consisting of an increased incidence of malformations, poor growth, and developmental delays.
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 166]**PEER REVIEWED**

Eye and upper airway irritation occurred after a 6.5 hr exposure to an air level of 100 ppm (377 mg/cu m) **toluene**, and lachrymation was seen at 500 mg/cu m.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 101 (1989)]**PEER REVIEWED**

Volunteers exposed to 100 ppm (377 mg/cu m) **toluene** for 6 hr/day for four days suffered from subjective complaints of headache, dizziness and a sensation of intoxication. In subjects exposed to 750 mg/cu m for 8 hr, fatigue, muscular weakness, confusion, impaired coordination, enlarged pupils and accommodation disturbances were experienced; at about 3000 mg/cu m, severe fatigue, pronounced nausea, mental confusion, considerable incoordination with staggering gait and strongly affected pupillary light reflexes were observed. After exposure at the high level, muscular fatigue, nervousness and insomnia lasted for several days. Heavy accidental exposure leads to coma.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 101 (1989)]**PEER REVIEWED**

Humans exposed to concentrations of **toluene** of between 200-800 ppm may experience respiratory and ocular irritation.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1090]**PEER REVIEWED**

Children with microcephaly, minor craniofacial and limb anomalies, central nervous system defects, attention disorders, developmental delay, learning disorders, and language deficits were born to mothers who abuse **toluene** by inhalation during pregnancy.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1091]**PEER REVIEWED**

Controlled exposure effects on volunteers were studied at **toluene** concentrations ranging from 40, 60, or 100 ppm. ... Psychologic measurements indicated decrements in vigilance, visual perception, motor performance, and ability to carry out functions at 100 ppm.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1092]**PEER REVIEWED**

Acute effects in humans following exposure to **toluene**: 50-100 ppm: subjective complaints (fatigue or headache), but probably no observable impairment of reaction time or coordination; 200 ppm: mild throat and eye irritation; 100-300 ppm: detectable signs of incoordination may be expected during

exposure periods up to 8 hr; 400 ppm: lacrimation and irritation to the eyes and throat; 300-800 ppm: gross signs of incoordination may be expected during exposure periods up to 8 hr; 1500 ppm: probably not lethal for exposure periods of up to 8 hr; 4000 ppm: would probably cause rapid impairment of reaction time and coordination, exposures of one hr or longer might lead to /CNS depression/ and possibly death; 10,000-30,000 ppm: onset of /CNS depression/ within a few minutes, longer exposures may be lethal. /From table/
[Zenz, C., O.B. Dickerson, E.P. Horvath. Occupational Medicine. 3rd ed. St. Louis, MO., 1994 724]**PEER REVIEWED**

Studies of women exposed to solvents such as benzene, **toluene**, and xylene have shown menstrual disturbances, principally associated with abnormal bleeding.
[Rom, W.N. (ed.). Environmental and Occupational Medicine. 2nd ed. Boston, MA: Little, Brown and Company, 1992. 155]**PEER REVIEWED**

FROM THE STANDPOINT OF CHRONIC EXPOSURE, IT IS CLEAR THAT **TOLUENE** DOES NOT CAUSE THE SEVERE INJURY TO THE BONE MARROW THAT IS CHARACTERISTIC OF BENZENE POISONING.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 1571]**PEER REVIEWED**

Toluene abuse (to 10,000 ppm) has been linked with kidney disease as evidenced by blood (hematuria), protein (proteinuria), albumin (albuminuria), and pus (pyuria) in the urine, accompanied by elevated serum creatinine, decreased urinary output, and metabolic and renal tubular acidosis.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 1573]**PEER REVIEWED**

... The highest **toluene** concentrations in air that could be tolerated for 3.5-6 hr without measurable decrements on behavioral test performance were 80 ppm to 100 ppm.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 1574]**PEER REVIEWED**

The pregnancies of four of five women associated with gross **toluene** abuse (0.5 to 2 cans of spray paint/day for 6 mos to 11 yr) resulted in evidence of renal toxicity (as evidenced by severe renal tubular acidosis), fetal toxicity (manifest as intrauterine growth retardation), and teratogenicity (deformed external ears, ventricular septal defect, micrognathia, hydronephrosis) with facial features reminiscent of the FAS (short palpebral fissures, epicanthal folds, maxillary hypoplasia).
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 1575]**PEER REVIEWED**

In a case study of two adult white males who suffered from **toluene** intoxication while removing glue

from tiles in a swimming pool, cardiac arrhythmias were noted. Response seemed to be highly variable among individuals. One person exposed for 2 hr to less than 1890 ppm **toluene** exhibited a rapid heartbeat (sinus tachycardia), while the second person, exposed for 3 hr, exhibited a slow heartbeat (bradycardia).
[Meulenbelt J et al; Br J Ind Med 47: 417-20 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.31 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Severe renal tubular acidosis was observed in five pregnant women who were chronic abusers of paints containing **toluene**.
[Goodwin TM; Obstet Gynecol 71: 715-18 (1988) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.36 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Exposure of students to 75 or 150 ppm **toluene** for 7 hr caused a dose-related impairment of function on digit span, pattern recognition, the one hole test, and pattern memory. There was an effect on the results of the symbol digit test but the effect was not dose related. Subjects served as their own controls. ... There were no differences in the results on simple reaction time, POMS mood scale, visual memory, hand-eye coordination, Sternberg test, finger tapping, reaction time, continuous performance test, and critical tracking test.
[Echeverria D et al; Br J Ind Med 48: 750-61 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.40 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

A group of 95-104 workers exposed to TWA of 41-46 ppm **toluene** during shoemaking, printing, and audio equipment production were evaluated for symptoms and signs of exposure when compared to 130 control subjects. The incidence of health-related complaints among the **toluene** exposed workers was two to three times that of the controls. Dizziness was reported by about two-thirds of the **toluene** exposed respondents. These subjects also complained of headaches, sore throats, eye irritation, and difficulty with sleep. When the exposed subjects were divided into two groups, one with TWA exposures of less than 40 ppm and the other with exposures greater than or equal to 40 ppm, the incidence of headache and sore throat, but not dizziness, showed a dose-response pattern.
[Yin S et al; Ind Health 25: 113-30 (1987) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.41 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Children born to **toluene** abusers have exhibited renal tubular acidosis immediately after birth due to hyperchloremia. In each incident the acidosis was resolved within 3 days of birth.
[Lindemann R; Acta Pediatr Scand 80: 882-4 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.49 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Several case series have demonstrated that high exposure to **toluene** through sniffing during pregnancy induces a syndrome that closely resembles the fetal alcohol syndrome, with pre- and postnatal growth deficiency, microcephaly and developmental delay, typical craniofacial features including micrognathia, small palpebral fissures, and ear anomalies.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V71 845 (1999)]**PEER REVIEWED**

Renal tubular acidosis is one of a number of human complications reported in the offspring of mothers inhaling **toluene** during pregnancy. This article reports a case of a premature newborn with renal tubular acidosis probably due to maternal sniffing of paint containing **toluene**. Characteristics of this condition are described as well as its medical management.

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,625,598 workers (288,299 of these are female) are potentially exposed to **toluene** in the US(1). Occupational exposure to **toluene** may occur through inhalation and dermal contact with this compound at workplaces where **toluene** is produced or used(SRC). The general population may be exposed to **toluene** via inhalation of ambient air, ingestion of food and drinking water, handling of gasoline, and exposure to some consumer products where **toluene** is used as a solvent(SRC).

[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983)]**PEER REVIEWED**

Toluene was detected in hairdresser salons in Norway at concns of 0.04-0.11 mg/cu m(1). The time weighted average (TWA) of **toluene** in the workplace air of a municipal waste composting facility was reported as 188,000 ug/cu m(2). In a 1989 Danish survey on chemical exposures(3), the number of worker exposure events for **toluene** were documented: manufacturing of metals, 420; manufacturing of metal fabricated products 64,000; electrical machinery and apparatus, 1,500; manufacture of transport equipment 2,700; painters and carpenters 15,000; construction workers, 5,400; publishing and printing, 6,300; wholesale trades, 5,000; textile and leather manufacturing, 4,400; wood and furniture manufacturing, 5,900; manufacture of chemicals, 8,700; manufacture of paints and petroleum, 1,400; manufacture of non-metallic mineral products, 2,300; manufacture of optical instruments, 2,500 manufacture of plastic and boat building, 1,100; sewage and refuse disposal, 99; agriculture and forestry, 11,000; health services, 2,600. The total number of work related exposure events was 140,000(3). **Toluene** was detected in the workplace air of glass fiber manufacturing plants and high temperature sealing component and clutch lining plants at a mean concn of 65 ppm(4).

    have been instituted.
```

Clinical Effects:

```
SUMMARY OF EXPOSURE
 0.2.1.1 ACUTE EXPOSURE
   o   ACUTE INGESTION -
    1.  Causes CNS depression, oropharyngeal and gastric pain,
        vomiting.
   o   ACUTE INHALATION -
    1.  Causes CNS excitation followed by CNS depression and
        nausea.  Ataxia, fatigue, seizures and general
        anesthesia occur at high concentrations.
   o   CHRONIC INHALATION -
    1.  SYNDROMES - Muscular weakness, gastroenteritis, renal
        tubular acidosis, and neuropsychiatric syndrome are
        common in toluene sniffers.
    2.  EFFECTS - may include hypokalemia, hematuria,
        proteinuria, oliguria, paresis, rhabdomyolysis,
        hallucinations, hyperactive reflexes, peripheral
        neuropathy, personality changes, tremors, headaches,
        emotional lability, memory loss.
    3.  SEQUELAE - Progressive, irreversible encephalopathy
        with cognitive difficulty and cerebellar ataxia, and
        organic affective syndromes have been described.
   o   EYE EXPOSURE -
    1.  Blepharospasm, conjunctivitis, corneal edema, and
```

corneal abrasions usually resolve over 1-2 days.

- DERMAL EXPOSURE -

1. Prolonged or repeated dermal exposure to the liquid may defat the skin.

VITAL SIGNS

0.2.3.1 ACUTE EXPOSURE

- Bradycardia, hypotension and hypoventilation are rare effects.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Eye exposure causes irritation and superficial injury. Chronic abuse associated with decreased visual acuity, impaired color vision, optic atrophy, and ototoxicity.

CARDIOVASCULAR

0.2.5.1 ACUTE EXPOSURE

- ACUTE INHALATION - may cause dysrhythmias (usually in chronic abusers). Bradycardia, ventricular fibrillation, and myocardial infarction have been reported.
- CHRONIC INHALATION - Chronic sniffers may develop dysrhythmias, including PVCs and supraventricular tachycardia; dilated cardiomyopathy has been reported.
- ACUTE INGESTION may cause tachycardia and hypertension.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Inhalation may cause irritation, acute bronchitis, bronchospasm, pulmonary edema, pneumonitis, and asphyxia. Chronic abusers may develop respiratory failure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- ACUTE INGESTION - **Toluene** ingestion causes CNS depression.
- ACUTE INHALATION - 400 to 800 ppm: Euphoria, giddiness, tremors, nervousness, insomnia, headache, dizziness, fatigue, drowsiness, confusion, vertigo, increased reaction time; 800 ppm: ataxia, fatigue, seizures. 10,000 ppm: general anesthesia.
- CHRONIC INHALATION may cause hyperactive reflexes, peripheral neuropathy, personality changes, tremors, headaches, emotional lability, cognitive dysfunction, memory loss.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Ingestion or inhalation may cause vomiting, abdominal

cramps, and diarrhea.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Rarely hepatorenal failure has been attributed to **toluene** abuse or occupational exposure. Hepatomegaly and impaired liver function has also been reported.

GENITOURINARY

0.2.10.1 ACUTE EXPOSURE

- Transient distal renal tubular acidosis (RTA), with hyperchloremic metabolic acidosis, hypokalemia, and urine pH >5.5, is common in hospitalized paint sniffers. negative.
- Proximal RTA or Fanconi's syndrome is less common (urine pH >5.5, uricosuria, hypophosphatemia, hypocalcemia).
- Isolated cases of irreversible renal insufficiency, glomerulonephritis, focal segmental glomerulosclerosis, acute interstitial nephritis, and renal failure secondary to myoglobinuria have been reported.

ACID-BASE

0.2.11.1 ACUTE EXPOSURE

- Hyperchloremic metabolic acidosis common in hospitalized **toluene** abusers.

FLUID-ELECTROLYTE

0.2.12.1 ACUTE EXPOSURE

- Hypokalemia, metabolic acidosis, and hypophosphatemia are typical; hypercalcemia and hypouricemia less frequent. Hypocalcemia and precipitation of tetany has occurred during correction of acidemia.
- Patients with weakness may have severe fluid/electrolyte imbalance.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Prolonged contact may cause drying and defatting or superficial burns.

MUSCULOSKELETAL

0.2.15.1 ACUTE EXPOSURE

- Rhabdomyolysis is common in chronic **toluene** abusers. Severe muscle weakness is a common presentation in chronic abuse.

PSYCHIATRIC

0.2.18.1 ACUTE EXPOSURE

- Psychiatric disorders are common in chronic **toluene** abusers; including bizarre behavior, acute paranoid psychosis, confusion, visual and auditory hallucinations, mood lability, and decreased IQ.

REPRODUCTIVE HAZARDS

- Multiple physical deformities, with signs similar to fetal alcohol syndrome, microencephaly, CNS dysfunction, and variable growth deficiencies have occurred in infants born to mothers who abused **toluene** during pregnancy.

GENOTOXICITY

- There is conflicting information in the literature regarding the potential of **toluene** to cause DNA strand breaks. **Toluene** was not mutagenic in the Ames assay. Chromosome damage has been reported.

Laboratory:

- **Toluene** may be measured in the breath and blood; hippuric acid and cresol metabolites may be measured in the urine.
- Obtain a baseline CBC and monitor renal and hepatic function tests, urinalysis (including urine pH) electrolytes, and CPK. Monitor arterial blood gases in symptomatic patients.

Treatment Overview:

ORAL EXPOSURE

- EMESIS - Emesis is probably not indicated due to the possibility for aspiration of gastric contents.
- GASTRIC LAVAGE may be indicated when the patient has ingested a large quantity of **toluene**, or there is a large amount of benzene contamination, and emesis is contraindicated (obtunded, comatose, convulsing). The potential toxicity of the amount ingested must be weighed against the substantial risk of aspiration.

1. GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.

a. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.

- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12

years), and 1 g/kg in infants less than 1 year old.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with intravenous potassium.
- MONITOR PATIENT for RESPIRATORY DISTRESS.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.
- CHRONIC EXPOSURE - Evaluate renal and liver function.

INHALATION EXPOSURE
- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with potassium. CAUTION - Hypocalcemia may ensue following fluid and electrolyte replenishment.
- MONITOR for RESPIRATORY DISTRESS, assure airway patency and adequacy of ventilation and oxygenation.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.

EYE EXPOSURE
- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE
- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Ingestion - 60 mL lethal in an adult. Inhalation - 600 to 800 ppm for 3 hrs caused fatigue, nausea, confusion, ataxia; 10,000 ppm causes general anesthesia.

[Rumack BH: POISINDEX(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001. Hall AH & Rumack BH (Eds):TOMES(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001.]
PEER REVIEWED

Antidote and Emergency Treatment:

Basic treatment: Establish a patent airway. Suction if necessary. Watch for signs of respiratory insufficiency and assist ventilations if necessary. Administer oxygen by nonrebreather mask at 10 to 15 L/min. Monitor for pulmonary edema and treat if necessary ... . Monitor for shock and treat if necessary ... . For eye contamination, flush eyes immediately with water. Irrigate each eye continuously with normal saline during transport ... . Do not use emetics. For ingestion, rinse mouth and administer 5 ml/kg up to 200 ml of water for dilution if the patient can swallow, has a strong gag reflex, and does not drool. Administer activated charcoal ... . /Aromatic hydrocarbons and related compounds/
[Bronstein, A.C., P.L. Currance; Emergency Care for Hazardous Materials Exposure. 2nd ed. St. Louis, MO. Mosby Lifeline. 1994.,p. 181-2]**PEER REVIEWED**

Advanced treatment: Consider orotracheal or nasotracheal intubation for airway control in the patient who is unconscious or in respiratory arrest. Positive-pressure ventilation techniques with a bag-valve-mask device may be beneficial. Monitor cardiac rhythm and treat arrhythmias if necessary ... . Start an IV with D5W /SRP: "To keep open", minimal flow rate/. Use lactated Ringer's if signs of hypovolemia are present. Watch for signs of fluid overload. Consider drug therapy for pulmonary edema ... . Treat seizures with diazepam (Valium) ... . Use proparacaine hydrochloride to assist eye irrigation ... . /Aromatics hydrocarbons and related compounds/

Life Support:

```
o   This overview assumes that basic life support measures
    have been instituted.
```

Clinical Effects:

```
SUMMARY OF EXPOSURE
 0.2.1.1 ACUTE EXPOSURE
   o   ACUTE INGESTION -
    1.  Causes CNS depression, oropharyngeal and gastric pain,
        vomiting.
   o   ACUTE INHALATION -
    1.  Causes CNS excitation followed by CNS depression and
        nausea.  Ataxia, fatigue, seizures and general
        anesthesia occur at high concentrations.
   o   CHRONIC INHALATION -
    1.  SYNDROMES - Muscular weakness, gastroenteritis, renal
        tubular acidosis, and neuropsychiatric syndrome are
        common in toluene sniffers.
    2.  EFFECTS - may include hypokalemia, hematuria,
        proteinuria, oliguria, paresis, rhabdomyolysis,
        hallucinations, hyperactive reflexes, peripheral
        neuropathy, personality changes, tremors, headaches,
        emotional lability, memory loss.
    3.  SEQUELAE - Progressive, irreversible encephalopathy
        with cognitive difficulty and cerebellar ataxia, and
        organic affective syndromes have been described.
   o   EYE EXPOSURE -
    1.  Blepharospasm, conjunctivitis, corneal edema, and
        corneal abrasions usually resolve over 1-2 days.
   o   DERMAL EXPOSURE -
```

1. Prolonged or repeated dermal exposure to the liquid may defat the skin.

VITAL SIGNS

0.2.3.1 ACUTE EXPOSURE

- Bradycardia, hypotension and hypoventilation are rare effects.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Eye exposure causes irritation and superficial injury. Chronic abuse associated with decreased visual acuity, impaired color vision, optic atrophy, and ototoxicity.

CARDIOVASCULAR

0.2.5.1 ACUTE EXPOSURE

- ACUTE INHALATION - may cause dysrhythmias (usually in chronic abusers). Bradycardia, ventricular fibrillation, and myocardial infarction have been reported.
- CHRONIC INHALATION - Chronic sniffers may develop dysrhythmias, including PVCs and supraventricular tachycardia; dilated cardiomyopathy has been reported.
- ACUTE INGESTION may cause tachycardia and hypertension.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Inhalation may cause irritation, acute bronchitis, bronchospasm, pulmonary edema, pneumonitis, and asphyxia. Chronic abusers may develop respiratory failure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- ACUTE INGESTION - **Toluene** ingestion causes CNS depression.
- ACUTE INHALATION - 400 to 800 ppm: Euphoria, giddiness, tremors, nervousness, insomnia, headache, dizziness, fatigue, drowsiness, confusion, vertigo, increased reaction time; 800 ppm: ataxia, fatigue, seizures. 10,000 ppm: general anesthesia.
- CHRONIC INHALATION may cause hyperactive reflexes, peripheral neuropathy, personality changes, tremors, headaches, emotional lability, cognitive dysfunction, memory loss.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Ingestion or inhalation may cause vomiting, abdominal cramps, and diarrhea.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Rarely hepatorenal failure has been attributed to **toluene** abuse or occupational exposure. Hepatomegaly and impaired liver function has also been reported.

GENITOURINARY

0.2.10.1 ACUTE EXPOSURE

- Transient distal renal tubular acidosis (RTA), with hyperchloremic metabolic acidosis, hypokalemia, and urine pH >5.5, is common in hospitalized paint sniffers. negative.
- Proximal RTA or Fanconi's syndrome is less common (urine pH >5.5, uricosuria, hypophosphatemia, hypocalcemia).
- Isolated cases of irreversible renal insufficiency, glomerulonephritis, focal segmental glomerulosclerosis, acute interstitial nephritis, and renal failure secondary to myoglobinuria have been reported.

ACID-BASE

0.2.11.1 ACUTE EXPOSURE

- Hyperchloremic metabolic acidosis common in hospitalized **toluene** abusers.

FLUID-ELECTROLYTE

0.2.12.1 ACUTE EXPOSURE

- Hypokalemia, metabolic acidosis, and hypophosphatemia are typical; hypercalcemia and hypouricemia less frequent. Hypocalcemia and precipitation of tetany has occurred during correction of acidemia.
- Patients with weakness may have severe fluid/electrolyte imbalance.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Prolonged contact may cause drying and defatting or superficial burns.

MUSCULOSKELETAL

0.2.15.1 ACUTE EXPOSURE

- Rhabdomyolysis is common in chronic **toluene** abusers. Severe muscle weakness is a common presentation in chronic abuse.

PSYCHIATRIC

0.2.18.1 ACUTE EXPOSURE

- Psychiatric disorders are common in chronic **toluene** abusers; including bizarre behavior, acute paranoid psychosis, confusion, visual and auditory hallucinations, mood lability, and decreased IQ.

REPRODUCTIVE HAZARDS

- Multiple physical deformities, with signs similar to fetal alcohol syndrome, microencephaly, CNS dysfunction,

and variable growth deficiencies have occurred in infants born to mothers who abused **toluene** during pregnancy.

GENOTOXICITY

- There is conflicting information in the literature regarding the potential of **toluene** to cause DNA strand breaks. **Toluene** was not mutagenic in the Ames assay. Chromosome damage has been reported.

Laboratory:

- **Toluene** may be measured in the breath and blood; hippuric acid and cresol metabolites may be measured in the urine.
- Obtain a baseline CBC and monitor renal and hepatic function tests, urinalysis (including urine pH) electrolytes, and CPK. Monitor arterial blood gases in symptomatic patients.

Treatment Overview:

ORAL EXPOSURE

- EMESIS - Emesis is probably not indicated due to the possibility for aspiration of gastric contents.
- GASTRIC LAVAGE may be indicated when the patient has ingested a large quantity of **toluene**, or there is a large amount of benzene contamination, and emesis is contraindicated (obtunded, comatose, convulsing). The potential toxicity of the amount ingested must be weighed against the substantial risk of aspiration.

1. GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
   a. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.

- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with intravenous potassium.

- MONITOR PATIENT for RESPIRATORY DISTRESS.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.
- CHRONIC EXPOSURE - Evaluate renal and liver function.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- MONITOR FLUID and ELECTROLYTE STATUS CAREFULLY. Correct hypokalemia with potassium. CAUTION - Hypocalcemia may ensue following fluid and electrolyte replenishment.
- MONITOR for RESPIRATORY DISTRESS, assure airway patency and adequacy of ventilation and oxygenation.
- MONITOR EKG and VITAL SIGNS REGULARLY. Use epinephrine cautiously if indicated.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Ingestion - 60 mL lethal in an adult. Inhalation - 600 to 800 ppm for 3 hrs caused fatigue, nausea, confusion, ataxia; 10,000 ppm causes general anesthesia.

... Groups of rats were trained on the conditioned avoidance response task during the last week of a 5 week exposure to 1400 or 1200 ppm **toluene** (14 hr/day, 7 days/week) or during the first or third weeks after the exposure ended. None of the three groups ... were able to acquire the auditory condition avoidance response ... . Subsequent tests ... revealed that hearing with these rats was unimpaired at 4 KHz, slightly impaired at 8 KHz, and markedly impaired at 12 KHz and above.
[Pryor GT et al; Neurobehav Toxicol Terat 5 (1): 53-7 (1983)]**PEER REVIEWED**

Pregnant CD-1 mice were housed singly in multicompartment cages in inhalation chambers and exposed to **toluene** at a concentration of 0, 750, or 1500 mg/cu m (0, 200, or 400 ppm) for 7 hrs/day from day 7 through day 16 of gestation. The mice were killed on day 17 of gestation and the fetuses were removed and examined. Maternal weight gain was not affected by **toluene** exposure but the liver to body weight ratio was significantly reduced. The treated dams showed no significant differences in the average number of implantation sites, number of live fetuses, fetal mortality, or fetal body weight at either **toluene** concentration compared to control values. The incidence of enlarged renal pelvis was significantly greater in fetuses exposed to 200 ppm than in the fetuses exposed to 400 ppm or in the controls. A shift in rib profile (number of fetuses with 13 ribs) was observed in the higher **toluene** concentration group, and this shift was significantly different from the rib profile of controls. There was an increase in the total activity of lactic dehydrogenase activity in the brain of the dams from the 400 ppm group. The total activity of lactic dehydrogenase in the **toluene** exposed pups did not differ significantly from the controls for liver, heart, lung, or kidney, but the brain lactic dehydrogenase activity

of the treated group was slightly greater than the control value.
[Courtney KD et al; Fundam Appl Toxicol 6: 145-54 (1986)]**PEER REVIEWED**

Behavioral toxicity of **toluene** was assessed in mice confined in a 20 liter hermetically sealed chamber for several hours. **Toluene** was introduced through a port and volatilized by a hot plate. Samples of chamber air for analysis were taken through another port. A smaller mesh cage held the mouse within the larger chamber. Schedule-controlled responding was developed by arranging that a response, breaking a beam of light, was followed by mild (under an F1 60 sec) schedule. Responding was much more rapid in the presence of stimuli correlated with the F1 schedule than when the schedule was not operating. Standard sessions consisted of alternating series of 8 consecutive F1 60 sec and inter-series 30 min time-outs. Concentration-effect curves were determined by exposing a mouse to incremental additions of **toluene** at 30 min intervals. **Toluene** increased the rate of responding in most mice at levels of about 700 ppm. Higher concentrations progressively reduced responding. The ED50 (the concentration reducing responding by 50%) averaged 1657 ppm in 10 mice. It is estimated that there is a 1/1000 chance /ED001/ of the responding of a mouse being reduced by as much as 10% by a concentration of **toluene** of 69 ppm.
[Glowa JR et al; J Environ Pathol Toxicol Oncol 6 (5-6): 153-68 (1986)]**PEER REVIEWED**

Sixteen rats were chronically implanted with bipolar electrodes in the hipocampal regions containing cells generating electric theta-activity. The animals were divided into 4 groups of which 2 were exposed to 500 ppm of **toluene** in inhalation chambers, for 8 or 16 hours per day for 5 days per week in 12 weeks respectively, and 2 served as controls. The hippocampal electric activity was recorded 48 hours after each weekly exposure. Frequencies of theta-activity in the exposed groups were found to differ from their respective control group by variance analysis. Each point on the frequency versus time plot were further analysed by Student's t-test. Compared to the non-exposed group the eight hours daily exposed showed an initial period of increased frequency of the regular theta-waves together with an increased incidence of theta-activity after 1-2 weeks of exposure. In the sixteen hours daily exposed rats two weeks of **toluene** inhalation produced a significant reduction in the theta-wave frequency. This change was also reached after either weeks of exposure in the eight hours daily exposed group. At this moment the theta-activity was frequency disrupted by short amplitude irregular waves, a phenomen which increased gradually throughout the rest of the exposure period. The average blood concentration of **toluene** was 16.7 ug/ml and 17.7 ug/ml and not significantly different for the eight and sixteen hours exposed groups respectively.
[Naalsund LU; Acta Pharmacol Toxicol 59 (4): 325-31 (1988)]**PEER REVIEWED**

The effects of **toluene** vapors on brain lipid changes were investigated in male Sprague-Dawley rats. The animals (8/group) were continuously exposed to 320 ppm **toluene** for 30 days. Controls were exposed to air. Exposed animals showed decreased body weight ($p< 0.01$), decreased brain weight ($p< 0.01$), and a decrease in the weight of the cerebral cortex ($p< 0.05$) when compared to controls. In the cerebral cortex of exposed rats, total phospholipids was reduced ($p< 0.001$), there was an increase in phosphatidic acid ($p< 0.05$) and a decrease in a minor fatty acid of ethanolamine phosphoglyceride ($p< 0.05$). No changes in lipids were found in the brain stem.
[Kyrklund T et al; Toxicology 45: 123-33 (1987)]**PEER REVIEWED**

With the intention of investigating possible morphological alterations effected by **toluene** in the

developing CNS, rat pups were exposed to 100 ppm and 500 ppm of atmospheric **toluene** from postnatal day 1 until sacrifice at postnatal day 28, when the hippocampal region (area dentata, Ammon's horn, subiculum) was examined by light microscope and alterations in the volumes of the layers of the subdivisions were determined. The layers of Ammon's horn and the subiculum were not affected qualitatively or quantitatively by the 500 ppm exposure. Within the area dentata, the volume of the granule cell layer was 6% smaller in animals exposed to 100 ppm and 13% smaller in animals exposed to 500 ppm than they were in controls. The volumes of the hilus, which is a terminal field of granule cell axons, and the commissural-association zone of the dentate molecular layer, which is the terminal field of the hilar projection to the granule cells, were smaller (12% and 19%) in animals exposed to 500 ppm than they were in controls. Argyrophilic cells were found in the granule cell layer of all animals exposed to 500 ppm. Pronounced granule cell degeneration was found in one animal exposed to 500 ppm. The granule cell layer of animals exposed to 100 ppm appeared qualitatively normal. The alterations reported here support the few earlier reports of morphological alterations in the CNS of adult laboratory animals. Effects of **toluene** similar to those described, that is alterations in specific neuron populations and their afferent and efferent terminal fields may complement changes in neurophysiology and behavior that have been observed in prenatally and perinatally exposed rodent pups. Causal relationships, however, remain to be elucidated.
[Slomianka L et al; Toxicol 62 (2): 189-202 (1990)]**PEER REVIEWED**

The aim of the present study was to investigate the effects of **toluene** on fetal development in well nourished and malnourished rats. Long-term behavioral consequences after in utero exposure were also studied. **Toluene** (1.2 g/kg sc) was administered daily to well nourished and to malnourished (food restricted to 50% of ad libitum intake) pregnant rats, during the second (8-15 days) or the third week of pregnancy (14-20 days). Offspring were evaluated for malformation, development of the skeleton, prenatal growth of the brain and liver, postnatal growth and long lasting behavioral effects. In utero exposure to **toluene** during the third week of pregnancy resulted in low body weight at birth, which persisted in the male offspring into adulthood. Malnutrition increased fetal susceptibility to the effects of **toluene** as indicated by evaluation of the development of the skeleton. Behavioral tests performed when the pups were 30 and 90 days old showed effects of in utero malnutrition (increased ambulation and worse performance in a shuttle box), but no behavioral effects related to **toluene** exposure were detected. These data indicate that in utero exposure to **toluene** can have long lasting effects on body growth and that maternal malnutrition increases the risk for **toluene** fetotoxicity.
[Silva V AD et al; Toxicol 64 (2): 155-68 (1990)]**PEER REVIEWED**

Toluene did not induce gene mutations in Salmonella typhimiurium strain TA98, TA100, TA1535, or TA1537 with or without exogenous metabolic activation. In the mouse lymphoma assay, **toluene** gave an equivocal response with and without exogenous metabolic activation. **Toluene** did not induce sister chromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of exogenous metabolic activation.
[DHHS/NTP; Toxicology and Carcinogenesis Studies of Chlorobenzene in F344/N Rats and B6C3F1 Mice (Inihalation Studies) p.4 (1990) Technical Rpt Series No. 371 NIH Pub No. 90-2826]**PEER REVIEWED**

... **Toluene** can alter learned behavior at concentrations below anesthetic levels but, in general, above 1000 ppm.

Animal studies in mice exposed to **toluene** at concentrations of 2.5-500 ppm demonstrated decreased host defense to respiratory infections.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1092]**PEER REVIEWED**

The cardiovascular response of 25 mongrel dogs following exposure to 30,000 ppm **toluene** for 9-10 min was complex. For most of the animals, there was no change in electrocardiogram readings for the first 3-4 min of exposure. The heartbeat then became rapid for several minutes, and was followed by a period of bradycardia. Immediately before death ventricular fibrillation was noted. ... Four of the dogs were particularly sensitive, their ventricular arrhythmias were transient and accompanied by fluctuations of blood pressure. The authors suggested that **toluene** had a direct effect on the septal and ventricular muscles of the heart which permitted the development of fatal arrhythmias in sensitive dogs.
[Ikeda N et al; Forensic Sci Intern 44: 151-8 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.31 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Mice exposed for 3 hr to **toluene** at concentrations of 2.5-500 ppm exhibited increased, but not dose-related, susceptibility to respiratory infections when challenged by Streptococcus zooepidemicus.

Pulmonary bactericidal activity was decreased at concentrations of 2.5 ppm and 100-500 ppm but not at concentrations of 5-50 ppm. There was no effect on susceptibility to infection with a **toluene** exposure of 1 ppm for 3 hr, 5 days (3 hr/day) or 4 wk (3 hr/day). The bactericidal activity of the lung was decreased during the 5-day treatment but not with the 4-wk treatment. The authors hypothesized that **toluene** exerted an adverse effect on alveolar macrophage function, thereby decreasing disease resistance.
[Aranyi C et al; Toxicol Lett 25: 103-10 (1985) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.39 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Studies have demonstrated that **toluene** can produce subtle changes in the auditory system. Intermediate exposure to **toluene** produced a permanent loss of hearing in the high frequency range (approximately 16 kHz) in rats exposed to 1200 ppm for 5-9 wk or 1000 ppm for 2 wk.
[Pryor GT, Rebert CS; Neurotoxicology 13: 225-34 (1992) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.44 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

In 3-day-old rats, daily 15 min exposures to **toluene** resulted in a dose-related increase in righting-reflex latency time. At each dose the righting-reflex latency decreased over the first 4 wk of exposure indicating that the animals had developed at least partial tolerance to the **toluene**. During the second 4-wk period, latencies increased again at the higher doses but were never as great as they were for the initial **toluene** exposure. The results for the second 4-wk period showed that there were limitations to the adaptive response at the higher **toluene** doses and that there were cumulative effects of exposure at these doses. Tolerance was probably the result of induction of **toluene** metabolizing enzymes.
[Lorenzana-Jimenez M, Salas M; Neurotoxicol Teratol 12: 353-7 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Concentrations of 480 ppm and above decreased the ability of trained rats to perform a sequence of lever press actions associated with a reward (milk). During training, the rats were divided into two groups. The reward presentation for one group was not accompanied by any noticeable external events. For the second group, the reward presentation was accompanied by light and sound stimuli. The effects of **toluene** on performance were less severe with the rats trained using the light and sound reinforcement. This suggests that behavior associated with external signals is less subject to disruption by **toluene** than behavior that is not accompanied by external reinforcement.
[Wood RW et al; Toxicol Appl Pharmacol 68: 462-72 (1983) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Age ... influences neurological response after exposure to **toluene**. Young rats (50 days old) were affected by **toluene** to a lesser extent than older rats (120 days old) based on several measurements of escape latency 30 days after exposure to 30,000-40,000 ppm for 15 min/day.
[Castilla-Serna L et al; Arch Invest Med 22: 295-301 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances &

Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Toluene exposure ... changes sleep patterns in animals. Both single episodes of **toluene** exposure (about 1000 ppm) and subchronic 8 hr/day exposures for 3 wk (about 600 ppm), changed patterns of sleep and wakefulness in rats. After the single exposures, there was a decrease in wakefulness and an increase in slow-wave sleep; a prolonged sleep latency was apparent for the 2 days following exposure. Latency was defined as the time interval between the end of the exposure period and the beginning of a particular phase of the sleep cycle. Following the 3 wk exposures, there was an increase in wakefulness during the dark period on the 2 days after exposure and a decrease in slow wave sleep on the first day.
[Arito H et al; Arch Toxicol 62: 76-80 (1988) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Brain levels of norepinephrine, dopamine, serotonin, vanillylmandelic acid, homovanillic acid, and 5-hydroxyindolacetic acid were altered in six areas of the brain in male CD-1 mice administered **toluene** (5-105 mg/kg/day) in their drinking water for a 28-day period. Significant increases of norepinephrine, dopamine, and serotonin were present in the hypothalamus at all dose levels. The maximum increase occurred with the 22 mg/kg/day dose and there were lesser increases for both the 5 and 105 mg/kg/day doses, giving biphasic response. Roughly similar fluctuations were seen in the concentrations of vanillylmandelic acid and homovanillic acid, which are metabolites of dopamine and norepinephrine and 5-hydroxyindolacetic acid, a serotonin metabolite. In corpus striatum, the levels of dopamine and serotonin were significantly increased at the two highest doses. The level of vanillylmandelic acid was also increased significantly at the same doses. In the medulla oblongata, the concentrations of norepinephrine, vanillylmandelic acid, and 5-hydroxyindolacetic acid were significantly increased at the 22 mg/kg/day dose, but not at the other doses, while the levels of serotonin were significantly increased at the 22 and 105 mg/kg/day doses. Norepinephrine concentrations were elevated in the midbrain. ...
[U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.61 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

To identify the frequency range most sensitive to **toluene**-induced auditory damage, the auditory function of adult Long-Evans rats exposed to 1750 ppm of **toluene** (6 h/day, 5 days/week, 4 weeks), was tested by recording auditory-evoked potentials directly from the round window of the cochlea. The present electrocochleographic findings do not support a specific mid- to high-frequency loss of auditory sensitivity. On the contrary, the electrophysiologic data, obtained for audiometric frequencies ranging from 2 to 32 kHz, showed a hearing deficit not only in the mid-frequency region (12-16 kHz), but also in the mid-low-frequency region (3-4 kHz). Actually, the effect of **toluene** was independent of the frequency in our experimental conditions. Histological analysis was consistent with electrophysiologic data because a broad loss of outer hair cells occurred in both mid- and mid-apical coil of the organ of Corti.
[Lataye R et al; Neurotoxicol Teratol 21 (3): 267-76 (1999)]**PEER REVIEWED**

National Toxicology Program Studies:

Long-term studies were conducted by exposing groups of 60 rats /F344/N/ of each sex to 0, 600, or 1,200 ppm **toluene** by inhalation, 6.5 hours per day, 5 days per week. Groups of 60 /B6C3F1/ mice of each sex were exposed at 0, 120, 600, or 1,200 ppm on the same schedule. ... Animals were exposed to **toluene** for 103 weeks. Nephropathy was seen in almost all rats, and the severity was somewhat increased in exposed rats. A rare renal tubular cell carcinoma in a female rat and an equally uncommon sarcoma of the kidney in another female rat were seen in the 1,200 ppm exposure group. Erosion of the olfactory epithelium and degeneration of the respiratory epithelium were increased in exposed rats. Inflammation of the nasal mucosa and metaplasia of the olfactory epithelium were increased in exposed female rats. A rare squamous cell carcinoma of the nasal mucosa was seen in one female rat at 1,200 ppm. A squamous cell papilloma of the forestomach was observed in one female rat at 1,200 ppm, and a squamous cell carcinoma was observed in a second female rat at 1,200 ppm. No chemically related neoplasms were found in male rats, and the one nasal, two kidney, and two forestomach neoplasms observed in female rats were considered not to be associated with inhalation exposure to **toluene**. For mice, no biological important increases were observed for any nonneoplastic or neoplastic lesions.

TSCA Test Submissions:

Neurotoxicity was determined in groups of rats (4 male and 4 female, strain not reported) exposed by inhalation to 0,100, or 1500 ppm **toluene** (purity not reported) 6 hrs/day, 5 days/week for periods up to 27 weeks. Histological sections of selected areas of the brainstem were made for the upper medulla oblongata (including dorsal and ventral cochlear and vestibular nuclei), lower metencephalon (including superior olivary nuclei, trapezoid body and ventral cochlear nuclei), upper metencephalon (including the lateral lemniscus, superior olivary nuclei, cochlear and vestibular nuclei, and inferior colliculus) and the mesencephalon-diencephalon junction (including the medial geniculate). The investigators reported that the "vast majority" of sections from animals exposed to **toluene** were indistinguishable from controls. Shrunken and darkly stained neurons were observed in the corpus trapezoid of one animal exposed to 100 ppm and another exposed to 1500 ppm **toluene**; these were present in only one section and not in sufficient quantity to be considered a positive response by the investigators. Statistical analysis of the results was not reported.
[American Petroleum Inst.; Effects of Toluene Exposure on Auditory Pathways, Final Report. (1979), EPA Document No. 40-8450019, Fiche No. OTS0507495] **UNREVIEWED**

Chronic toxicity was evaluated in male and female Sprague Dawley rats (15/sex/group) exposed to **toluene** via inhalation at 0, 100 and 1500 ppm for 6 hrs/day, 5 days/week for 26 weeks. There were significant increases in the hematocrit and hemoglobin levels in females at 1500 ppm in the 13th week. There were significant differences in females at week 26 in the following: decreased mean blood clotting time and increased mean serum glutamic pyruvic transaminase at 100 ppm level, and decreases in glucose levels at 1500 ppm. There were no significant differences between treated and control animals in urinalysis.
[American Petroleum Institute; 26 Week Inhalation Toxicity Study in the Rat (1980), EPA Document No. FYI-AX-1081-0136, Fiche No. 0136-0] **UNREVIEWED**

Teratogenicity was evaluated in mated female CRL:COBS CD (SD) BR rats (27/group) exposed to **toluene** by inhalation at nominal concentrations of 0, 100 or 400 ppm on gestation days (GD) 6-15 for 6 hrs/day. The adult female rats were sacrificed on GD 20 and examined. There were no significant differences observed between treated and control animals in the following: maternal mortality, body weights, food consumption, examination of tissues and organs at necropsy (except an insignificant number of observations of mottled lungs in 4 high-dose group rats), pregnancy rate, live litters, implantation sites, resorptions, litters with resorptions, dead pups, litters with dead pups, live pups/implantation site, mean live litter size, average pup weights, fetal sex ratio, examination of soft tissues of the head, thoracic and visceral organs, and skeletal abnormalities.

The ability of **toluene** to induce specific locus mutations at the TK locus in cultured L5178Y mouse lymphoma cells (Mouse Lymphoma Mutagenesis Assay) was evaluated in the presence and absence of

mouse liver S9 metabolic activation. Based on preliminary toxicity tests, both nonactivated and S9-activated cultures were treated with 0.30, 0.20, 0.15, 0.10, or 0.050 ul/ml produced a range of 7 - 78% total growth for nonactivated cultures and from 60 - 138% total growth for S9-activated cultures. None of the nonactivated or activated cultures produced mutant frequencies significantly greater than the solvent (DMSO) controls.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain D4, both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, **toluene**, diluted with acetone, was tested for mutagenicity at concentrations up to 5.0 ul/plate using both the plate and suspension assay methods. **Toluene** did not cause a positive response in any of the bacterial or yeast tester strains, either with or without metabolic activation.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in a dominant lethal assay using three groups of male CD-1 mice (12/group) receiving whole body exposures to nominal concentrations of test material at 0, 100 or 400 ppm for 6 hrs/day, 5 days/week for 8 weeks. Following exposure, each male was mated with two untreated females/week for two consecutive weeks. Females were sacrificed 14 days after the midweek of mating. There was no effect of treatment for all dosed male mice as indicated by mortality, body weight and in-life physical observations. There were no significant differences between treated and control females with respect to fertility indices, average number of implants/pregnant female, average number of dead implants/pregnant female, and proportions of female with one or more dead implants.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene, Mouse Dominant Lethal Assay, Final Report. (1981), EPA Document No. FYI-AX-1081-0136, Fiche No. OTS0000136-0] **UNREVIEWED**

The ability of **toluene** to cause chromosome aberrations in the bone marrow cells of male Charles River rats exposed by intraperitoneal injection at dose levels of 0, 0.025, 0.082 or 0.247 cc/kg (in DMSO solvent, 0.65 cc/rat/day), either once in an acute study (15 rats/group) or once each day for 5 days in a subchronic study (5 rats/group) was evaluated. Five rats/group in the acute study were sacrificed 6, 24 or 48 hrs following dosing and the rats in the subchronic study were sacrificed 6 hrs after administration of the last dose. 50 cells/animal were scored for chromosome aberrations. None of the cells from any of the treated animals exhibited a significant increase in the frequency of chromosome aberrations.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The percutaneous absorption of **toluene** was evaluated in six human volunteers. A glass ring having an area of 13cm(2) was placed against the palm and 2ml of 14C-**toluene** was applied. After one minute the ring was removed and adherent liquid allowed to evaporate. All urine was collected and analyzed for radioactive content until background levels of activity were approached. **Toluene** absorption was very low, averaging .022ul/cm(2) for the six human subjects.
[Thomas J. Franz M.D.; Absorption of Petroleum Products Across the Skin of Man and Monkey, Draft Report, (no date), EPA Document No. FYI-AX-0187-0185, Fiche No. OTS0000185-4] **UNREVIEWED**

... Groups of rats were trained on the conditioned avoidance response task during the last week of a 5 week exposure to 1400 or 1200 ppm **toluene** (14 hr/day, 7 days/week) or during the first or third weeks after the exposure ended. None of the three groups ... were able to acquire the auditory condition avoidance response ... . Subsequent tests ... revealed that hearing with these rats was unimpaired at 4 KHz, slightly impaired at 8 KHz, and markedly impaired at 12 KHz and above.
[Pryor GT et al; Neurobehav Toxicol Terat 5 (1): 53-7 (1983)]**PEER REVIEWED**

Pregnant CD-1 mice were housed singly in multicompartment cages in inhalation chambers and exposed to **toluene** at a concentration of 0, 750, or 1500 mg/cu m (0, 200, or 400 ppm) for 7 hrs/day from day 7 through day 16 of gestation. The mice were killed on day 17 of gestation and the fetuses were removed and examined. Maternal weight gain was not affected by **toluene** exposure but the liver to body weight ratio was significantly reduced. The treated dams showed no significant differences in the average number of implantation sites, number of live fetuses, fetal mortality, or fetal body weight at either **toluene** concentration compared to control values. The incidence of enlarged renal pelvis was significantly greater in fetuses exposed to 200 ppm than in the fetuses exposed to 400 ppm or in the controls. A shift in rib profile (number of fetuses with 13 ribs) was observed in the higher **toluene** concentration group, and this shift was significantly different from the rib profile of controls. There was an increase in the total activity of lactic dehydrogenase activity in the brain of the dams from the 400 ppm group. The total activity of lactic dehydrogenase in the **toluene** exposed pups did not differ significantly from the controls for liver, heart, lung, or kidney, but the brain lactic dehydrogenase activity of the treated group was slightly greater than the control value.
[Courtney KD et al; Fundam Appl Toxicol 6: 145-54 (1986)]**PEER REVIEWED**

Behavioral toxicity of **toluene** was assessed in mice confined in a 20 liter hermetically sealed chamber for several hours. **Toluene** was introduced through a port and volatilized by a hot plate. Samples of chamber air for analysis were taken through another port. A smaller mesh cage held the mouse within the larger chamber. Schedule-controlled responding was developed by arranging that a response, breaking a beam of light, was followed by mild (under an F1 60 sec) schedule. Responding was much more rapid in the presence of stimuli correlated with the F1 schedule than when the schedule was not operating. Standard sessions consisted of alternating series of 8 consecutive F1 60 sec and inter-series 30 min time-outs. Concentration-effect curves were determined by exposing a mouse to incremental additions of **toluene** at 30 min intervals. **Toluene** increased the rate of responding in most mice at levels of about 700 ppm. Higher concentrations progressively reduced responding. The ED50 (the concentration reducing responding by 50%) averaged 1657 ppm in 10 mice. It is estimated that there is a 1/1000 chance /ED001/ of the responding of a mouse being reduced by as much as 10% by a concentration of **toluene** of 69 ppm.
[Glowa JR et al; J Environ Pathol Toxicol Oncol 6 (5-6): 153-68 (1986)]**PEER REVIEWED**

Sixteen rats were chronically implanted with bipolar electrodes in the hipocampal regions containing cells generating electric theta-activity. The animals were divided into 4 groups of which 2 were exposed to 500 ppm of **toluene** in inhalation chambers, for 8 or 16 hours per day for 5 days per week in 12 weeks respectively, and 2 served as controls. The hippocampal electric activity was recorded 48 hours after each weekly exposure. Frequencies of theta-activity in the exposed groups were found to differ from their respective control group by variance analysis. Each point on the frequency versus time plot were further analysed by Student's t-test. Compared to the non-exposed group the eight hours daily exposed

showed an initial period of increased frequency of the regular theta-waves together with an increased incidence of theta-activity after 1-2 weeks of exposure. In the sixteen hours daily exposed rats two weeks of **toluene** inhalation produced a significant reduction in the theta-wave frequency. This change was also reached after either weeks of exposure in the eight hours daily exposed group. At this moment the theta-activity was frequency disrupted by short amplitude irregular waves, a phenomen which increased gradually throughout the rest of the exposure period. The average blood concentration of **toluene** was 16.7 ug/ml and 17.7 ug/ml and not significantly different for the eight and sixteen hours exposed groups respectively.
[Naalsund LU; Acta Pharmacol Toxicol 59 (4): 325-31 (1988)]**PEER REVIEWED**

The effects of **toluene** vapors on brain lipid changes were investigated in male Sprague-Dawley rats. The animals (8/group) were continuously exposed to 320 ppm **toluene** for 30 days. Controls were exposed to air. Exposed animals showed decreased body weight ($p< 0.01$), decreased brain weight ($p< 0.01$), and a decrease in the weight of the cerebral cortex ($p< 0.05$) when compared to controls. In the cerebral cortex of exposed rats, total phospholipids was reduced ($p< 0.001$), there was an increase in phosphatidic acid ($p< 0.05$) and a decrease in a minor fatty acid of ethanolamine phosphoglyceride ($p< 0.05$). No changes in lipids were found in the brain stem.
[Kyrklund T et al; Toxicology 45: 123-33 (1987)]**PEER REVIEWED**

With the intention of investigating possible morphological alterations effected by **toluene** in the developing CNS, rat pups were exposed to 100 ppm and 500 ppm of atmospheric **toluene** from postnatal day 1 until sacrifice at postnatal day 28, when the hippocampal region (area dentata, Ammon's horn, subiculum) was examined by light microscope and alterations in the volumes of the layers of the subdivisions were determined. The layers of Ammon's horn and the subiculum were not affected qualitatively or quantitatively by the 500 ppm exposure. Within the area dentata, the volume of the granule cell layer was 6% smaller in animals exposed to 100 ppm and 13% smaller in animals exposed to 500 ppm than they were in controls. The volumes of the hilus, which is a terminal field of granule cell axons, and the commissural-association zone of the dentate molecular layer, which is the terminal field of the hilar projection to the granule cells, were smaller (12% and 19%) in animals exposed to 500 ppm than they were in controls. Argyrophilic cells were found in the granule cell layer of all animals exposed to 500 ppm. Pronounced granule cell degeneration was found in one animal exposed to 500 ppm. The granule cell layer of animals exposed to 100 ppm appeared qualitatively normal. The alterations reported here support the few earlier reports of morphological alterations in the CNS of adult laboratory animals. Effects of **toluene** similar to those described, that is alterations in specific neuron populations and their afferent and efferent terminal fields may complement changes in neurophysiology and behavior that have been observed in prenatally and perinatally exposed rodent pups. Causal relationships, however, remain to be elucidated.
[Slomianka L et al; Toxicol 62 (2): 189-202 (1990)]**PEER REVIEWED**

The aim of the present study was to investigate the effects of **toluene** on fetal development in well nourished and malnourished rats. Long-term behavioral consequences after in utero exposure were also studied. **Toluene** (1.2 g/kg sc) was administered daily to well nourished and to malnourished (food restricted to 50% of ad libitum intake) pregnant rats, during the second (8-15 days) or the third week of pregnancy (14-20 days). Offspring were evaluated for malformation, development of the skeleton, prenatal growth of the brain and liver, postnatal growth and long lasting behavioral effects. In utero exposure to **toluene** during the third week of pregnancy resulted in low body weight at birth, which

persisted in the male offspring into adulthood. Malnutrition increased fetal susceptibility to the effects of **toluene** as indicated by evaluation of the development of the skeleton. Behavioral tests performed when the pups were 30 and 90 days old showed effects of in utero malnutrition (increased ambulation and worse performance in a shuttle box), but no behavioral effects related to **toluene** exposure were detected. These data indicate that in utero exposure to **toluene** can have long lasting effects on body growth and that maternal malnutrition increases the risk for **toluene** fetotoxicity.
[Silva V AD et al; Toxicol 64 (2): 155-68 (1990)]**PEER REVIEWED**

Toluene did not induce gene mutations in Salmonella typhimiurium strain TA98, TA100, TA1535, or TA1537 with or without exogenous metabolic activation. In the mouse lymphoma assay, **toluene** gave an equivocal response with and without exogenous metabolic activation. **Toluene** did not induce sister chromatid exchanges or chromosomal aberrations in Chinese hamster ovary cells in the presence or absence of exogenous metabolic activation.
[DHHS/NTP; Toxicology and Carcinogenesis Studies of Chlorobenzene in F344/N Rats and B6C3F1 Mice (Inihalation Studies) p.4 (1990) Technical Rpt Series No. 371 NIH Pub No. 90-2826]**PEER REVIEWED**

... **Toluene** can alter learned behavior at concentrations below anesthetic levels but, in general, above 1000 ppm.

99 (1989)]**PEER REVIEWED**

Animal studies in mice exposed to **toluene** at concentrations of 2.5-500 ppm demonstrated decreased host defense to respiratory infections.
[Sullivan, J.B. Jr., G.R. Krieger (eds.). Hazardous Materials Toxicology-Clinical Principles of Environmental Health. Baltimore, MD: Williams and Wilkins, 1992. 1092]**PEER REVIEWED**

The cardiovascular response of 25 mongrel dogs following exposure to 30,000 ppm **toluene** for 9-10 min was complex. For most of the animals, there was no change in electrocardiogram readings for the first 3-4 min of exposure. The heartbeat then became rapid for several minutes, and was followed by a period of bradycardia. Immediately before death ventricular fibrillation was noted. ... Four of the dogs were particularly sensitive, their ventricular arrhythmias were transient and accompanied by fluctuations of blood pressure. The authors suggested that **toluene** had a direct effect on the septal and ventricular muscles of the heart which permitted the development of fatal arrhythmias in sensitive dogs.
[Ikeda N et al; Forensic Sci Intern 44: 151-8 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.31 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Mice exposed for 3 hr to **toluene** at concentrations of 2.5-500 ppm exhibited increased, but not dose-related, susceptibility to respiratory infections when challenged by Streptococcus zooepidemicus. Pulmonary bactericidal activity was decreased at concentrations of 2.5 ppm and 100-500 ppm but not at concentrations of 5-50 ppm. There was no effect on susceptibility to infection with a **toluene** exposure of 1 ppm for 3 hr, 5 days (3 hr/day) or 4 wk (3 hr/day). The bactericidal activity of the lung was decreased during the 5-day treatment but not with the 4-wk treatment. The authors hypothesized that **toluene** exerted an adverse effect on alveolar macrophage function, thereby decreasing disease resistance.
[Aranyi C et al; Toxicol Lett 25: 103-10 (1985) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.39 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Studies have demonstrated that **toluene** can produce subtle changes in the auditory system. Intermediate exposure to **toluene** produced a permanent loss of hearing in the high frequency range (approximately 16 kHz) in rats exposed to 1200 ppm for 5-9 wk or 1000 ppm for 2 wk.
[Pryor GT, Rebert CS; Neurotoxicology 13: 225-34 (1992) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.44 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

In 3-day-old rats, daily 15 min exposures to **toluene** resulted in a dose-related increase in righting-reflex latency time. At each dose the righting-reflex latency decreased over the first 4 wk of exposure indicating that the animals had developed at least partial tolerance to the **toluene**. During the second 4-wk period, latencies increased again at the higher doses but were never as great as they were for the initial **toluene** exposure. The results for the second 4-wk period showed that there were limitations to the adaptive response at the higher **toluene** doses and that there were cumulative effects of exposure at these doses. Tolerance was probably the result of induction of **toluene** metabolizing enzymes.

[Lorenzana-Jimenez M, Salas M; Neurotoxicol Teratol 12: 353-7 (1990) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Concentrations of 480 ppm and above decreased the ability of trained rats to perform a sequence of lever press actions associated with a reward (milk). During training, the rats were divided into two groups. The reward presentation for one group was not accompanied by any noticeable external events. For the second group, the reward presentation was accompanied by light and sound stimuli. The effects of **toluene** on performance were less severe with the rats trained using the light and sound reinforcement. This suggests that behavior associated with external signals is less subject to disruption by **toluene** than behavior that is not accompanied by external reinforcement.
[Wood RW et al; Toxicol Appl Pharmacol 68: 462-72 (1983) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.45 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Age ... influences neurological response after exposure to **toluene**. Young rats (50 days old) were affected by **toluene** to a lesser extent than older rats (120 days old) based on several measurements of escape latency 30 days after exposure to 30,000-40,000 ppm for 15 min/day.
[Castilla-Serna L et al; Arch Invest Med 22: 295-301 (1991) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Toluene exposure ... changes sleep patterns in animals. Both single episodes of **toluene** exposure (about 1000 ppm) and subchronic 8 hr/day exposures for 3 wk (about 600 ppm), changed patterns of sleep and wakefulness in rats. After the single exposures, there was a decrease in wakefulness and an increase in slow-wave sleep; a prolonged sleep latency was apparent for the 2 days following exposure. Latency was defined as the time interval between the end of the exposure period and the beginning of a particular phase of the sleep cycle. Following the 3 wk exposures, there was an increase in wakefulness during the dark period on the 2 days after exposure and a decrease in slow wave sleep on the first day.
[Arito H et al; Arch Toxicol 62: 76-80 (1988) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.46 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Brain levels of norepinephrine, dopamine, serotonin, vanillylmandelic acid, homovanillic acid, and 5-hydroxyindolacetic acid were altered in six areas of the brain in male CD-1 mice administered **toluene** (5-105 mg/kg/day) in their drinking water for a 28-day period. Significant increases of norepinephrine, dopamine, and serotonin were present in the hypothalamus at all dose levels. The maximum increase occurred with the 22 mg/kg/day dose and there were lesser increases for both the 5 and 105 mg/kg/day doses, giving biphasic response. Roughly similar fluctuations were seen in the concentrations of vanillylmandelic acid and homovanillic acid, which are metabolites of dopamine and norepinephrine and 5-hydroxyindolacetic acid, a serotonin metabolite. In corpus striatum, the levels of dopamine and serotonin were significantly increased at the two highest doses. The level of vanillylmandelic acid was also increased significantly at the same doses. In the medulla oblongata, the concentrations of

norepinephrine, vanillylmandelic acid, and 5-hydroxyindolacetic acid were significantly increased at the 22 mg/kg/day dose, but not at the other doses, while the levels of serotonin were significantly increased at the 22 and 105 mg/kg/day doses. Norepinephrine concentrations were elevated in the midbrain. ...
[U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.61 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

To identify the frequency range most sensitive to **toluene**-induced auditory damage, the auditory function of adult Long-Evans rats exposed to 1750 ppm of **toluene** (6 h/day, 5 days/week, 4 weeks), was tested by recording auditory-evoked potentials directly from the round window of the cochlea. The present electrocochleographic findings do not support a specific mid- to high-frequency loss of auditory sensitivity. On the contrary, the electrophysiologic data, obtained for audiometric frequencies ranging from 2 to 32 kHz, showed a hearing deficit not only in the mid-frequency region (12-16 kHz), but also in the mid-low-frequency region (3-4 kHz). Actually, the effect of **toluene** was independent of the frequency in our experimental conditions. Histological analysis was consistent with electrophysiologic data because a broad loss of outer hair cells occurred in both mid- and mid-apical coil of the organ of Corti.

National Toxicology Program Studies:

Long-term studies were conducted by exposing groups of 60 rats /F344/N/ of each sex to 0, 600, or 1,200 ppm **toluene** by inhalation, 6.5 hours per day, 5 days per week. Groups of 60 /B6C3F1/ mice of each sex were exposed at 0, 120, 600, or 1,200 ppm on the same schedule. ... Animals were exposed to **toluene** for 103 weeks. Nephropathy was seen in almost all rats, and the severity was somewhat increased in exposed rats. A rare renal tubular cell carcinoma in a female rat and an equally uncommon sarcoma of the kidney in another female rat were seen in the 1,200 ppm exposure group. Erosion of the olfactory epithelium and degeneration of the respiratory epithelium were increased in exposed rats. Inflammation of the nasal mucosa and metaplasia of the olfactory epithelium were increased in exposed female rats. A rare squamous cell carcinoma of the nasal mucosa was seen in one female rat at 1,200 ppm. A squamous cell papilloma of the forestomach was observed in one female rat at 1,200 ppm, and a squamous cell carcinoma was observed in a second female rat at 1,200 ppm. No chemically related neoplasms were found in male rats, and the one nasal, two kidney, and two forestomach neoplasms observed in female rats were considered not to be associated with inhalation exposure to **toluene**. For mice, no biological important increases were observed for any nonneoplastic or neoplastic lesions.

TSCA Test Submissions:

Neurotoxicity was determined in groups of rats (4 male and 4 female, strain not reported) exposed by inhalation to 0,100, or 1500 ppm **toluene** (purity not reported) 6 hrs/day, 5 days/week for periods up to 27 weeks. Histological sections of selected areas of the brainstem were made for the upper medulla oblongata (including dorsal and ventral cochlear and vestibular nuclei), lower metencephalon (including superior olivary nuclei, trapezoid body and ventral cochlear nuclei), upper metencephalon (including the lateral lemniscus, superior olivary nuclei, cochlear and vestibular nuclei, and inferior colliculus) and the mesencephalon-diencephalon junction (including the medial geniculate). The investigators reported that the "vast majority" of sections from animals exposed to **toluene** were indistinguishable from controls. Shrunken and darkly stained neurons were observed in the corpus trapezoid of one animal exposed to 100 ppm and another exposed to 1500 ppm **toluene**; these were present in only one section and not in sufficient quantity to be considered a positive response by the investigators. Statistical analysis of the results was not reported.
[American Petroleum Inst.; Effects of Toluene Exposure on Auditory Pathways, Final Report. (1979), EPA Document No. 40-8450019, Fiche No. OTS0507495] **UNREVIEWED**

Chronic toxicity was evaluated in male and female Sprague Dawley rats (15/sex/group) exposed to **toluene** via inhalation at 0, 100 and 1500 ppm for 6 hrs/day, 5 days/week for 26 weeks. There were significant increases in the hematocrit and hemoglobin levels in females at 1500 ppm in the 13th week. There were significant differences in females at week 26 in the following: decreased mean blood clotting time and increased mean serum glutamic pyruvic transaminase at 100 ppm level, and decreases in glucose levels at 1500 ppm. There were no significant differences between treated and control animals in urinalysis.
[American Petroleum Institute; 26 Week Inhalation Toxicity Study in the Rat (1980), EPA Document No. FYI-AX-1081-0136, Fiche No. 0136-0] **UNREVIEWED**

Teratogenicity was evaluated in mated female CRL:COBS CD (SD) BR rats (27/group) exposed to **toluene** by inhalation at nominal concentrations of 0, 100 or 400 ppm on gestation days (GD) 6-15 for 6 hrs/day. The adult female rats were sacrificed on GD 20 and examined. There were no significant differences observed between treated and control animals in the following: maternal mortality, body weights, food consumption, examination of tissues and organs at necropsy (except an insignificant number of observations of mottled lungs in 4 high-dose group rats), pregnancy rate, live litters, implantation sites, resorptions, litters with resorptions, dead pups, litters with dead pups, live pups/implantation site, mean live litter size, average pup weights, fetal sex ratio, examination of soft tissues of the head, thoracic and visceral organs, and skeletal abnormalities.

The ability of **toluene** to induce specific locus mutations at the TK locus in cultured L5178Y mouse

lymphoma cells (Mouse Lymphoma Mutagenesis Assay) was evaluated in the presence and absence of mouse liver S9 metabolic activation. Based on preliminary toxicity tests, both nonactivated and S9-activated cultures were treated with 0.30, 0.20, 0.15, 0.10, or 0.050 ul/ml produced a range of 7 - 78% total growth for nonactivated cultures and from 60 - 138% total growth for S9-activated cultures. None of the nonactivated or activated cultures produced mutant frequencies significantly greater than the solvent (DMSO) controls.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538, and the yeast Saccharomyces cerevisiae tester strain D4, both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary bacterial toxicity determinations, **toluene**, diluted with acetone, was tested for mutagenicity at concentrations up to 5.0 ul/plate using both the plate and suspension assay methods. **Toluene** did not cause a positive response in any of the bacterial or yeast tester strains, either with or without metabolic activation.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene. (1978), EPA Document No. 878210352, Fiche No. OTS0205936] **UNREVIEWED**

The mutagenicity of **toluene** was evaluated in a dominant lethal assay using three groups of male CD-1 mice (12/group) receiving whole body exposures to nominal concentrations of test material at 0, 100 or 400 ppm for 6 hrs/day, 5 days/week for 8 weeks. Following exposure, each male was mated with two untreated females/week for two consecutive weeks. Females were sacrificed 14 days after the midweek of mating. There was no effect of treatment for all dosed male mice as indicated by mortality, body weight and in-life physical observations. There were no significant differences between treated and control females with respect to fertility indices, average number of implants/pregnant female, average number of dead implants/pregnant female, and proportions of female with one or more dead implants.
[Litton Bionetics, Inc.; Mutagenicity Evaluation of Toluene, Mouse Dominant Lethal Assay, Final Report. (1981), EPA Document No. FYI-AX-1081-0136, Fiche No. OTS0000136-0] **UNREVIEWED**

The ability of **toluene** to cause chromosome aberrations in the bone marrow cells of male Charles River rats exposed by intraperitoneal injection at dose levels of 0, 0.025, 0.082 or 0.247 cc/kg (in DMSO solvent, 0.65 cc/rat/day), either once in an acute study (15 rats/group) or once each day for 5 days in a subchronic study (5 rats/group) was evaluated. Five rats/group in the acute study were sacrificed 6, 24 or 48 hrs following dosing and the rats in the subchronic study were sacrificed 6 hrs after administration of the last dose. 50 cells/animal were scored for chromosome aberrations. None of the cells from any of the treated animals exhibited a significant increase in the frequency of chromosome aberrations.

Metabolism/Pharmacokinetics:

Metabolism/Metabolites:

Toluene is extensively metabolized via oxidation to benzyl alcohol then to benzaldehyde by alcohol dehydrogenase. Further oxidation then forms benzoic acid. Conjugation with glycine produces the major metabolite, hippuric acid, which is excreted in the urine. Benzyl glucuronide is formed in smaller amounts by conjugation with glucuronic acid.

In mammalian species, acidic metabolites are conjugated with glycine to form hippuric acid and phenylacetic acid. In humans, the phenylacetic acid metabolite is also conjugated with glutamine to form phenacetylglutamine.
[James MO et al; Proc R Soc Lond Ser B 182: 25-35 (1972) as cited in NRC; Alkyl Benzenes p.219 (1981)]**PEER REVIEWED**

The association between occupational **toluene** exposure and blood and adipose tissue **toluene** concentrations was examined. Breathing zone samples were monitored for **toluene** in two Swedish rotogravure printing facilities. Sc adipose tissues were taken from 37 workers after work on Thursday or Friday and analyzed for **toluene**. Venous blood samples were taken from 11 workers after work on Friday and at various times over the following weekend and assayed for **toluene**. Blood and adipose tissue samples were obtained from 11 other workers immediately after work and after 63 and 135 hours nonexposure and analyzed for **toluene**. Blood samples were also taken from 21 unexposed workers and analyzed for **toluene**. Attempts were made to fit the blood **toluene** data to various pharmacokinetics models. Airborne **toluene** concentrations in the printing factories ranged from 8 to 416 mg/cu m, median 75 mg/cu m. Blood **toluene** concentrations in the unexposed workers were below the detection limit, 0.01 umole/l. Blood samples obtained immediately after work contained 0.22 to 21.4 umole/l **toluene**. Elimination of **toluene** from the blood could be described by a three compartment model having median halftimes of 9 minutes, 2 hours, and 79 hours. **Toluene** was eliminated from adipose tissue with a median halftime of 79 hours. Adipose tissue concentrations were significantly associated with the workers'

exposure to airborne **toluene** during the previous week. Adipose tissue **toluene** concentrations were significantly correlated with blood **toluene** concentrations after 70 hours exposure. It was concluded that the prolonged presence of **toluene** in the blood means that there is an endogenous exposure from adipose tissue depots that continues long after occupational exposure has ended.
[Nise G et al; Br J Ind Med 46 (6): 407-11 (1989)]**PEER REVIEWED**

Evidence has suggested that there is an ethnic related difference in organic solvent metabolism in humans; analyses were thus made to obtain evidence of strain differences in animals to assist in consolidating the observation in workers. Female Donryu, Fischer, Sprague-Dawley, and Wistar rats were exposed to **toluene** at dose levels of 5, 45, 500, 2500, and 3500 ppm for 8 hours in a dynamic flow type exposure system. Urine samples were collected for 24 hours from the start of exposure. While the variation in free p-cresol excretion was wide among the rats of the same strain exposed to **toluene** at the same concentration, it was also noted that the four strains tested could be classified into two groups depending on the free p-cresol levels at **toluene** concentrations up to 500 ppm. No significant differences were noted between Sprague-Dawley and Wistar strains nor between Donryu and Fischer strains at the 45 and 500 ppm levels. However, there were significant differences between these two groups. At higher concentrations of 2500 and 3500 ppm, the increase in the free p-cresol levels was remarkable only in Donryu rats, reaching the levels of Sprague-Dawley and Wistar rats, while the level in Fischer rats remained unchanged.
[Inoue O et al; Bull Environ Contam Toxicol 43 (1): 74-9 (1989)]**PEER REVIEWED**

The mutual metabolic suppression between benzene and **toluene** was studied. The subjects, 190 male Chinese workers employed in shoe manufacturing, printing, audio equipment manufacture, and automobile industries, were divided into four groups based on occupational exposure: 65 were exposed to benzene, 35 to **toluene**, 55 to both compounds, and 35 served as comparisons. The arithmetic mean exposure level of benzene was 31.9 and of **toluene** 44.7 ppm. The mixture contained benzene at 17.9 +/29.3 and **toluene** at 20.5 +/25.8 ppm. The exposure levels were measured using individuals diffusive samplers. The geometric mean levels of the metabolites, phenol, catechol, hydroquinone, hippuric acid, and o-cresol, in unexposed workers were 6.9, 9.4, 4.8, 72.5, and 0.066 mg per liter, respectively. Values corrected for creatinine and specific gravity were different from the values cited above. Multiple correlation coefficients for benzene exposure versus its three metabolites were for phenol, 0.740; for catechol, 0.629; and for hydroquinone, 0.726. Multiple correlation coefficients for **toluene** and its two metabolites were 0.649 for hippuric acid and 0.583 for o-cresol. The slopes of regression lines for the exposure to benzene in the presence of **toluene** were less than half of those obtained when the workers were exposed to benzene alone; however, the regression lines for benzene in mixture versus catechol were about 80% or higher than the lines observed with benzene as the sole pollutant. The regression lines for **toluene** in the mixture and excretion level of hippuric acid and o-cresol showed reduced metabolic conversion compared to when exposure was limited to **toluene** alone. It was concluded that simultaneous exposure to benzene and **toluene** results in mutual suppression of metabolism yielding the urinary metabolites phenol, hydroquinone, hippuric acid, and o-cresol.

[Bergman K; CRC Crit Review Toxicol 12 (1): 59-118 (1983)]**PEER REVIEWED**

The urinary excretion of hippuric acid and o-cresol in humans was measured after a 7 hr exposure to

toluene at a constant concn of 100 ppm but with a time-weighted avg of 100 ppm. In study A, 4 men were exposed to clean air and to constant and varying concns of **toluene** in combination with rest and with 100 W exercise for 140 min exercise increased the end-exposure excretion rate of hippuric acid and o-cresol by 47 and 114%, respectively. After exposure, all excess hippuric acid was excreted within 4 hr, while o-cresol was eliminated with a half-life of approx 3 hr. Alveolar air concn of **toluene** was 21-31 ppm during constant exposure and 13-57 ppm during varying exposure, but no difference in mean alveolar **toluene** concn or in metabolite excretion was seen between the exposure schedules. In study B, 32 men and 39 women aged between 31 and 50 yr were exposed once to either clean air or ... or varying concns of **toluene**. The background excretion rate of hippuric acid was 0.97 mg/min (1.25 g/g creatinine) and rose to 3.74 mg/min (3.90 g/g creatinine) during the last 3 hr of exposure to 100 pmm **toluene**. The corresponding figures for o-cresol were 0.05 ug/min (0.08 mg/g creatinine), and 2.04 ug/min (2.05 mg/g creatinine). The individual creatinine excretion rate was considerably influenced by sex, body wt, and smoking habits, thus influencing the metabolite concn standardized in relation to creatinine. Thus, both metabolites are estimates of **toluene** exposure; o-cresol is more specific than hippuric acid, but the individual variation in excretion of both metabolites is large, and when implementing either of them as biological exposure indexes, the influence of sex, body size, age as well as consumption of tobacco and alcohol has to be considered.
[Baelum J et al; Int Arch Occup Environ Health 59 (3): 281-94 (1987)]**PEER REVIEWED**

The distribution of radioactivity in pregnant mice was registered at different time intervals (0-24 hr) after a 10 min period of inhalation of **toluene**. ... Autoradiographic and liq scintillation methods were used to make possible the distinction between volatile, water sol, and firmly tissue bound radioactivity. **Toluene** reached high concns immediately after inhalation in lipid rich tissues (brain and fat) and well perfused organs (liver and kidney) but were rapidly eliminated resulting in low concns at 1 hr in all maternal tissues, except fat. Metabolites reached peak levels around 30 min to 1 hr after inhalation, but were also relatively rapidly eliminated. ... One exception was the very strong accumulation of water sol metabolites at 4 and 24 hr in the nasal mucosa and olfactory bulb after inhalation of **toluene**. Volatile radioactivity was observed in the placenta and fetuses immediately and up to 1 hr after inhalation of solvent at all stages of gestation. The fetal levels were, however, much lower than in maternal tissues. In early gestation, an even distribution pattern was observed, while the fetal liver reached a higher concn than other fetal tissues in late gestation. In similarity with maternal tissues, fetal tissues reached the highest levels of metabolites 30 min to 1 hr after inhalation. A retention in uterine fluid was seen at 4 hr. Otherwise no retention of metabolites was observed in the fetoplacental unit. No firmly tissue bound metabolites of the studied solvents were observed in the fetal tissues in late gestation, indicating no fetal capacity for formation of reactive metabolites.
[Ghantous H, Danielson BRG; Biol Res Pregnancy Perinatol 7 (3): 98-105 (1986)]**PEER REVIEWED**

A study was instituted to determine whether gavage dosing and inhalation exposure resulted in similar blood levels of **toluene**. Groups of male Sprague-Dawley rats were dosed with **toluene** either by gavage with 0.10, 0.25, 0.50, or 1.0 mg/kg/body weight or through exposure to atmospheres containing 200 to 1000 ppm **toluene**. Blood samples were taken at 0.5, 1.0, 2.0, 4.0, 6.0, and 24.0 hours following dosing. Steady state blood concentrations were reached for both inhaled doses within 30 minutes of the exposure. After 6 hours the steady state **toluene** blood concentrations for the 200 and 1000 ppm dose levels were 2.89 and 37.23 ppm, respectively. For the oral doses, the peak blood **toluene** concentration increased

with increasing dosage. Blood profiles from higher oral doses more closely approximated the steady state inhalation blood profiles. At 24 hours following dosing, blood **toluene** levels from all doses by either route were below detectable levels, suggesting minimal carry over of **toluene** concentrations from one day to the next. An equation was derived which will allow the gavage dose of **toluene** to be made equivalent to an inhalation dose. Based on results of other studies, it was suggested that blood **toluene** levels following sc injection more closely resemble those obtained following inhalation than do blood levels after gavage. However, it is possible to obtain blood concentrations of **toluene** similar to those generated by a 6 hour inhalation exposure to 1000 ppm through gavage dosing.
[Sullivan MJ, Conolly RB; Environ Research 45 (1): 64-70 (1988)]**PEER REVIEWED**

An investigation was carried out to quantitate the effect of pulmonary ventilation on uptake and biological concentrations of six organic solvents. Tested solvents were acetone, styrene, **toluene**, xylenes, methylchloroform, and tetrachloroethylene. Lung uptake and urinary concentration (Cu) were measured in 15 volunteers, 24 to 52 years old, exposed in a chamber for 2 or 4 hours at rest, 2 hours with three alternations of light exercise, 1 hour of light exercise, or 30 minutes or more strenuous exercise. Environmental levels and urinary concentration were measured in 528 occupationally exposed workers before and after 4 hours of work at a light task (pulmonary ventilation 12 to 18 liters per minute). For volunteers, uptake and urinary concentration values were significantly correlated. Environmental levels and urinary concentration showed a close relationship for occupational exposure. Biological equivalent exposure limits corresponding to threshold limit value (TLV) time weighted averages were derived from urinary concentration values. For acetone, styrene, and xylenes, uptake for a given time and exposure level was dependent only on ventilation. The **toluene** retention index was slightly lower for exercise than for rest, and uptake was ventilation dependent during rest and ventilation and retention index dependent during exercise. Retention indices decreased with increasing ventilation at rest and during exercise for tetrachloroethylene and methylchloroform. Their urinary concentration values were ventilation and retention index dependent. Methylchloroform uptake was higher during light versus heavy exercise. It was concluded that work load profoundly affects the absorbed amount of chemical and should be a factor in implementation of biological exposure indices and TLVs.

Animal studies indicate that **toluene** readily crosses the placenta.
[Ellenhorn, M.J., S. Schonwald, G. Ordog, J. Wasserberger. Ellenhorn's Medical Toxicology: Diagnosis and Treatment of Human Poisoning. 2nd ed. Baltimore, MD: Williams and Wilkins, 1997. 166]**PEER REVIEWED**

When dogs were exposed to 0.4-0.6 ug/ml **toluene** vapor, 91-94% was taken up in the lungs. Absorption was complete when **toluene** was given orally to dogs; the blood level in rats increased more slowly after oral administration than after inhalation. Absorption through the skin of mice in vivo was 4.50 ug/sq cm per hour. **Toluene** penetrated rat skin excised three days after clipping and depilation with cream at a rate one-tenth that of benzene and ten times that of ortho-xylene.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 93 (1989)]**PEER REVIEWED**

Toluene levels in brain and blood were linearly related to **toluene** levels in inhaled air after rats were exposed to 50, 100, 500, or 1000 ppm (189, 377, 1885, or 3770 mg/cu m) **toluene** for 3 hr.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 93 (1989)]**PEER REVIEWED**

When rabbits were given a single oral dose of 350 mg/kg bw **toluene**, 19% was exhaled unchanged within 12 hr.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 94 91989)]**PEER REVIEWED**

Pregnant C57B1 mice were exposed by inhalation to 14C-**toluene** (theoretical concentration, 2000 ppm (7540 mg/cu m)) for 10 min on days 11, 14 or 17 of gestation, and distribution of the label was determined 0, 0.5, 1, 4 and 24 hr after exposure. The label quickly entered the embryo, but uptake was low relative to that in maternal tissues. All fetal activity was extractable, indicating that no firmly bound metabolite was present.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 94 (1989)]**PEER REVIEWED**

In humans, up to 75% of inhaled **toluene** is metabolized to hippuric acid and excreted in the urine within 12 hr of exposure. The remainder of the **toluene** is mainly excreted unchanged with a small percent being excreted as a sulfate or glucuronide of cresol.

Exposure to **toluene** causes both reversible and irreversible changes in the central nervous system. The effects of **toluene** inhalation on some specific enzymes and glutamate and GABA receptor binding in defined parts of the rat brain were studied following several exposure schemes. The activities of the transmitter synthesizing enzymes glutamic acid decarboxylase (GAD), choline acetyltransferase (ChAT) and aromatic amino-acid decarboxylase (AAD) were used as markers for permanent loss of neuronal activity. Catecholaminergic neurons showed a 50% reduction in the brain stem after 4 weeks exposure to 250 and 1000 ppm **toluene**. Following 500 ppm of **toluene**, 16 hr/day for 3 months, a general increase in the activities was seen. This is most probably due to a reduction in total protein content, to which the activities were related. The neurotransmitters glutamate and GABA had their specific receptor binding increased in most of the brain areas studied, but decreased in some areas. The glial enzyme, glutamine synthetase, has its activity increased in the cerebellar hemisphere following 4 weeks exposure to 1000 ppm. This suggests that glial cells in the area may have proliferated, a frequent phenomenon following CNS damage.

The effect of styrene, **toluene**, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by

styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or **toluene** in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.

[Ungvary G et al; Teratology 27 (2): 261-9 (1983)]**PEER REVIEWED**

The metabolic interaction of **toluene** and ethanol was studied in male rabbits having received ethanol (26.0 mmol/kg po), **toluene** (5.4 mmol/kg po) or both. Compared with ethanol alone, **toluene** given 2 hr after ethanol caused a significantly higher and more prolonged concentration of blood alcohol. A similar trend of blood alcohol was observed at the later stage with **toluene** given prior to ethanol. On the other hand, with simultaneous doses of the two substances, the blood **toluene** concentration was higher for the first 15-30 min than the ethanol control and the urinary excretion of hippuric acid, a main metabolite of **toluene**, was markedly decreased for the first 2 hr. The blood ethanol in this group, on the contrary, was reduced until 1 hr after administration. These results indicate that **toluene** and ethanol act reciprocally as competitive inhibitors in their metabolism after single administrations.
[Takahashi S et al; Arch Toxicol 59 (5): 307-10 (1987)]**PEER REVIEWED**

In an experimental human study, the effect of **toluene** and ethanol (alone or in combination) on psychophysiologic functions was studied in 12 men (22-44 yr of age). Each subject served as his own control. Subjects were exposed to **toluene** by inhalation at a concentration of 300 mg **toluene**/cu m air for 4.5 hr. Ethanol was ingested at a dose equivalent to 15 mmol ethanol/kg body weight. **Toluene** had no significant effect on the 4 performance tests. A significant but weak depression of heart rate was observed during sleep latency tests (1-2.5 beats/min, $0.001 < p < 0.01$). There was a significant increase in reporting of headache ($p < 0.05$) and in reporting for all symptoms (nausea, headache, irritation) combined ($p < 0.05$). No interaction between ethanol and **toluene** was observed.
[Iregren A et al; Scand J Work Environ Health 12: 128-36 (1986)]**PEER REVIEWED**

Male Sprague-Dawley rats were used to study the renal toxicity potential of subchronic exposure to non-toxic doses of a combination of styrene and **toluene**. Four groups (n= 6) of rats were injected ip with: (1) 4 mmol styrene 2 times/day at 4 hr intervals; (2) 10 mmol **toluene**/kg once a day; (3) 4 mmol styrene/kg 2 times/day plus 10 mmol **toluene**/kg once/day; (4) All treatments were given 5 days/wk for 4 consecutive wk. By the fourth wk, there was a significant increase ($p < 0.05$) in urinary excretion of gamma-glutamyl transpeptidase, protein, and glucose by the group receiving combined treatment versus those receiving treatment with either chemical alone. There was an increase in excretion of hippuric acid in the mixture treatment group, but no increase in mandelic and phenylglyoxylic acids or thioethers. Blood urinary nitrogen was not modified by the individual chemicals or the mixture. Electron microscopic examination of the kidney showed an increase of single membrane vacuoles in the proximal convoluted tubules of rats treated with a mixture of chemicals, but not with **toluene** or styrene alone.

[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V71 842 (1999)]**PEER REVIEWED**

The aim of this study was to examine if the drug chlorzoxazone has any influence on the toxicokinetics of acetone and **toluene**. Chlorzoxazone is mainly metabolized by the same enzyme (Cytochrome P450 2E1) as ethanol and many other organic solvents. Ten male volunteers were exposed to solvent vapor (2 hr, 50 watt) in an exposure chamber. Each subject was exposed to acetone only (250 ppm), acetone + chlorzoxazone, **toluene** (50 ppm) only, **toluene** + chlorzoxazone, and chlorzoxazone only. Chlorzoxazone (500 mg) was taken as two tablets 1 h prior to solvent exposure. Samples of blood, urine and exhaled air were collected before, during and until 20 h post exposure. The time-concentration curves of acetone and **toluene** in blood were fitted to one- and four-compartment toxicokinetic models, respectively. Except for a delayed excretion of hippuric acid in urine, no effects on the **toluene** toxicokinetics were seen after chlorzoxazone treatment. Small increases in chlorzoxazone plasma levels were seen after exposure compared to chlorzoxazone alone. These interactions, although statistically significant, seem to be small compared to the interindividual variability on metabolism and toxicokinetics.

Metabolism/Metabolites:

Toluene is extensively metabolized via oxidation to benzyl alcohol then to benzaldehyde by alcohol dehydrogenase. Further oxidation then forms benzoic acid. Conjugation with glycine produces the major metabolite, hippuric acid, which is excreted in the urine. Benzyl glucuronide is formed in smaller amounts by conjugation with glucuronic acid.

The association between occupational **toluene** exposure and blood and adipose tissue **toluene** concentrations was examined. Breathing zone samples were monitored for **toluene** in two Swedish rotogravure printing facilities. Sc adipose tissues were taken from 37 workers after work on Thursday or Friday and analyzed for **toluene**. Venous blood samples were taken from 11 workers after work on Friday and at various times over the following weekend and assayed for **toluene**. Blood and adipose tissue samples were obtained from 11 other workers immediately after work and after 63 and 135 hours nonexposure and analyzed for **toluene**. Blood samples were also taken from 21 unexposed workers and analyzed for **toluene**. Attempts were made to fit the blood **toluene** data to various pharmacokinetics models. Airborne **toluene** concentrations in the printing factories ranged from 8 to 416 mg/cu m, median 75 mg/cu m. Blood **toluene** concentrations in the unexposed workers were below the detection limit, 0.01 umole/l. Blood samples obtained immediately after work contained 0.22 to 21.4 umole/l **toluene**. Elimination of **toluene** from the blood could be described by a three compartment model having median halftimes of 9 minutes, 2 hours, and 79 hours. **Toluene** was eliminated from adipose tissue with a median halftime of 79 hours. Adipose tissue concentrations were significantly associated with the workers' exposure to airborne **toluene** during the previous week. Adipose tissue **toluene** concentrations were significantly correlated with blood **toluene** concentrations after 70 hours exposure. It was concluded that the prolonged presence of **toluene** in the blood means that there is an endogenous exposure from adipose

tissue depots that continues long after occupational exposure has ended.
[Nise G et al; Br J Ind Med 46 (6): 407-11 (1989)]**PEER REVIEWED**

Evidence has suggested that there is an ethnic related difference in organic solvent metabolism in humans; analyses were thus made to obtain evidence of strain differences in animals to assist in consolidating the observation in workers. Female Donryu, Fischer, Sprague-Dawley, and Wistar rats were exposed to **toluene** at dose levels of 5, 45, 500, 2500, and 3500 ppm for 8 hours in a dynamic flow type exposure system. Urine samples were collected for 24 hours from the start of exposure. While the variation in free p-cresol excretion was wide among the rats of the same strain exposed to **toluene** at the same concentration, it was also noted that the four strains tested could be classified into two groups depending on the free p-cresol levels at **toluene** concentrations up to 500 ppm. No significant differences were noted between Sprague-Dawley and Wistar strains nor between Donryu and Fischer strains at the 45 and 500 ppm levels. However, there were significant differences between these two groups. At higher concentrations of 2500 and 3500 ppm, the increase in the free p-cresol levels was remarkable only in Donryu rats, reaching the levels of Sprague-Dawley and Wistar rats, while the level in Fischer rats remained unchanged.
[Inoue O et al; Bull Environ Contam Toxicol 43 (1): 74-9 (1989)]**PEER REVIEWED**

The mutual metabolic suppression between benzene and **toluene** was studied. The subjects, 190 male Chinese workers employed in shoe manufacturing, printing, audio equipment manufacture, and automobile industries, were divided into four groups based on occupational exposure: 65 were exposed to benzene, 35 to **toluene**, 55 to both compounds, and 35 served as comparisons. The arithmetic mean exposure level of benzene was 31.9 and of **toluene** 44.7 ppm. The mixture contained benzene at 17.9 +/29.3 and **toluene** at 20.5 +/25.8 ppm. The exposure levels were measured using individuals diffusive samplers. The geometric mean levels of the metabolites, phenol, catechol, hydroquinone, hippuric acid, and o-cresol, in unexposed workers were 6.9, 9.4, 4.8, 72.5, and 0.066 mg per liter, respectively. Values corrected for creatinine and specific gravity were different from the values cited above. Multiple correlation coefficients for benzene exposure versus its three metabolites were for phenol, 0.740; for catechol, 0.629; and for hydroquinone, 0.726. Multiple correlation coefficients for **toluene** and its two metabolites were 0.649 for hippuric acid and 0.583 for o-cresol. The slopes of regression lines for the exposure to benzene in the presence of **toluene** were less than half of those obtained when the workers were exposed to benzene alone; however, the regression lines for benzene in mixture versus catechol were about 80% or higher than the lines observed with benzene as the sole pollutant. The regression lines for **toluene** in the mixture and excretion level of hippuric acid and o-cresol showed reduced metabolic conversion compared to when exposure was limited to **toluene** alone. It was concluded that simultaneous exposure to benzene and **toluene** results in mutual suppression of metabolism yielding the urinary metabolites phenol, hydroquinone, hippuric acid, and o-cresol.

The urinary excretion of hippuric acid and o-cresol in humans was measured after a 7 hr exposure to **toluene** at a constant concn of 100 ppm but with a time-weighted avg of 100 ppm. In study A, 4 men were exposed to clean air and to constant and varying concns of **toluene** in combination with rest and with 100 W exercise for 140 min exercise increased the end-exposure excretion rate of hippuric acid and o-cresol by 47 and 114%, respectively. After exposure, all excess hippuric acid was excreted within 4 hr, while o-cresol was eliminated with a half-life of approx 3 hr. Alveolar air concn of **toluene** was 21-31 ppm during constant exposure and 13-57 ppm during varying exposure, but no difference in mean alveolar **toluene** concn or in metabolite excretion was seen between the exposure schedules. In study B, 32 men and 39 women aged between 31 and 50 yr were exposed once to either clean air or ... or varying concns of **toluene**. The background excretion rate of hippuric acid was 0.97 mg/min (1.25 g/g creatinine) and rose to 3.74 mg/min (3.90 g/g creatinine) during the last 3 hr of exposure to 100 pmm **toluene**. The corresponding figures for o-cresol were 0.05 ug/min (0.08 mg/g creatinine), and 2.04 ug/min (2.05 mg/g creatinine). The individual creatinine excretion rate was considerably influenced by sex, body wt, and smoking habits, thus influencing the metabolite concn standardized in relation to creatinine. Thus, both metabolites are estimates of **toluene** exposure; o-cresol is more specific than hippuric acid, but the individual variation in excretion of both metabolites is large, and when implementing either of them as biological exposure indexes, the influence of sex, body size, age as well as consumption of tobacco and alcohol has to be considered.
[Baelum J et al; Int Arch Occup Environ Health 59 (3): 281-94 (1987)]**PEER REVIEWED**

The distribution of radioactivity in pregnant mice was registered at different time intervals (0-24 hr) after a 10 min period of inhalation of **toluene**. ... Autoradiographic and liq scintillation methods were used to make possible the distinction between volatile, water sol, and firmly tissue bound radioactivity. **Toluene** reached high concns immediately after inhalation in lipid rich tissues (brain and fat) and well perfused organs (liver and kidney) but were rapidly eliminated resulting in low concns at 1 hr in all maternal tissues, except fat. Metabolites reached peak levels around 30 min to 1 hr after inhalation, but were also relatively rapidly eliminated. ... One exception was the very strong accumulation of water sol metabolites at 4 and 24 hr in the nasal mucosa and olfactory bulb after inhalation of **toluene**. Volatile radioactivity was observed in the placenta and fetuses immediately and up to 1 hr after inhalation of solvent at all stages of gestation. The fetal levels were, however, much lower than in maternal tissues. In early gestation, an even distribution pattern was observed, while the fetal liver reached a higher concn than other fetal tissues in late gestation. In similarity with maternal tissues, fetal tissues reached the highest levels of metabolites 30 min to 1 hr after inhalation. A retention in uterine fluid was seen at 4 hr. Otherwise no retention of metabolites was observed in the fetoplacental unit. No firmly tissue bound metabolites of the studied solvents were observed in the fetal tissues in late gestation, indicating no fetal capacity for formation of reactive metabolites.

A study was instituted to determine whether gavage dosing and inhalation exposure resulted in similar blood levels of **toluene**. Groups of male Sprague-Dawley rats were dosed with **toluene** either by gavage with 0.10, 0.25, 0.50, or 1.0 mg/kg/body weight or through exposure to atmospheres containing 200 to 1000 ppm **toluene**. Blood samples were taken at 0.5, 1.0, 2.0, 4.0, 6.0, and 24.0 hours following dosing. Steady state blood concentrations were reached for both inhaled doses within 30 minutes of the exposure. After 6 hours the steady state **toluene** blood concentrations for the 200 and 1000 ppm dose levels were 2.89 and 37.23 ppm, respectively. For the oral doses, the peak blood **toluene** concentration increased with increasing dosage. Blood profiles from higher oral doses more closely approximated the steady state inhalation blood profiles. At 24 hours following dosing, blood **toluene** levels from all doses by either route were below detectable levels, suggesting minimal carry over of **toluene** concentrations from one day to the next. An equation was derived which will allow the gavage dose of **toluene** to be made equivalent to an inhalation dose. Based on results of other studies, it was suggested that blood **toluene** levels following sc injection more closely resemble those obtained following inhalation than do blood levels after gavage. However, it is possible to obtain blood concentrations of **toluene** similar to those generated by a 6 hour inhalation exposure to 1000 ppm through gavage dosing.
[Sullivan MJ, Conolly RB; Environ Research 45 (1): 64-70 (1988)]**PEER REVIEWED**

An investigation was carried out to quantitate the effect of pulmonary ventilation on uptake and biological concentrations of six organic solvents. Tested solvents were acetone, styrene, **toluene**, xylenes, methylchloroform, and tetrachloroethylene. Lung uptake and urinary concentration (Cu) were measured in 15 volunteers, 24 to 52 years old, exposed in a chamber for 2 or 4 hours at rest, 2 hours with three alternations of light exercise, 1 hour of light exercise, or 30 minutes or more strenuous exercise. Environmental levels and urinary concentration were measured in 528 occupationally exposed workers before and after 4 hours of work at a light task (pulmonary ventilation 12 to 18 liters per minute). For volunteers, uptake and urinary concentration values were significantly correlated. Environmental levels and urinary concentration showed a close relationship for occupational exposure. Biological equivalent exposure limits corresponding to threshold limit value (TLV) time weighted averages were derived from urinary concentration values. For acetone, styrene, and xylenes, uptake for a given time and exposure level was dependent only on ventilation. The **toluene** retention index was slightly lower for exercise than for rest, and uptake was ventilation dependent during rest and ventilation and retention index dependent during exercise. Retention indices decreased with increasing ventilation at rest and during exercise for tetrachloroethylene and methylchloroform. Their urinary concentration values were ventilation and retention index dependent. Methylchloroform uptake was higher during light versus heavy exercise. It was concluded that work load profoundly affects the absorbed amount of chemical and should be a factor in implementation of biological exposure indices and TLVs.

[Fuxe K et al; Toxicol Lett 12 (2-3): 115-23 (1982)]**PEER REVIEWED**

Exposure to **toluene** causes both reversible and irreversible changes in the central nervous system. The effects of **toluene** inhalation on some specific enzymes and glutamate and GABA receptor binding in defined parts of the rat brain were studied following several exposure schemes. The activities of the transmitter synthesizing enzymes glutamic acid decarboxylase (GAD), choline acetyltransferase (ChAT) and aromatic amino-acid decarboxylase (AAD) were used as markers for permanent loss of neuronal activity. Catecholaminergic neurons showed a 50% reduction in the brain stem after 4 weeks exposure to 250 and 1000 ppm **toluene**. Following 500 ppm of **toluene**, 16 hr/day for 3 months, a general increase in the activities was seen. This is most probably due to a reduction in total protein content, to which the activities were related. The neurotransmitters glutamate and GABA had their specific receptor binding increased in most of the brain areas studied, but decreased in some areas. The glial enzyme, glutamine synthetase, has its activity increased in the cerebellar hemisphere following 4 weeks exposure to 1000 ppm. This suggests that glial cells in the area may have proliferated, a frequent phenomenon following CNS damage.
[Bjornaes S, Naalsund Lu; Toxicol 49 (2-3): 367-74 (1988)]**PEER REVIEWED**

The effect of styrene, **toluene**, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or **toluene** in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.

[Ungvary G et al; Teratology 27 (2): 261-9 (1983)]**PEER REVIEWED**

The metabolic interaction of **toluene** and ethanol was studied in male rabbits having received ethanol (26.0 mmol/kg po), **toluene** (5.4 mmol/kg po) or both. Compared with ethanol alone, **toluene** given 2 hr after ethanol caused a significantly higher and more prolonged concentration of blood alcohol. A similar trend of blood alcohol was observed at the later stage with **toluene** given prior to ethanol. On the other hand, with simultaneous doses of the two substances, the blood **toluene** concentration was higher for the first 15-30 min than the ethanol control and the urinary excretion of hippuric acid, a main metabolite of **toluene**, was markedly decreased for the first 2 hr. The blood ethanol in this group, on the contrary, was reduced until 1 hr after administration. These results indicate that **toluene** and ethanol act reciprocally as competitive inhibitors in their metabolism after single administrations.

[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V71 842 (1999)]**PEER REVIEWED**

The aim of this study was to examine if the drug chlorzoxazone has any influence on the toxicokinetics of acetone and **toluene**. Chlorzoxazone is mainly metabolized by the same enzyme (Cytochrome P450 2E1) as ethanol and many other organic solvents. Ten male volunteers were exposed to solvent vapor (2 hr, 50 watt) in an exposure chamber. Each subject was exposed to acetone only (250 ppm), acetone + chlorzoxazone, **toluene** (50 ppm) only, **toluene** + chlorzoxazone, and chlorzoxazone only. Chlorzoxazone (500 mg) was taken as two tablets 1 h prior to solvent exposure. Samples of blood, urine and exhaled air were collected before, during and until 20 h post exposure. The time-concentration curves of acetone and **toluene** in blood were fitted to one- and four-compartment toxicokinetic models, respectively. Except for a delayed excretion of hippuric acid in urine, no effects on the **toluene** toxicokinetics were seen after chlorzoxazone treatment. Small increases in chlorzoxazone plasma levels were seen after exposure compared to chlorzoxazone alone. These interactions, although statistically significant, seem to be small compared to the interindividual variability on metabolism and toxicokinetics.

The time-concentration curves of acetone and **toluene** in blood were fitted to one- and four-compartment toxicokinetic models, respectively. Except for a delayed excretion of hippuric acid in urine, no effects on the **toluene** toxicokinetics were seen after chlorzoxazone treatment. Small increases in chlorzoxazone plasma levels were seen after exposure compared to chlorzoxazone alone. These interactions, although statistically significant, seem to be small compared to the interindividual variability on metabolism and toxicokinetics.
[Ernstgard L et al; Toxicol Sci 48 (2): 189-96 (1999)]**PEER REVIEWED**

Minimum Fatal Dose Level:

Ingestion of approximately 60 ml (625 mg/kg) of **toluene** proved fatal for a while male mental patient.
[Ameno K et al; Forensic Sci Int 41: 255-60 (1989) as cited in U.S. Dept Health & Human Services/Agency for Toxic Substances & Disease Registry; Toxicological Profile for Toluene (Update) p.52 (1994) ATSDR/TP-93/14]**PEER REVIEWED**

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Toluene is released into the atmosphere principally from the volatilization of petroleum fuels and **toluene**-based solvents and thinners and from motor vehicle exhaust. **Toluene**'s production and use as an intermediate in the production of benzoic acid, benzaldehyde, benzene, explosives, dyes and many other organic compounds may also result in its release to the environment through various waste streams. **Toluene** has been detected in emissions from volcanos, forest fires and crude oil. If released to air, a vapor pressure of 28.4 mm Hg at 25 deg C indicates **toluene** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **toluene** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 3 days. **Toluene** may also be degraded in the atmosphere by reaction with nitrate radicals and ozone molecules, but these reactions are too slow to be environmentally important. If released to soil, **toluene** is expected to have high to moderate mobility based upon Koc values in the range of 37-178. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 6.64X10-3 atm-cu m/mole. **Toluene** may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation is expected to occur rapidly in soil surfaces, with half-lives in the range of several hours to 71 days. If released into water, **toluene** is not expected to adsorb to suspended solids and sediment based upon a Koc of 166 measured in lake sediment. Biodegradation is expected to occur rapidly in water, with reported half-lives of 4 and 56 days in aerobic and anaerobic water, respectively. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1 hour and 4 days, respectively. Measured BCF values of 13 and 90 in fish suggest bioconcentration in aquatic organisms is low to moderate. Hydrolysis is not expected to be an important environmental fate process for **toluene** due to lack of hydrolyzable functional groups. Exposure to **toluene** may occur occupationally during its production or subsequent use, particularly as a solvent or in gasoline, via dermal and respiratory routes. The main route of exposure for the general population will be through inhalation from contaminated air and handling of gasoline as well as ingestion of contaminated drinking water and food, and exposure to some consumer products. (SRC)
PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 1,625,598 workers (288,299 of these are female) are potentially exposed to **toluene** in the US(1). Occupational exposure to **toluene** may occur through inhalation and dermal contact with this compound at workplaces where **toluene** is produced or used(SRC). The general population may be exposed to **toluene** via inhalation of ambient air, ingestion of food and drinking water, handling of gasoline, and exposure to some consumer products where **toluene** is used as a solvent(SRC).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983)]**PEER REVIEWED**

Toluene was detected in hairdresser salons in Norway at concns of 0.04-0.11 mg/cu m(1). The time weighted average (TWA) of **toluene** in the workplace air of a municipal waste composting facility was reported as 188,000 ug/cu m(2). In a 1989 Danish survey on chemical exposures(3), the number of worker exposure events for **toluene** were documented: manufacturing of metals, 420; manufacturing of metal fabricated products 64,000; electrical machinery and apparatus, 1,500; manufacture of transport equipment 2,700; painters and carpenters 15,000; construction workers, 5,400; publishing and printing, 6,300; wholesale trades, 5,000; textile and leather manufacturing, 4,400; wood and furniture manufacturing, 5,900; manufacture of chemicals, 8,700; manufacture of paints and petroleum, 1,400; manufacture of non-metallic mineral products, 2,300; manufacture of optical instruments, 2,500 manufacture of plastic and boat building, 1,100; sewage and refuse disposal, 99; agriculture and forestry, 11,000; health services, 2,600. The total number of work related exposure events was 140,000(3). **Toluene** was detected in the workplace air of glass fiber manufacturing plants and high temperature sealing component and clutch lining plants at a mean concn of 65 ppm(4).

Environmental Biodegradation:

Toluene is readily degradable in a variety of standard biodegradability tests using sewage seed or sludge inoculums(1-7). Degradation has been observed in several die-away tests using seawater or estuarine water(9-12). The degradation rate is much faster in systems which have been contaminated by oil(9,10). Complete degradation has been observed in 4 days and 22 days in a marine mesocosm with summer and spring conditions, respectively(12), and 10 days in a 1% gas oil mixture in a North Sea coast water inoculum(8). A 90 day half-life in uncontaminated estuarine water was reduced to 30 days in oil-polluted water(10). The half-life in water collected near Port Valdez, Alaska was 12 days(9). 1.5 mM and 3 mM Ring-labeled **toluene** added to a methanogenic inoculum originally enriched from sewage sludge and incubated at 35 deg C for 60 days resulted in 3.6 and 4.5% 14-C final activity respectively(13).

Toluene completely degraded in groundwater in 8 days including a lag of 3-4 days while microbial populations became acclimated(1). Other investigators found that only 1-2% of **toluene** degraded in the subsurface environment(2) and >90% degraded in 4 weeks in soil cores at various depths both above and below the water table(3,5). Microbial attack proceeds via immediate hydroxylation of the benzene ring followed by ring-cleavage or oxidation of the side chain followed by hydroxylation and ring-cleavage(4).

Complete biodegradation of **toluene** was observed in lab microcosm tests during a 40 hour incubation period using soils previously exposed to **toluene**(1). **Toluene** was rapidly degraded in soil column experiments using acclimated soil at a rate of 8-35 mg/kg-day, and the rate followed zero-order kinetics(2). First-order degradation rate constants of 0.0005 to 0.0063 day-1 were measured for **toluene** in a gasoline-contaminated aquifer zone(3). These rate constants correspond to half-lives of 100-1,386 days(3). A first-order biodegradation rate constant of 0.045 day-1 was reported for **toluene** in an anaerobic petroleum contaminated aquifer, corresponding to a biodegradation half-life of 15 days(4). **Toluene** was rapidly biodegraded by indigenous mixed cultures in sandy aquifer material and pure cultures isolated from the aquifer(5). The zero-order rate constant for the aquifer material was 23 mg/l-day and had a lag period of 2 days(5). The half-life of **toluene** in aerobic and anaerobic water was reported as 4 and 56 days, respectively(6). The biodegradation half-life in various soils was reported as several hours to 71 days(7).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **toluene** with photochemically-produced hydroxyl radicals has been measured as 5.96X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 3 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1). The rate constant for the vapor-phase reaction of **toluene** with nitrate radicals has been measured as 6.8X10-17 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life

of about 491 days at an atmospheric concentration of 2.4X10+8 nitrate radicals per cu cm(2). The rate constant for the vapor-phase reaction of **toluene** with ozone has been measured as 4.1X10-22 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 27,950 days at an atmospheric concentration of 7X10+11 ozone molecules per cu cm(3). **Toluene** is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(4) nor to directly photolyze due to the lack of absorption in the environmental UV spectrum.

Soil Adsorption/Mobility:

In association with clay minerals, **toluene**'s adsorption is inversely proportional to the pH of the soil. Approximately 40-70% of **toluene** applied to the surface of sandy soils is volatilized.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 90 (1989)]**PEER REVIEWED**

The Koc of **toluene** was reported as 178 in a sandy soil(1) and as 37 (Wendover silty loam), 160 (Grimsby silt loam), 160 (Vaudreil sandy loam) and 46 (sandy soil)(2). The Koc of **toluene** in lake sediment was measured as 166(3). According to a classification scheme(4), this Koc data suggests that **toluene** is expected to have high to moderate mobility in soil.
[(1) Wilson JT et al; J Environ Qual 10: 501-6 (1981) (2) Nathwani JS, Phillips CR; Chemosphere 6: 157-62 (1977) (3) Kan AT et al; Environ Sci Technol 32: 892-902 (1998) (4) Swann RL et al; Res Rev 85: 17-28 (1983)]**PEER REVIEWED**

Volatilization from Water/Soil:

The Henry's Law constant for **toluene** is 6.64X10-3 atm-cu m/mole(1). This Henry's Law constant indicates that **toluene** is expected to volatilize rapidly from water surfaces(2). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec)(2) is estimated as 1 hour(SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec)(2) is estimated as 4 days(SRC). **Toluene**'s Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). **Toluene** may volatilize from dry soil surfaces based upon a vapor pressure of 28.4 mm Hg at 25 deg C(3).

Environmental Fate/Exposure Summary:

Toluene is released into the atmosphere principally from the volatilization of petroleum fuels and **toluene**-based solvents and thinners and from motor vehicle exhaust. **Toluene**'s production and use as an intermediate in the production of benzoic acid, benzaldehyde, benzene, explosives, dyes and many other organic compounds may also result in its release to the environment through various waste streams. **Toluene** has been detected in emissions from volcanos, forest fires and crude oil. If released to air, a vapor pressure of 28.4 mm Hg at 25 deg C indicates **toluene** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **toluene** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 3 days. **Toluene** may also be degraded in the atmosphere by reaction with nitrate radicals and ozone molecules, but these reactions are too slow to be environmentally important. If released to soil, **toluene** is expected to have high to moderate mobility based upon Koc values in the range of 37-178. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 6.64X10-3 atm-cu m/mole. **Toluene** may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation is expected to occur rapidly in soil surfaces, with half-lives in the range of several hours to 71 days. If released into water, **toluene** is not expected to adsorb to suspended solids and sediment based upon a Koc of 166 measured in lake sediment. Biodegradation is expected to occur rapidly in water, with reported half-lives of 4 and 56 days in aerobic and anaerobic water, respectively. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1 hour and 4 days, respectively. Measured BCF values of 13 and 90 in fish suggest bioconcentration in aquatic organisms is low to moderate. Hydrolysis is not expected to be an important environmental fate process for **toluene** due to lack of hydrolyzable functional groups. Exposure to **toluene** may occur occupationally during its production or subsequent use, particularly as a solvent or in gasoline, via dermal and respiratory routes. The main route of exposure for the general population will be through inhalation from contaminated air and handling of gasoline as well as ingestion of contaminated drinking water and food, and exposure to some consumer products. Environmental Biodegradation:

Toluene is readily degradable in a variety of standard biodegradability tests using sewage seed or sludge inoculums(1-7). Degradation has been observed in several die-away tests using seawater or estuarine water(9-12). The degradation rate is much faster in systems which have been contaminated by oil(9,10). Complete degradation has been observed in 4 days and 22 days in a marine mesocosm with summer and spring conditions, respectively(12), and 10 days in a 1% gas oil mixture in a North Sea coast water inoculum(8). A 90 day half-life in uncontaminated estuarine water was reduced to 30 days in oil-polluted water(10). The half-life in water collected near Port Valdez, Alaska was 12 days(9). 1.5 mM and 3 mM Ring-labeled **toluene** added to a methanogenic inoculum originally enriched from sewage sludge and incubated at 35 deg C for 60 days resulted in 3.6 and 4.5% 14-C final activity respectively(13).

Toluene completely degraded in groundwater in 8 days including a lag of 3-4 days while microbial populations became acclimated(1). Other investigators found that only 1-2% of **toluene** degraded in the subsurface environment(2) and >90% degraded in 4 weeks in soil cores at various depths both above and below the water table(3,5). Microbial attack proceeds via immediate hydroxylation of the benzene ring followed by ring-cleavage or oxidation of the side chain followed by hydroxylation and ring-cleavage(4).

Complete biodegradation of **toluene** was observed in lab microcosm tests during a 40 hour incubation period using soils previously exposed to **toluene**(1). **Toluene** was rapidly degraded in soil column experiments using acclimated soil at a rate of 8-35 mg/kg-day, and the rate followed zero-order kinetics(2). First-order degradation rate constants of 0.0005 to 0.0063 day-1 were measured for **toluene** in a gasoline-contaminated aquifer zone(3). These rate constants correspond to half-lives of 100-1,386 days(3). A first-order biodegradation rate constant of 0.045 day-1 was reported for **toluene** in an anaerobic petroleum contaminated aquifer, corresponding to a biodegradation half-life of 15 days(4). **Toluene** was rapidly biodegraded by indigenous mixed cultures in sandy aquifer material and pure

cultures isolated from the aquifer(5). The zero-order rate constant for the aquifer material was 23 mg/l-day and had a lag period of 2 days(5). The half-life of **toluene** in aerobic and anaerobic water was reported as 4 and 56 days, respectively(6). The biodegradation half-life in various soils was reported as several hours to 71 days(7).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **toluene** with photochemically-produced hydroxyl radicals has been measured as 5.96X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 3 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1). The rate constant for the vapor-phase reaction of **toluene** with nitrate radicals has been measured as 6.8X10-17 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 491 days at an atmospheric concentration of 2.4X10+8 nitrate radicals per cu cm(2). The rate constant for the vapor-phase reaction of **toluene** with ozone has been measured as 4.1X10-22 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 27,950 days at an atmospheric concentration of 7X10+11 ozone molecules per cu cm(3). **Toluene** is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(4) nor to directly photolyze due to the lack of absorption in the environmental UV spectrum.

Soil Adsorption/Mobility:

In association with clay minerals, **toluene**'s adsorption is inversely proportional to the pH of the soil. Approximately 40-70% of **toluene** applied to the surface of sandy soils is volatilized.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V47 90 (1989)]**PEER REVIEWED**

The Koc of **toluene** was reported as 178 in a sandy soil(1) and as 37 (Wendover silty loam), 160 (Grimsby silt loam), 160 (Vaudreil sandy loam) and 46 (sandy soil)(2). The Koc of **toluene** in lake sediment was measured as 166(3). According to a classification scheme(4), this Koc data suggests that **toluene** is expected to have high to moderate mobility in soil.

Volatilization from Water/Soil:

The Henry's Law constant for **toluene** is 6.64X10-3 atm-cu m/mole(1). This Henry's Law constant indicates that **toluene** is expected to volatilize rapidly from water surfaces(2). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec)(2) is estimated as 1 hour(SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec)(2) is estimated as 4 days(SRC). **Toluene**'s Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). **Toluene** may volatilize from dry soil surfaces based upon a vapor pressure of 28.4 mm Hg at 25 deg C(3).

RCRA Requirements:

U220; As stipulated in 40 CFR 261.33, when **toluene**, as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).
[40 CFR 261.33 (7/1/99)]**PEER REVIEWED**

F005; When **toluene** is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F005), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/99)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds

(VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Toluene** is produced, as an intermediate or a final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/99)]**PEER REVIEWED**

Listed as a hazardous air pollutant (HAP) generally known or suspected to cause serious health problems. The Clean Air Act, as amended in 1990, directs EPA to set standards requiring major sources to sharply reduce routine emissions of toxic pollutants. EPA is required to establish and phase in specific performance based standards for all air emission sources that emit one or more of the listed pollutants. **Toluene** is included on this list.
[Clean Air Act as amended in 1990, Sect. 112 (b) (1) Public Law 101-549 Nov. 15, 1990]**PEER REVIEWED**

Clean Water Act Requirements:

Toxic pollutant designated pursuant to section 307(a)(1) of the Federal Water Pollution Control Act and is subject to effluent limitations.
[40 CFR 401.15 (7/1/99)] **QC REVIEWED**

Toluene is designated as a hazardous substance under section 311(b)(2)(A) of the Federal Water Pollution Control Act and further regulated by the Clean Water Act Amendments of 1977 and 1978. These regulations apply to discharges of this substance. This designation includes any isomers and hydrates, as well as any solutions and mixtures containing this substance.
[40 CFR 116.4 (7/1/99)] **QC REVIEWED**

For the protection of human health from the toxic properties of **toluene** ... the ambient water criterion is determined to be 14.3 mg/l.
[USEPA; Quality Criteria for Water 1986: Toluene (1986) EPA 440/5-86-001] **QC REVIEWED**

The maximum contaminant level (MCL) set forth by the National Revised Primary Drinking Water Regulations for the organic contaminant **toluene** in community and non-transient, non-community water systems is 1 mg/l.

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Numbers. ... Isolate spill or leak area immediately for at least 50 to 100 meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs

Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, isolate for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or regular foam. Large fires: Water spray, fog or regular foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the

material(s) involved, and take precautions to protect themselves.

Recommendations for respirator selection. Condition: Emergency or planned entry into unknown concn or IDLH conditions: Respirator Class(es): Any self-contained breathing apparatus that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode. Any supplied-air respirator that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode in combination with an auxiliary self-contained breathing apparatus operated in pressure-demand or other positive-pressure mode.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 310]**PEER REVIEWED**

Recommendations for respirator selection. Condition: Escape from suddenly occurring respiratory hazards: Respirator Class(es): Any air-purifying, full-facepiece respirator (gas mask) with a chin-style, front- or back-mounted organic vapor canister. Any appropriate escape-type, self-contained breathing apparatus.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 310]**PEER REVIEWED**

Preventive Measures:

Drench-type showers, eye-wash fountains should be installed and maintained to provide prompt, immediate access.
[NIOSH; Criteria Document: Toluene p.9 (1973) DHEW Pub. NIOSH 73-11023]**PEER REVIEWED**

Open lights or other agencies liable to ignite the vapor should be excluded from areas where the liquid is liable to be exposed in use or by accident.
[International Labour Office. Encyclopedia of Occupational Health and

Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 2185]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **toluene**/. ... Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents are highly flammable.
[Hart C; J Environ Health 49 (5): 282-86 (1987)]**PEER REVIEWED**

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 310]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to knock-down vapors.

Cleanup Methods:

Eliminate all ignition sources. Stop or control the leak, if this can be done without undue risk. Use water spray to cool and disperse vapors and protect personnel. Absorb in noncombustible material for proper disposal. Control runoff and isolate discharged material for proper disposal.
[Fire Protection Guide to Hazardous Materials. 12 ed. Quincy, MA: National Fire Protection Association, 1997.,p. 49-197]**PEER REVIEWED**

1. REMOVE ALL IGNITION SOURCES. 2. VENTILATE AREA OF SPILL OR LEAK. 3. FOR SMALL QUANTITIES, ABSORB ON PAPER TOWELS. EVAPORATE IN SAFE PLACE (SUCH AS FUME HOOD). ALLOW SUFFICIENT TIME FOR EVAPORATING VAPORS TO COMPLETELY CLEAR HOOD DUCTWORK. BURN PAPER IN SUITABLE LOCATION AWAY FROM COMBUSTIBLE MATERIALS.
[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981. 4]**PEER REVIEWED**

Fluorocarbon water foam may be used to diminish vapors and provide wet down.
[Environment Canada; Tech Info for Problem Spills: Toluene (Draft) p.94 (1982)]**PEER REVIEWED**

Cellosive and hycar absorbent materials, may be used for vapor suppression and/or containment of **toluene**.
[Environment Canada; Tech Info for Problem Spills: Toluene (Draft) p.94 (1982)]**PEER REVIEWED**

Treat contaminated water by gravity separation of solids, followed by skimming of surface. Pass through dual media filtration and carbon adsorption units (carbon ratio 1.0 kg to 10.0 kg soluble material). Return waste water from backwash to gravity separator.
[Environment Canada; Tech Info for Problem Spills: Toluene (Draft) p.94 (1982)]**PEER REVIEWED**

Environmental considerations - Land Spill: Dig a pit, pond, lagoon, holding area to contain liquid or solid material. /SRP: If time permits, pits, ponds, lagoons, soak holes, or holding areas should be sealed with an impermeable flexible membrane liner./ Dike surface flow using soil, sand bags, foamed polyurethane, or foamed concrete. Absorb bulk liquid with fly ash, cement powder,or commercial sorbents. Apply "universal" gelling agent to immobilize spill. Apply appropriate foam to diminish vapor and fire hazard.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

Environmental considerations - Water Spill: Use natural barriers or oil spill control boom to limit spill travel. Use surface active agent (eg Detergent, soaps, alcohols), if approved by EPA. Inject "universal" gelling agent to solidify encircled spill and increase effectiveness of booms. If dissolved, in region of 10 ppm or greater concentration, apply activated carbon at ten times the spilled amount. Remove trapped material with suction hoses. Use mechanical dredges or lifts to remove immobilized masses of pollutants and precipitates.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

Environmental considerations - Air Spill: Apply water spray or mist to knock down vapors.
[Association of American Railroads. Emergency Handling of Hazardous

Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

Disposal Methods:

Generators of waste (equal to or greater than 100 kg/mo) containing this contaminant, EPA hazardous waste numbers U220, and F005 must conform with USEPA regulations in storage, transportation, treatment and disposal of waste.
[40 CFR 240-280, 300-306, 702-799 (7/1/90)]**PEER REVIEWED**

Toluene is a waste chemical stream constituent which may be subjected to ultimate disposal by controlled incineration.
[USEPA; Engineering Handbook for Hazardous Waste Incineration p.2-9 (1981) EPA 68-03-3025]**PEER REVIEWED**

A good candidate for liquid injection incineration at a temperature range of 650 to 1,600 deg C and a residence time of 0.1 to 2 seconds. A good candidate for rotary kiln incineration at a temperature range of 820 to 1,600 deg C and residence times of seconds for liquids and gases, and hours for solids. A good candidate for fluidized bed incineration at a temperature range of 450 to 980 deg C and residence times of seconds for liquids and gases, and longer for solids.
[USEPA; Engineering Handbook for Hazardous Waste Incineration p.3-16 (1981) EPA 68-03-3025]**PEER REVIEWED**

Additional flammable solvent may be added to increase incineration efficiency. Following treatment at a spill site or waste management facility, the resultant sludge can be disposed of to a secure landfill.
[Environment Canada; Tech Info for Problem Spills: Toluene (Draft) p.96 (1982)]**PEER REVIEWED**

LARGE QUANTITIES CAN BE RECLAIMED OR COLLECTED & ATOMIZED IN SUITABLE COMBUSTION CHAMBER. **TOLUENE** SHOULD NOT BE ALLOWED TO ENTER A CONFINED SPACE, SUCH AS SEWER, BECAUSE OF POSSIBILITY OF EXPLOSION. ... DISPOSAL METHODS: **TOLUENE** MAY BE DISPOSED OF BY ATOMIZING IN SUITABLE COMBUSTION CHAMBER.

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Numbers. ... Isolate spill or leak area immediately for at least 50 to 100 meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-130]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or regular foam. Large fires: Water spray, fog or regular foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-130]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Open lights or other agencies liable to ignite the vapor should be excluded from areas where the liquid is liable to be exposed in use or by accident.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 2185]**PEER REVIEWED**

A major concern in the painting studio is solvents, /including **toluene**/. ... Precautions include ... use of dilution and local exhaust ventilation, control of storage areas, disposal of solvent soaked rags in covered containers, minimizing skin exposure and the use of respirators and other personal protective equipment. The control of fire hazards is also important, since many of the solvents are highly flammable.
[Hart C; J Environ Health 49 (5): 282-86 (1987)]**PEER REVIEWED**

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 310]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames, and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to knock-down vapors.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

Personnel protection: Avoid breathing vapors. Keep upwind. ... Do not handle broken packages unless wearing appropriate personal protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous

Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

If material leaking (not on fire): Consider evacuation from downwind area based on amount of material spilled, location and weather conditions.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 1057]**PEER REVIEWED**

The worker should immediately wash the skin when it becomes contaminated.

[American Conference of Governmental Industrial Hygienists. TLVs and BEIs. Threshold Limit Values for Chemical Substances and Physical Agents and Biological Exposure Indices. Cincinnati, OH. 2000. 67]**QC REVIEWED**

Biological Exposure Index (BEI): Hippuric acid in urine at end of shift is 1.65 g/g creatinine. The determinant is usually present in a significant amt in biological specimens collected from subjects who have not been occupationally exposed. Such background levels are incl in the BEI value. The determinant is nonspecific, since it is observed after exposure to some other chemicals. These nonspecific tests are preferred because they are easy to use and usually offer a better correlation with exposure than specific tests. In such instances, a BEI for a specific, less quantitative biological determinant is recommended as a confirmatory test.

Laboratory Methods:

Clinical Laboratory Methods:

NIOSH Method: 8002. Analyte: **Toluene**. Specimen: Venous blood, after 2 or more hours of exposure. Procedure: Gas chromatography, hydrogen-air flame ionization detector. The precision/RSD is 0.098 (1 ug/ml blood) and the recovery is 0.93 @ 2 ug/ml blood. The working range is 1 to 600 ug/ml. Applicability: **Toluene** is commonly found in trace amounts in humans working in the paint spray industry. Interferences: Ethanol in excess of the stated range increased blood **toluene** concentration. When substances other than the analytes are present in the blood, record their identities to determine possible interferences.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 8002-1]**PEER REVIEWED**

A procedure for the determination of **toluene** in blood by the purge and trap method is described ... has a linear range which extends up to at least 1500 ug/l ... detection limit ... is estimated to be less than 7.5 ug/l ...
[Cocheo V et al; Am Ind Hyg Assoc 43 (12): 938-41 (1982)]**PEER REVIEWED**

An automated high performance liquid chromatographic method for the direct determination of urinary concentrations of p-methylhippuric acids, and metabolites of **toluene** is described. A mixed solution of 5 mM potassium phosphate monobasic/acetonitrile (90/10) was used as a mobile phase . The method is simple and specific. Urine can be analyzed without solvent extraction.
[Ogata M, Taguchi T; Int Arch Occup Environ Health 59 (3): 263-72 (1987)]**PEER REVIEWED**

Analytic Laboratory Methods:

Quantitative determination of 4 to 40 ppm **toluene** in water with precision of 10% using IR spectroscopy.
[Amer Water Works Assoc; Standard Methods for the Examination of Water and Waste Water 14th Ed (1976)]**PEER REVIEWED**

Quantitative method for detection of **toluene** in water by gas chromatography. Levels over 1 ppm can be detected.
[Amer Water Works Assoc; Standard Methods for the Examination of Water and Waste Water 14th Ed (1976)]**PEER REVIEWED**

TOLUENE WAS IDENTIFIED IN WASTE-CONTAMINATED SOIL AND CHEMICAL STILL BOTTOM EXTRACTS BY GC/FOURIER TRANSFORM INFRARED SPECTROMETRY.
[GURKA DF, BETOWSKI LD; ANAL CHEM 54: 1819 (1982)]**PEER REVIEWED**

TWENTY AQ INDUST EFFLUENTS CONTAINING POLLUTANTS WERE ANALYZED USING ISOTOPE DILN & GC/MASS SPECTROMETRY. **TOLUENE** WAS ONE OF THE POLLUTANTS. [COLBY BN ET AL; INTERNATIONAL ENVIRONMENT & SAFETY FEB: 8 (1982)]**PEER REVIEWED**

NIOSH Method 1500. Analyte: **Toluene**. Matrix: Air. Procedure: Gas chromatography hydrogen-air flame ionization detector. For **toluene** this method has an estimated detection limit of 0.001 to 0.01 mg/sample with capillary column/sample. The overall precision/RSD is 0.011. Applicability: This method is intended for determining the OSHA-regulated hydrocarbons included within the boiling point range of n-pentane through n-octane. Interferences: At high humidity, breakthrough volumes may be reduced by as much as 50%.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 1500-1]**PEER REVIEWED**

NIOSH Method 4000. Analyte: **Toluene**. Procedure: Gas chromatography, hydrogen-air flame ionization detector. For **toluene** this method has an estimated detection limit of 0.01 mg/sample. The overall precision/RSD is 0.022. Applicability: The working range is 13 to 660 ppm (50 to 2500 mg/cu m) for a 4 hr sample. Interferences: None identified.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 4000-1]**PEER REVIEWED**

NIOSH Method 1501. Analyte: **Toluene**. Matrix: Air. Procedure: Gas chromatography, hydrogen-air flame ionization detector. For **toluene** this method has an estimated detection limit of 0.001 to 0.01 mg/sample with capillary column/sample. The overall precision/RSD is 0.011. Applicability: This method is for peak, ceiling and TWA determinations of aromatic hydrocarbons. Interferences: Use of the recommended column will prevent interferences by alkanes (less or equal to C10).
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 1501-1]**PEER REVIEWED**

EPA Method 524.1. Purge-and-Trap Gas Chromatography/Mass Spectrometry. The method is applicable for the determination of volatile organic compounds in water, finished drinking water, raw source water, or drinking water in any treatment stage. For **toluene** the method has a detection limit of 0.08 ug/l and a standard deviation of 4.1%.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 524.2. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the determination of volatile aromatic compounds in water including finished drinking water, raw source water, and drinking

water in any treatment stage. For **toluene** the method has a detection limit of 0.11 ug/l and a relative standard deviation of 8.0% with a wide bore capillary column, and a method detection limit of 0.08 ug/l and a relative standard deviation of 5.9% with a narrow bore capillary column.
[USEPA; Methods for the Determinatioon of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 602. Purge-and-Trap Gas Chromatography with photoionization detection for the determination of purgeable aromatics including **toluene** in municipal and industrial discharges. Under the prescribed conditions for **toluene** the detection limit is 0.2 ug/l. The method is applicable for use in the concentration range from the method detection limit to 100 times that limit. Precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of the sample matrix.
[40 CFR 136 97/1/91)]**PEER REVIEWED**

EPA Method 624. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the analysis of purgeable organics including **toluene** in the municipal and industrial discharges. Under the prescribed conditions, for **toluene** the method has a detection limit of 6.0 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 1624. Isotope Dilution Purge-and-Trap Gas Chromatography/Mass Spectrometry. This method is applicable for the determination of volatile organic compounds in municipal and industrial discharges. By adding a known amount of a labeled compound to every sample prior to purging, a correction of recovery of the pollutant can be made. If labeled compounds are not available, an internal standard method is used. Under the prescribed conditions, for both the labeled, and unlabeled ethylbenzene the method has a minimum detection level 10 ug/l.The established acceptance performance criteria at 20 ug/l is 6.2 ug/l for the standard deviation of the recovery, with the average recovery of 14.5 to 28.7 ug/l and the labeled cmpd recovery ranging from 4 to 193%.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 8020. Direct Injection or Purge-and-Trap Gas Chromatograpy with photoionization detection for the determination of aromatic volatile organics including **toluene** in solid waste. Under the prescribed conditions, for **toluene** the method has a detection limit of 0.2 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[USEPA; Test Methods for Evaluating Solid Waste SW-846 (1986)]**PEER REVIEWED**

EPA Method 8240. Gas Chromatography/Mass Spectrometry for the determination of volatile Organics. This method can be used to quantify most volatile organic compounds including **toluene** that have boiling points below 200 deg C and are insoluble or slightly soluble in water. The detection limit is not given. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[USEPA; Test Methods for Evaluating Solid Waste SW-846 (1986)]**PEER REVIEWED**

EPA Method 502.2: Purge-and-Trap Capillary Column Gas Chromatography with Photoionization and

Electrolytic Conductivity Detectors in Series. The method is applicable for the determination of volatile organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For **toluene** the method has a detection limit of 0.01 ug/l, a percent recovery of 99%, and a standard deviation of 1.9 using the photoionization detector.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 502.1. Purge and Trap Gas Chromatography with a halogen-specific detector for the determination of halogenated volatile compounds including **toluene** in finished drinking water, raw source water, or drinking water in any treatment stage. Under the prescribed conditions for **toluene**, the method detection limit is 0.02 ug/l.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

TOLUENE DIISOCYANATE

CASRN: 26471-62-5

For other data, click on the Table of Contents

Human Toxicity Excerpts:

The presence of different thresholds on bronchial reactivity to **toluene** diisocyanate was tested in 20 spray painters employed in the furniture industry and affected by TDI induced asthma. Bronchial provocation tests failed to demonstrate nonspecific hyperreactivity to methacholine. Exposure of the workers to **toluene** diisocyanate in concentrations ranging from 0.02 to 0.25 ppm demonstrated the occurrence of low, moderate and high thresholds of airways response to **toluene** diisocyanate in nine, seven and four patients, respectively. There was no association between the **toluene** diisocyanate response threshold and the positive response pattern to the lower range of **toluene** diisocyanate levels, but six of the nine patients with low threshold of response to **toluene** diisocyanate and six of the 11 patients with moderate or high thresholds had nonspecific bronchial hyperreactivity. The response to **toluene** diisocyanate also was not associated with the duration of the asthmatic condition, smoking, cessation of work or nonspecific response to methacholine. The pattern of response was not dose dependent in ten of 13 patients who had two positive bronchial provocation tests with different levels of **toluene** diisocyanate, although dual responses were recorded in three patients who had late reactions at low concentrations of **toluene** diisocyanate. The value of forced expiratory volume in one second, recorded during immediate reactions, showed a dose response relationship, in that it declined by 28.4% at lower **toluene** diisocyanate levels as compared to 38.3% following inhalation of higher doses of the compound; no such association was established for the late reaction to **toluene** diisocyanate. The results conclude that patients who are sensitive to **toluene** diisocyanate may have different thresholds of response to the agent.

[Paggiaro PL et al; Respiration 50 (3): 167-73 (1986)]**PEER REVIEWED**

TOLUENE DIISOCYANATE

CASRN: 26471-62-5

Non-Human Toxicity Excerpts:

Groups of 50 F344/N rats of each sex and 50 B6C3F1 mice of each sex were gavaged with corn oil or a mixture of **toluene** diisocyanate in corn oil for 5 days per wk for 105 or 106 wk. Female rats and mice were given doses of 60 or 120 mg/kg body weight, while male rats received 30 or 60 mg/kg, and male mice received 120 or 240 mg/kg. The **toluene** diisocyanate reacted with the moisture in the corn oil vehicle resulting in doses that were 10% to 23% below the target dose concn. The chemical product used was commercial grade **toluene** diisocyanate, which was an 80%-20% mixture of the 2,4- and 2,6-isomers. Chemical disposition and metabolism studies were conducted with each of the radiolabelled **toluene** diisocyanate isomers in male rats. Absorption of both of the **toluene** diisocyanate isomers occurred, with the highest concn found in the stomach, cecum, large intestine, and bladder. Excretion occurred via the feces and urine. The major metabolic products from the metabolism of 2,4-**toluene** diisocyanate were shown to be identical with those from the metabolism of the carcinogen, 2,4-diaminotoluene, whereas the metabolism of the 2,6-**toluene** diisocyanate isomer yielded one major product, identified as 2,6-bis(acetylamino)**toluene**. Greater than 10% depression in body weight gain occurred in all dosed groups of rats throughout most of the study. The major non-neoplastic lesions that were observed in both sexes of the **toluene** diisocyanate exposed rats were dose related incr in acute broncho-pneumonia, characterized as chemical pneumonitis, with incidences as high as 50%. In mice mean body weight gain was depressed in dosed male and in high dose females. The principle non-neoplastic lesion in mice that was attributed to chemical treatment was cytomegaly of the kidney tubular epithelium in males. Survival in all groups of dosed rats was significantly lower than in controls. A dose-dependent pattern of mortality did not commence until 70 wk of exposure, demonstrating that **toluene** diisocyanate elicited a cumulative toxic response. There was also significantly lower survival in high dose male, but not female mice, by comparison to controls. Despite the reduction of power and sensitivity in the rat studies caused by early mortality, statistically significant incr in tumor incidences were observed in many different target organs. **Toluene** diisocyanate was carcinogenic in F344/N rats, causing sc fibromas and fibrosarcomas in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland tumors in females.

Human Toxicity Excerpts:

Two men were exposed to **toluene** diisocyanate atmospheres at three different air concn (ca 25, 50 and 70 ug/cu m). The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8-cu m stainless-steel test chamber. The effective exposure period was 4 hr. The isomeric composition of the air in the test chamber was 30% 2,4-**toluene** diisocyanate and 70% 2,6-**toluene** diisocyanate. The concn of **toluene** diisocyanate in air of the test chamber was determined by an HPLC method using the 9-(N-methyl-amino-methyl)-anthracene reagent and by a continuous-monitoring filter-tape instrument. Following the hydrolysis of plasma and urine, the related amines, 2,4-toluenediamine and 2,6-toluenediamine, were determined as pentafluoropropionic anhydride derivatives by capillary gas chromatography using selected ion monitoring in the electron impact mode. In plasma, 2,4- and 2,6-toluenediamine showed a rapid-phase elimination half-time of ca 2-5 hr, and that for the slow phase was greater than 6 days. A connection was observed between concn of 2,4- and 2,6-**toluene** diisocyanate in air and the levels of 2,4- and 2,6-toluenediamine in plasma. The cumulated amount of 2,4-toluenediamine excreted in the urine over 24 hr was ca 15%-19% of the estimated inhaled dose of 2,4-**toluene** diisocyanate, and that of 2,6-toluenediamine was ca 17%-23% of the inhaled dose of 2,6-**toluene** diisocyanate. A connection was found between the cumulated (24 hr) urinary excretion of 2,4- and 2,6-toluenediamine and the air concn of 2,4- and 2,6-**toluene** diisocyanate in the test chamber.

Non-Human Toxicity Excerpts :

Groups of guinea pigs were exposed, via inhalation, to **toluene** diisocyanate concentrations ranging from 0.12 to 10 ppm. Exposure was for 3 hr/day on 5 consecutive days. Beginning on day 22, animals were evaluated for **toluene** diisocyanate specific antibodies, skin sensitivity, and pulmonary sensitivity to **toluene** diisocyanate. No antibodies were detected in animals exposed to 0.12 ppm **toluene** diisocyanate, whereas 55% of animals exposed to 0.36 ppm **toluene** diisocyanate or greater displayed **toluene** diisocyanate specific antibodies in their sera. Exposure to higher **toluene** diisocyanate concentrations resulted in both a greater percentage of animals producing antibodies and higher antibody titers. Pulmonary sensitivity, assessed by bronchial provocation challenge with **toluene** diisocyanate protein antigen, was not detected in animals exposed to 0.12 ppm **toluene** diisocyanate but was present in guinea pigs exposed to **toluene** diisocyanate concentrations of 0.36 ppm or greater. However, exposure concentrations higher than 2 ppm were pneumotoxic and resulted in few pulmonary hyprsensitivity reactions. Exposure of animals to 0.02 ppm **toluene** diisocyanate for 15 weeks did not result in either dermal sensitivity, pulmonary sensitivity, or production oftoluene diisocyanate specific antibody. The exposure protocol, as well as the exposure concentration, was important for establishment of sensitivity. Recognition of the concentration-response relationship governing immune reaction to inhaled **toluene** diisocyanate should permit establishment of safe airborne exposure levels for industrial workers to prevent sensitization. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

Ten sensitized subjects, previously shown to develop a dual or late asthmatic reaction after inhaling **toluene** diisocyanate were examined. In each subject, forced expiratory volume in one second was measured and venous blood was taken before, and 30 minutes and eight, 24, 48, and 72 hours after exposure to **toluene** diisocyanate (0.005-0.05 ppm for 10-30 minutes). Filtered air was used as a control. Differential leukocyte counts were determined and phenotypic analysis was performed by immunofluorescene on mononuclear cells using monoclonal antibodies

(anti-CD3, anti-CD4, anti-CD8, and anti-HLA-DR). Five subjects developed a dual asthmatic reaction and five had a late reaction. Percentage of CD8 positive lymphocytes increased significantly eight hours after exposure to **toluene** diisocyanate (from 27 plus or minus 3 (SEM) % to 42.1 plus or minus 5%) in the subjects with an isolated late reaction. A delayed significant further increase in suppressor/cytotoxic T lymphocytes was seen in seven of the 10 subject 48 hours after active exposure (from 27 plus or minus 2% to 22 plus or minus 4.8%), irrespective of the type of asthmatic reaction developed after exposure to **toluene** diisocyanate. Eosinophil percentage increased from 2.5% plus or minus 1.0 to 6.4 plus or minus 1.2 24 hours after exposure to **toluene** diisocyante and the increase was sustained for up to 48 hours (4.7 plus or minus 1.1). No significant variations of forced expiratory volume in one second or cell percentages were seen in the controls. In conclusion, the events triggered by exposure to **toluene** diisocyante in sensitised subjects included changes in lung function and systemic effects which lasted longer than bronchoconstriction and concerned suppressor/cytotoxic lumphocytes and eosinophils. These results suggest that **toluene** diisocyanate induced late asthmatic reactions may be associated with an immunological response to **toluene** diisocyanate or to its products. /**Toluene** diisocyanate/

Probable Routes of Human Exposure :

29,284 Workers are potentially exposed to 2,4-**toluene** diisocyanate based on statistical estimates derived from the NIOSH Survey conducted in 1972-1974 in the USA(1). This survey sampled 5000 businesses in 67 metropolitan areas throughout the US for the manufacture and use of chemicals, trade name products known to contain the compound and generic products suspected of containing the compound. 514 Workers are potentially exposed to 2,4-**toluene** diisocyanate based on statistical estimates derived from the NIOSH Survey conducted in 1981-1983 in the USA(2). Since the NOES survey excludes exposure to trade name chemicals which may contain the chemical, occupational exposure should be considerably higher(SRC). Airborne **toluene** diisocyanate in two plants producing flexible polyurethane foam for use in matresses, carpet pads, and air filters by a continuous slab process were determined(3). In this process the starting materials are mixed internally in a foaming nozzle and is poured onto moving kraft paper at which time the material foams and heats up (mixing end). The foam slab is then carried into a ventilated curing tunnel during which time the unreacted TDI and other material is driven off due to the high internal temperature (finishing end). The paper liner is subsequently stripped off and the slab cut into pieces. Concentration medians for 2,4-**toluene** diisocyanate were 0.70 and 0.33 ppb for the mixing and finishing ends, respectively(3). Only an insignificant number of samples exceeded the 20 ppb ceiling recommended by the ACGIH(3). In a similar Finish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(4). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(4). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4- isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(4). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(4).

Non-Human Toxicity Excerpts :

Acetylcholinesterase activity was measured in bronchial tissue homogenate and blood from rats subjected to single and repeated 4 hr daily inhalation exposure to **toluene** diisocyanate or control atmospheres. A single 4 hr exposure to **toluene** diisocyanate in the concentration range of 0.7-4.3 ppm did not decrease AChE activity in bronchial tissue but a 4 hr exposure to 0.6 ppm **toluene** diisocyanate, or greater, for two consecutive days did reduce this activity (19% to 33% of the controls). Increasing the level of exposure to **toluene** diisocyanate for two consecutive days from 0.6 to 4.0 ppm and extending the length of exposure to 1.2 ppm **toluene** diisocyanate from 2 to 4, 9 or 14 days produced no further decrease in bronchial ACHE activity.

Throughout these experiments, blood AChE activity remained unchanged. In rats exposed to 0.3 or 1 ppm **toluene** diisocyanate for 3 weeks, staining of the bronchial smooth muscle for AChE was reduced (36% of the controls) after exposure to 1 ppm **toluene** diisocyanate. These results support, for the first time, in vivo and localized anti-AChE activity by TDI. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint material containing **toluene** diisocyanate. His symptoms (non-productive cough, dyspnea on exertion, and intermittent fever) began 6 to 8 hr after exposure to **toluene** diisocyanate and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate human serum albumin was present in bronchoalveolar lavage fluid and sera; IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate human serum albumin. The histologic findings from a bronchial biopsy, showed an acute exudative reaction; the presence of alveolar edema and lymphocytic infiltrates in alveolar and bronchiolar walls, which suggested hypersensitivity pneumonitis. Bronchoalveolar lavage, which was repeated on four separate occasions showed lymphocytosis and a predominance of suppressor cytotoxic T cells. Findings from serial determination of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to **toluene** diisocyanate. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

A case of building-related health complaints among 14 full-time employees and 1 part-time employee was investigated with respect to the relationship among frequency of symptoms (involving eyes, nose, sinuses, throat, lung, skeletomuscular system, and central nervous system) and antibodies to human serum albumin conjugates of **toluene** diisocyanate. Antibody testing was done by the ELISA procedure. Employees noted the presence or absence of symptoms by filling in questionnaires. Anti-**toluene** diisocyanate isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. Antibody titers were positively but not significantly correlated with % of total symptoms as follows: **toluene** diisocyanate-IgG (r= 0.48), **toluene** diisocyanate-IgG (r= 0.55). Anti-**toluene** diisocyanate human serum albumin IgE titers were neg in 7 subjects and pos in 5. Anti-**toluene** diisocyanate human serum albumin-IgG antibodies were detected in all employees tested. /**Toluene** diisocyanate/

Non-Human Toxicity Excerpts :

Toluene diisocyanate, a polymerizing agent used in production of plastics, can cause airway disease in some exposed individuals. Using guinea pigs as a model, the response of the airways and the type II cells of the peripheral lung was monitored morphologically and morphometrically after exposure to **toluene** diisocyanate vapors at 30 ppb, 260 ppb, and 3100 ppb. The two low doses of **toluene** diisocyanate caused little change in airways epithelium. There was not gross inflammatory cell infiltrate, however, surface infoldings and intracellular ciliated cysts increased in numbers. Animals exposed to 3100 ppb **toluene** diisocyanate 4 hr/day for 5 days, sustained considerable damage to the epithelium, and stratified nonkeratinizing cells lined the airways until ine week after exposure. Polymorphonuclear leukocytes were present in the early period after exposure. Increased numbers of eosinophils were present between one and two weeks following exposure. Mitoses in the epithelium were common during recovery. In the peripheral lung, though a modest subjective increase in the number of type II cells was seen after 3100 ppb **toluene** diisocyanate, the volume density of type II cells, and organellar

Non-Human Toxicity Excerpts :

Guinea pigs were exposed by head only inhalation for 5 hr to concentrations of approximately 1 ppm of tolylene diisocyanate and 14 days later pinnal application of **toluene** diisocyanate on 3 consecutive days was followed by a dermal application of **toluene** diisocyanate after a further 7 days. The degree of contact sensitivity, measured 24 hr later, showed that prior inhalation inhibited the skin reaction to **toluene** diisocyanate but it did not change the skin reaction to chloro-dinitrobenzene in guinea pigs sensitized and challenged similarly with chloro-dinitrobenzene. The inhibition lasted up to 9 weeks. However, it did not occur in guinea pigs after intranasal instillation (instead of inhalation) and only occurred after oral dosage with **toluene** diisocyanate when the dose was relatively high. Treatment with cyclophosphamide before **toluene** diisocyanate inhalation reversed the inhibition of contact sensitivity, suggesting an involvement of suppressor cells. /**Toluene** diisocyanate/
[Doe J E et al; Int Arch Allergy Appl Immunol 68 (3): 275-9 (1982)]**PEER REVIEWED**

Human Toxicity Excerpts :

Radioallergosorbent testing was used to look for the presence of specific IgE antibody against a para-tolyl-monoisocyanate human serum albumin conjugate in sera from five groups of subjects. The first three groups consisted of individuals exposed to **toluene** diisocyanate who had been shown by bronchial provocation testing with levels of **toluene** diisocyanate below the threshold limit value of 0.02 ppm to have immediate asthmatic reactions, late asthmatic reactions or no resp changes at all. The two control groups consisted of atopic and non-atopic individuals who had no resp symptoms and no known exposure to **toluene** diisocyanate. Although radioallergosorbent showed high counts/min in some of the sera from patient with proven **toluene** diisocyanate induced resp disease, these levels were not significantly different from controls and appeared to reflect the presence in these sera of high levels of total IgE (greater than 100 u/ml). There is no evidence from this study for the presence of specific IgE antibody against a para-tolyl monoisocyanate human serum albumin conjugate in patients with **toluene** diisocyanate induced resp disease. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

... Patients with **toluene** diisocyanate induced asthma continue to be symptomatic for month and even yr after cessation of **toluene** diisocyanate exposure. ... It is thought that **toluene** diisocyanate may cause the airways to become hyperreactive to many agents such as smoke and other air pollutants. ... Some individuals susceptible to **toluene** diisocyanate induced asthma develop cross-reactivity to other diisocyanate. ... /**Toluene** diisocyanate/
[Amdur, M.O., J. Doull, C.D. Klaasen (eds). Casarett and Doull's Toxicology. 4th ed. New York, NY: Pergamon Press, 1991. 305]**PEER REVIEWED**

Human Toxicity Excerpts :

The sera of 20 blood donors, 70 factory workers, and 1 casualty patient were assayed for IgE which bound to a p-tolyl-isocyanate human serum albumin conjugate. 3 factory workers had abnormally high assay values in assoc with active **toluene** diisocyanate disease, as indicated by asthma or measurement showing chronic airway obstruction. One factory worker had an exceptionally high assay value without clinical evidence of **toluene** diisocyanate disease. Hapten inhibition studies indicated possible heterogeneity of the IgE detected by the assay. Clinical histories suggest that **toluene** diisocyanate disease can incl susceptibility to asthma triggered by events other than **toluene** diisocyanate exposure. /**Toluene** diisocyanate/

Medical Surveillance :

A SCREENING PROGRAM WAS UNDERTAKEN AT A RESEARCH & DEVELOPMENT FACILITY OF A LARGE **TOLUENE** DIISOCYANATE MANUFACTURING CORPORATION. THE PURPOSE WAS TO DETERMINE THE OCCURRENCE OF ANTIBODIES TO **TOLUENE** DIISOCYANATE IN SELECTED WORKER POPULATIONS. NO TOLYL-REACTIVE IMMUNOGLOBULIN-E ANTIBODIES WERE DETECTED IN SERA WHEN WORKERS WERE EXPOSED ONLY TO AMBIENT **TOLUENE** DIISOCYANATE CONCN. WORKERS HAD ACUTE EXPOSURES TO **TOLUENE** DIISOCYANATE AS A RESULT OF SPILLS OR SPLASHES. ANTIBODY RESPONSES DEVELOPED IN 3 OF 4 INDIVIDUALS WHOSE ACUTE EXPOSURES WERE ACCOMPANIED BY IMMEDIATE RESPIRATORY SYMPTOMATOLOGY & A DECREASED FORCED EXPIRATORY VOLUME. AN ANTIBODY RESPONSE DEVELOPED IN 1 OF 9 WORKERS & IMMEDIATE RESPIRATORY SYMPTOMS, BUT NO SPIROMETRIC CHANGES UPON ACUTE TDI EXPOSURE. ROUTINE SEROLOGIC SCREENING OF WORKERS FOR TOLYL-REACTIVE ANTIBODIES MAY BE OF VALUE IN CONFIRMING SUSPECTED ISOCYANATE EXPOSURE & IN PROVIDING AN EARLY WARNING OF DEVELOPING TDI HYPERSENSITIVITY. /**TOLUENE** DIISOCYANATE/
[KAROL MH; J OCCUP MED 23 (11): 741 (1981)]**PEER REVIEWED**

Environmental Fate/Exposure Summary :

Commercial **toluene** diisocyanate (TDI) typically contains 80% of 2,4-**toluene** diisocyanate. It may be released to the environment as fugitive emissions and from stack exhaust during the production, transport, and use of TDI in the manufacture of polyurethane foam products and coatings as well as from spills. Much of the enviromental fate and monitoring data does not distinguish between the isomers of **toluene** diisocyanate, however, since the types of reactions are similar, some of the data presented below is for the commercial TDI mixture. The reactivity of the 2,4-**toluene** diisocyanate with compounds containing active hydrogen, such as water, alcohols or acids is greater than with the 2,6- isomer; therefore, the percentage of 2,4-**toluene** diisocyanate in monitored TDI is generally much less than 80% in the commercial mixture. If spilled on wet land, TDI is rapidly degraded. If released into water, a crust forms around the liquid TDI and < 0.5% of the original material remains after 35 days. Low concentrations of TDI hydrolyze in the aqueous environment in approximately a day. In the atmosphere, TDI reacts with photochemically produced hydroxyl radicals (half-life 3.3 hr) and is also removed by dry deposition. Human exposure is primarily occupational via inhalation and dermal contact. (SRC)
PEER REVIEWED

Mechanism of Action :

Guinea pigs were exposed to 29 ppb of **toluene** diisocyanate (97.8% 2,4- and 2.2% 2,6-) vapors 5 hr/day for 20 consecutive days. Animals were killed 20 hr after the last exposure, and tracheal smooth muscle relaxation and contraction responses to agonists were determined. There was no difference in beta-adrenergic responsiveness between the exposed animals and controls. Significant differences in carbachol-produced contractability were observed. The dose-effect curve from carbachol-stimulated strips was shifted upward and to the left for **toluene** diisocyanate exposed animals. The maximal smooth muscle tension was also greater in **toluene** diisocyanate exposed animals. The observed incr in maximal tension and the shift of the dose-effect curve for **toluene** diisocyanate exposed animals suggest a direct effect of **toluene** diisocyanate on tracheal smooth muscle.

Non-Human Toxicity Excerpts :

Young adult guinea pigs received 2 open, epicutaneous induction applications (25 ul) of 8, 20 or 40% **toluene** diisocyanate in n-butyl ether on 2 separate areas. Five days later, animals were challenged with 0.0, 0.025, 0.05, 0.1, 0.2 and 0.4% TDI (25 ul/concn site). All challenge applications except the 0.0% soln elicited a positive response in 75-100% of the animals, and the severity of the skin reactions was dependent on the concn of the challenge and induction application. In another study using lower doses, animals received a total induction application (25 ul/each of 2 sites) of either 4 or 8% **toluene** diisocyanate. **Toluene** diisocyanate did not elicit a sensitization response at challenge concn up to 0.012% (total application of 3 ug) when a 4% induction application was used, while a challenge concn of 0.025% (total application of 6.25 ug) elicited a sensitization response in 63% of the animals. At the 8% induction application (total application of 4000 ug), all challenges, except the 0.0% indicated sensitization, and the intensities of the skin reactions were correlated with the challenge concn and the induction application. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

Toluene diisocyanate (TDI) sensitivity accompanied by nonspecific bronchial hyperresponsiveness occurs in approximately 5% of occupationally exposed workers. We report the case of a 32 yr old worker followed longitudinally after removal from isocyanate exposure. **Toluene** diisocyanate reactivity was lost 11 mo after removal from exposure and nonspecific bronchial hyperresponsiveness resolved after 17 mo. Bronchial reactivity to radishes (Raphanus sativus), which developed concurrently with **toluene** diisocyanate reactivity, was lost 2 yr later. Immunopharmacologic results show that the worker's initial decreased ability of lymphocytes to produce cyclic AMP returned to near normal after 2 yr. IgE antibodies to a human serum albumin tolyl monoisocyanate conjugate were still present at this time. /**Toluene** diisocyanate/

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Toluene** diisocyanate (TDI) is an irritant to skin, lungs, conjunctiva and the mucous membranes of the gastrointestinal tract. Exposure can result in chemical pneumonitis, bronchospasm, bronchitis, and pulmonary edema; it is one of the leading causes of occupational asthma. Neurologic symptoms may include euphoria, loss of coordination, loss of consciousness, memory loss, and depression.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Severe conjunctival irritation and lacrimation from liquid or high vapor concentrations is likely. Corneal edema may also occur. Lower concentrations may produce a burning or prickling sensation.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Burning or irritation of the nose and throat, cough, laryngitis, chest pain, and asthmatic syndrome (chemical bronchitis with severe bronchospasm), sensation of oppression or constriction of the chest, bronchitis, pulmonary edema, and cor pulmonale may occur.
- Occupational asthma, emphysema, decreased pulmonary function, and hypersensitization may occur from chronic exposure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute exposures may produce headache, insomnia, euphoria, ataxia, anxiety neurosis with depression, paranoid tendencies, or impotence.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Inhalation of vapor or aerosol may produce vomiting and abdominal pain. Epigastric and substernal pain may be secondary to the paroxysmal or persistent cough associated with inhalation.

HEMATOLOGIC

0.2.13.2 CHRONIC EXPOSURE

- Long-term effects may include blood cell damage and anemia.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Irritation and inflammation are common. TDI is corrosive. Skin sensitization and allergic eczema may occur.

REPRODUCTIVE HAZARDS

- At the time of this review, no data were available to assess the teratogenic potential of this agent.
- At the time of this review, no data were available to assess the potential effects of exposure to this agent during pregnancy or lactation.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- There is no data for evidence of carcinogenicity in humans; there is sufficient evidence in animals. It is rated as a 2B carcinogen by IARC (HSDB, 1998).

0.2.21.2 HUMAN OVERVIEW

- A 47 year old nonsmoking spray painter who had been exposed to **toluene** diisocyanate and 4,4-methylenediphenyl diisocyanate for 15 years developed an adenocarcinoma of the lung.
- A slight, but not significant, increase in rectal cancer and non- Hodgkin's lymphoma was found in workers in a polyurethane foam manufacturing plant.

0.2.21.3 ANIMAL OVERVIEW

- Rats and mice fed commercial grade **toluene** diisocyanate developed hemangiosarcomas in the liver, ovaries, and peritoneum; hepatocellular adenomas; pancreatic acinar cell adenomas; pancreatic islet cell adenomas; mammary gland tumors; and subcutaneous fibromas and fibrosarcomas.

GENOTOXICITY

- TDI induced mutations in S typhimurium and an increased incidence of sister chromatid exchanges occurred in Chinese hamster ovary cells. TDI did not induce chromosomal aberrations in Chinese hamster ovary cells.

Laboratory:

- Monitor respiratory function closely. Serum and urine toluenediamine levels should also be monitored.

Treatment Overview:

ORAL EXPOSURE

- Due to the irritant nature of this substance, emesis is not advised.
- GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
  1. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.
- ACTIVATED CHARCOAL/CATHARTIC: Administer charcoal slurry, aqueous or mixed with saline cathartic or sorbitol. The FDA suggests 240 mL of diluent/30 g of charcoal. Usual charcoal dose is 25 to 100 grams in adults and adolescents, 25 to 50 grams in children (1 to 12 years old), and 1 gram/kilogram in infants less than 1 year old.
  1. Routine use of cathartics is NOT recommended. If used, administer only ONE dose of cathartic. Administer one dose of a cathartic, mixed with charcoal or given separately. See "Treatment: Prevention of Absorption" in the main document.
- Monitor patient for respiratory distress. If a cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis and pneumonia.
- Allergic reaction - Sensitized individuals should be cautioned to avoid further exposure as serious allergic reactions may result.

- NOTE: See treatment of oral exposure in the main body of this document for complete information.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- The specific role of bronchodilators for treatment of severe bronchoconstriction has not been evaluated. Asthma from TDI can be induced in the absence of airway hyperresponsiveness; in these cases bronchodilator use may contribute little to modifying severity.
- NOTE: See treatment of inhalation exposure in the main body of this document for complete information.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.
- NOTE: See treatment of eye exposure in the main body of this document for complete information.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
- NOTE: See treatment of dermal exposure in the main body of this document for complete information.

[Rumack BH: POISINDEX(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001. Hall AH & Rumack BH (Eds):TOMES(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001.] **PEER REVIEWED**

Human Toxicity Excerpts :

The outcome of the resp symptoms, pulmonary function tests and bronchial hyper-responsiveness was studied in 47 workers with resp disease due to **toluene** diisocyanate (27 asthmatic and 20 non-asthmatic subjects) after about 2 yr from the first exam. The data suggest that stopping occupational exposure to **toluene** diisocyanate frequently did not produce an improvement of the **toluene** diisocyanate bronchial asthma, and persistence of the exposure causes a more rapid decline in the resp function. /**Toluene** diisocyanate/
[Paggiaro PL et al; Clin Allergy 14 (5): 463-9 (1984)]**PEER REVIEWED**

Human Toxicity Excerpts :

The biconcave shape of normal human erythrocytes was altered into cup-shaped cells by **toluene** diisocyanate. The extent of **toluene** diisocyanate induced shape change of erythrocytes was concn-dependent. The resultant modified red cells had a decr ability to pass through a microporous membrane and also an incr resistance to hemolysis. Isolated membranes obtained from **toluene** diisocyanate treated cells showed incr crosslinking of membrane proteins and phospholipids. /**Toluene** diisocyanate/
[Manno S; Tokyo Joshi Ika Daigaku Zasshi 54 (7): 581-94 (1984)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Allergic dermatitis was developed in mice by sensitization to **toluene** diisocyanate following which the mice were exposed to **toluene** diisocyanate vapor to see if a delayed type allergy plays a role in lung disorders caused by **toluene** diisocyanate. At a concn of 0.6 ppm, inhaled for 2 hr, allergic dermatitis did develop, but without noticeable pathological change in the resp organs. /**Toluene** diisocyanate/
[Ohsawa T; J Tokyo Women's Med Coll 53 (3): 237-46 (1983)]**PEER REVIEWED**

Medical Surveillance :

MEDICAL EVALUATIONS OF 15 WORKERS WERE MADE TO DETERMINE THE HEALTH EFFECTS OF EXPOSURE TO **TOLUENE** DIISOCYANATE PHOSGENE & **TOLUENE** DIISOCYANATE. THE FOLLOWING STEPS WERE RECOMMENDED: THE ENTIRE FACTORY POPULATION SHOULD BE SURVEYED PERIODICALLY FOR SYMPTOMS OF LOWER RESPIRATORY TRACT DISEASES & LUNG FUNCTION ABNORMALITIES THAT MAY BE CAUSED BY CHEMICAL EXPOSURE; **TOLUENE** DIISOCYANATE EXPOSURE SHOULD BE ENDED FOR SENSITIZED WORKERS OR FOR THOSE WITH EXCESSIVE DECLINE IN LUNG FUNCTION. /**TOLUENE** DIISOCYANATE/
[COSTELLO RJ, PETERS JM; HEALTH HAZARD EVALUATION DETERMINATION REPORT NO HE-78-31-623, OLIN CORPORATION, ASHTABULA, OHIO 44004; REPORT NIOSH-HE-78-31-623, ORDER NO PB80-195274 (1979)]**PEER REVIEWED**

Interactions :

2,4-**Toluene** diisocyanate exerted a nonspecific inhibitory effect on the beta-adrenergic adenylate cyclase system of frog erythrocyte membrane preparation stimulated by the beta-agonist isoproterenol in vitro. This inhibition was dose-dependent, ie, incr concn of **toluene** diisocyanate (TDI) produced progressively greater inhibition. The similarity in response between **toluene** diisocyanate and the isocyanates 1,6-diisocyanatohexane & diphenylmethane 4,4'-diisocyanate suggests that the isocyanate group plays a critical role in inhibiting the responsiveness of this system to beta-agonists.
[McKay T et al; Chest 80 (1, Suppl): 61-3 (1981)]**PEER REVIEWED**

Evidence for Carcinogenicity :

Evaluation: There is inadequate evidence for the carcinogenicity of **toluene** diisocyanates in humans. There is sufficient evidence for the carcinogenicity of **toluene** diisocyanates in experimental animals. Overall evaluation: **Toluene** diisocyanates are possibly carcinogenic to humans (Group 2B).
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. 71 876 (1999)]**PEER REVIEWED**

Absorption, Distribution & Excretion :

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concentrations ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concentration of tolyl group after 72 hr and persists at a nanomolar level even 2 weeks following the exposure. This is similar to the response previously reported by this group for radioactively labeled methyl isocyanate. The initial ratre of (14)C uptake is also a linear function of the concentration of **toluene** diisocyanate when expressed either as concentration (ppm) or as concentration multiplied by duration of exposure (ppm/hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm/hr. Finally the inclusion of the data on methyl

isocyanate indicates that the uptake into arterial blood is a function of exposure concentration, independent of isocyanate structure. /**Toluene** diisocyanate/
[Kennedy AL et al; Toxicol Appl Pharmacol 100 (2): 280-92 (1989)]**PEER REVIEWED**

Mechanism of Action :

Non-specific bronchial reactivity to histamine has been measured before specific occupational bronchial tests in 51 workers exposed to **toluene** diisocyanate. The results showed that histamine reactivity was an important, but not obligatory, factor in the development of occupational asthma, and that it appeared to be the result rather than the cause of occupational asthma, as it returned towards normal in workers removed from exposure. **Toluene** diisocyanate was shown to be acting as a specific cause of occupational asthma rather than a non-specific irritant at a concn up to 0.02 ppm. /**Toluene** diisocyanate/
[Burge PS; Eur J Respir Dis (Suppl) 123: 91-6 (1982)]**PEER REVIEWED**

TSCA Test Submissions :

The mutagenicity of **toluene** 2,4-diisocyanate was evaluated in Salmonella tester strains TA98, TA100, TA1535, TA1537 and TA1538 (Ames Test), both in the presence and absence of metabolic activation by Aroclor-induced rat liver S9 fraction. Based on preliminary toxicity determinations, **toluene** 2,4-diisocyanate, diluted in acetone, was tested at concentrations up to 300 ug/plate with metabolic activation and up to 8 ug/plate without metabolic activation using the plate incorporation technique. **Toluene** 2,4-diisocyanate did not cause a positive response in any tester strain with or without metabolic activation.
[Haskell Laboratory; Mutagenic Activity of Toluene 2,4-Diisocyanate in the Salmonella/Microsome Assay, (1976), EPA Document No. FYI-OTS-0484-0302, Fiche No. OTS0000302-0] **UNREVIEWED**

Environmental Biodegradation :

Toluene diisocyanates are expected to be hydrolyzed much more rapidly than they are attacked by microorganisms. The resulting **toluene** diamines are subject to a wide variety of biochemical transformations. /**Toluene** diisocyanates/
[ITC/USEPA; Information Review #231 (Draft) Toluene Diisocyanates p.19 (1981)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Groups of male and female rats and mice were exposed to 0.05 and 0.15 ppm of **toluene**-diisocyanate by inhalation for 6 hr/day, 5 days/week for approx 2 years. Type and incidence of tumors and the number of tumor-bearing animals of either species did not indicate any carcinogenic effect. Hematology, biochemistry, urinalysis, and cytogenicity did not reveal any untoward effect. Increased mortality (females only), reduced weight gain and signs of irritation in the upper and lower respiratory tract resulted from exposure to **toluene** diisocyante in the mouse study with the highest incidence in the 0.15 ppm exposure level. Male and female rats of the 0.15 ppm group gained less weight during the first 12 weeks of the study. Histopathological examination in the rat study has not been completed, but no effect in the respiratory tract or in any other tissue has yet been seen. /**Toluene** diisocyanate/
[Loeser E; Toxicol Lett 15 (1): 71-81 (1983)]**PEER REVIEWED**

Human Toxicity Excerpts :

Resp health of 277 **toluene** diisocyanate workers was studied prospectively. Peak and 8-hr TWA concn were determined in over 200 samples. Smoking had a significant effect on spirometric tests and lung volumes. After adjustment for smoking, the 74 men in the high **toluene** diisocyanate exposure group had significantly larger declines in forced expiratory vol than the 149 men in the low exposure category. /**Toluene** diisocyanate/
[Diem JE et al; Am Rev Respir Dis 126 (3): 420-8 (1982)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Two strains of guinea pigs were parenterally immunized with well-characterized diisocyanate-protein conjugates. Hapten-specific IgE antibodies were detected in the sera of English short-hair strain guinea pigs immunized with **toluene** diisocyanate-human serum albumin when the serum was analyzed by the 168 hr passive cutaneous anaphylaxis technique followed by iv challenge with a conjugate coupled to an unrelated carrier protein, transferrin. IgG1 antibodies and precipitating antibodies were demonstrated in Hartley strain guinea pigs immunized with the **toluene** diisocyanate-human serum albumin conjugate. It became apparent that immune responses of guinea pigs immunized with protein conjugates of bifunctional isocyanates were heterogeneous and involved multiple specificities for hapten, carrier protein, and new antigenic determinants. It was postulated that the complex nature of the immune response generated by diisocyanate cmpd in the guinea pig may also serve as an appropriate model of isocyanate-induced human sensitivity reactions, which are known to involve diverse immunologic and nonimmunologic mechanisms. /**Toluene** diisocyanate/

Human Toxicity Excerpts :

Several studies on the prognosis of isocyanate induced asthma show that a significant proportion of patients continue to experience asthmatic symptoms and nonspecific bronchial hyperresponsiveness after cessation of work, and that further exposure to isocyanates in sensitized subjects leads almost invariably to persistence of respiratory symptoms and of bronchial hyperresponsiveness and the deterioration of airway function. Specific bronchial reactivity to isocyanates may change after cessation of work; however, some subjects continue to be sensitive to **toluene** diisocyanate several months after cessation of work. The determination of an unfavorable prognosis for asthma seem to be the same as those for other types of occupational asthma due to low molecular weight compounds (ie red cedar asthma); long duration of exposure before the onset of asthma, long duration of symptoms before diagnosis, airway obstruction, and dual airway response after specific challenge tests. Also, single acute exposure to high levels of TDI in the workplace (spills) can result in persistent nonspecific bronchial hyperresponsiveness. Potential mechanisms of persistence of symptoms and of nonspecific bronchial hyperresponsiveness may be chronic inflammation, bronchial smooth muscle alteration, autonomic nervous system disregulation. /**Toluene** diisocyanate/
[Paggiaro PL et al; Bull Eur Physiophol Respir 23 (6): 565-9 (1987)]**PEER REVIEWED**

Non-Human Toxicity Excerpts :

Twenty-seven chemicals (including **toluene** 2,4-diisocyanate) previously tested in rodent carcinogenicity assays were tested for induction of chromosomal aberrations and sister chromatid exchanges in Chinese hamster ovary cells as part of a larger analysis of the correlation between results of in vitro genetic toxicity assays and carcinogenicity bioassays. Chemicals were tested up to toxic doses with and without exogenous metabolic activation. **Toluene** 2,4-diisocyanate at 300-1000 ug/ml did not induce chromosomal aberrations either with or without S9. Results from sister chromatid exchange assays were equivocal because, although no evidence for induction of sister chromatid exchanges was seen in tests conducted with S9, 2 of 3 trials performed in the absence of S9 and with delayed harvest showed a

significant elevation in the incidence of sister chromatid exchanges. In one trial, doses of 300-500 ug/ml resulted in a slight but significant rise in the number of sister chromatid exchanges per cell, but this response did not increase with dose; in the other, a significant dose related increase in the frequency of sister chromatid exchanges was observed within a range of 250-400 ug/ml.

Artificial Pollution Sources :

2,4-**Toluene** diisocyanate may be released to the environment, primarily as stack and fugitive emissions into air during its commercial production, handling, and processing prior to polyurethane foam production(1). It may also be released during the manufacture of polyurethane foam products and coatings, from sprays, insulation materials, and polyurethane foam coated fabrics(1). About 0.005% of the **toluene** diisocyanate (TDI) used in flexible foam slabstock plants is released in vent stack exhaust and this contains < 50% of the 2,4-isomer(2). Large quantities of TDI are transported by rail, road, and sea and there is a possibility of spills during loading or unloading(2).

[ROTHE A; BERUFSDERMATOSEN 24 (1): 7-24 (1976)]**PEER REVIEWED**

Mechanism of Action :

Exposure of workers to isocyanates may result in irritation and/or sensitization of the resp tract. An immunologic mechanism for sensitization has been presented. This investigation explored whether, as a possible mechanism for the irritation reaction, the toxic resp effect of isocyanates might be due to their ability to inhibit cholinesterase. Molar ratios of 50:1 or greater were required for 50% inhibition of purified human serum cholinesterase by 2,4-**toluene** diisocyanate. When whole human plasma was the source of cholinesterase, the molar concn of 2,4-**toluene** diisocyanate needed to effect 50% enzyme inhibition suggested affinity labeling by this reagent.
[Brown WE et al; Toxicol Appl Pharmacol 63 (1): 45-52 (1982)]**PEER REVIEWED**

Human Toxicity Excerpts :

In 37 polyurethane workers with isocyanate asthma, exam carried out 40 mo after exposure had ceased showed that asthmatic symptoms had disappeared in 32 workers but that chronic bronchitis had developed in six. The progressive impairment of ventilatory function was evaluated by measuring the decr in forced vital capacity and forced expiratory vol after exposure had ceased. Mean annual decr of 86.3 and 67.7 ml, respectively, were observed. **Toluene** diisocyanate induces chronic and irreversible lung damage even after exposure is discontinued, and impairment of forced vital capacity is greater than that of forced expiratory volume. /**Toluene** diisocyanate/

Volatilization from Water/Soil :

The vapor pressure of 2,4-**toluene** diisocyanate is 0.01 torr at 20 deg C(1) and, therefore, spilled TDI will not readily volatilize from soil and surfaces(SRC).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans, Some Chemicals used in Plastics and Elastomers 39: 287-323 (1985)]**PEER REVIEWED**

Environmental Abiotic Degradation :

Gas phase loss of TDI was originally thought to be due to reaction of TDI with water vapor(2). One early work showed that the percent disappearance of TDI in air depended almost solely on the water vapor concentration, increasing 3.2% per unit increase in absolute humidity (g water/kg dry air), so that at 15 g water/kg dry air, a 50% reduction in TDI was obtained(2). These reductions were obtained after 8 sec and did not differ appreciably after 75 sec(2). The reaction product of 2,4-**toluene** diisocyanate vapor with limited quantities of moisture was reported to be 3,3'-diisocyanto-4,4'-dimethylcarbanilide(1). Other work contradicted these earlier findings and a program was instituted to study the gas-phase reactions between TDI and water using a room sized environmental chamber(4). They found that over a relative humidity range of 7-70%, the loss rate of TDI was independent of humidity and no toluenediamine or TDI-urea products could be detected(4). In addition deposition onto the chamber walls was an important removal process(4). Subsequent experiments were performed in the environmental chamber to assess the importance of photolysis, reaction with free radicals, and adsorption onto particulate matter as atmospheric removal processes(3). The loss rate of TDI in irradiated clean air was first order with a half-life of 3.3 hr(3). By using a free radical scavenger, it was shown that free-radicals and not photolysis was responsible for the removal. The half-life is consistent with the reaction with photochemically generated hydroxyl radicals(3). The addition of an urban surrogate hydrocarbon mixture (polluted urban air) or ammonium sulfate particulate matter, a major component of atmospheric aerosols, did not significantly alter removal rates(3). Because the concentration of hydroxyl radicals generally increases in polluted air, shorter half-lives are expected(SRC).

Absorption, Distribution & Excretion :

The absorption of gases in the respiratory tract is discussed. Formulas are presented for calculating saturation vapor concentrations and diffusion coefficients of gas absorption by the respiratory tract. Values are listed for 51 gases and vapors. Examples of the behavior of inhaled vapor and gaseous contaminants are ... **toluene**-2,4-diisocyanate. Foreign gases contaminating inhaled air are absorbed in the respiratory tract by diffusion of the gas molecules to the surface of the airways. No gas can penetrate beyond the lungs or enter the alveolar region if contaminant molecules are eliminated. Elimination at the wall depends on the solubility of the gas molecules or on chemical fixation. In high concentrations, some gases can saturate the surfaces of the dead space airways. This action can stop diffusion, and penetration of the alveoli then takes place.

Non-Human Toxicity Excerpts :

Lesions occurring in the resp tract of mice after exposure to 10 sensory irritants, at a concn which elicited a resp rate decr of 50%, were compared with respect to type and severity. The RD50 of 2,4-**toluene** diisocyanate was 0.4 ppm. After exposure of mice for 6 hr/day for 5 days, the resp tract was examined for histopathological changes. All irritants produced lesions in the nasal cavity with a distinct anterior-posterior severity gradient.
[Buckley LA et al; Toxicol Appl Pharmacol 74 (3): 417-29 (1984)]**PEER REVIEWED**

Human Toxicity Excerpts :

A 46 year old man who had worked in a paint processing plant for over 29 years was admitted to the hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonities due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against TDT-HSA and MDI-HSA, precipitating antibody against TDI-HSA, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coomhbs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate-related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggest the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.

Human Toxicity Excerpts :

Clinical signs of isocyanate exposure involved mucosal irritation of the respiratory and gastrointestinal tracts. Conjunctival irritation, skin inflammation (erythema, pain, vesiculation),

and gastrointestinal disturbances (nausea, vomiting, abdominal pain) occur soon after exposure. Pulmonary symptoms include cough, burning, substernal pain, dyspnea, choking sensation, sputum production, and hoarseness. Prominent bronchospasm (eg, wheezing, rhonchi, dyspnea, cough) may be present. Neurologic symptoms include headache, insomnia, euphoria, ataxia, anxiety neurosis, depression, and paranoia which may persist for several weeks. Persistent memory deficits, personality changes, irritability, and depression have been reported after severe exposures to **toluene** diisocyanate. Lacrimation, photophobia, profuse lid edema, and superficial corneal abrasions were the most common ophthalmologic effects at Bhopal. No case of blindness or irreversible ocular damage was noted on follow-up examination. /Isocyanates/

Human Toxicity Excerpts :

Strong mucous membrane irritation causes eye, pulmonary, and gastrointestinal tract symptoms. These compounds are potent pulmonary sensitizers which cause bronchospasm, even in patients without prior airway hyperreactivity. Diisocyanate compounds act either as inducers of nonspecific bronchial hyperreactivity or as direct pharmacologic agonists. Isocyanates apparently have the potential to sensitize certain segments of the population. Elevated humoral antibodies (ie, specific IgE antibodies to the p-tolyl determinant but not the diisocyanate conjugate) were detected in sensitized workers, but cell-mediated immunity also may produce hypersensitivity reactions. In the absence of renewed exposure, radioallergosorbent titers may not distinguish sensitive from nonsensitized workers. At high doses, **toluene** diisocyanate may act directly on bronchial mucosa by interfering with cholinergic and adrenergic mechanisms. /Isocyanates/

Sampling Procedures :

A passive dosimeter for monitoring occupational exposure to both 2,6- and 2,4-**toluene** diisocyanate (TDI) was developed. The device is constructed from a 37 mm aerosol cassette. The collection medium used in the dosimeter is 0.5% sulfuric acid. Membranes of both the permeation and diffusion types were evaluated for use in the dosimeter. Microporous teflon diffusion membranes exhibited superior performance in terms of surface effects (mass transfer coefficient <0.006 ug/ppb/hr) and residual TDI (not detected) and were chosen for use. Collected TDI is determined as toluenediamine by either colorimetry using a modification of the Marcali technique or fluorometry using fluorescamine reagent. The manufacturer claims an accuracy of + or - 15%. A significant dependence on wind speed was minimized by use of a

second microporous membrane as a wind screen. The mass transfer rate of TDI was found to be approximately 0.0152 ug/ppb/hr and was equivalent for the 2,4- and 2,6- isomers of TDI.

Environmental Fate :

TERRESTRIAL FATE: Ten days after a spill of 13 tons of **toluene** diisocyanate (TDI) onto swampy, wet forest soil, TDI and toluenediamines were found in the soil(1,2). The TDI solidified and the area was covered with sand. The soil concn of TDI and toluenediamine combined declined from the parts per thousand to parts per million range between 10 days and 12 wk after the spill(2). No TDI was detected in a connecting brook 10 days after the spill(2). After 6 years, only TDI-derived polyureas were found at the site(1). In a simulated spill, 5 kg of TDI in a container was covered with 50 kg of sand and 5 kg of water at ambient temperatures and samples taken from the top and bottom of the sand pile. After 24 hr, 5.5% of the TDI remained unreacted and after 8 days 3.5% remained(2). The reaction product was largely polyureas(2).

Non-Human Toxicity Excerpts :

A number of industrial chemicals induce hypersensitivity responses in employees. 2,4-**Toluene** diisocynate (TDI) can cause pulmonary sensitization and allergic skin reactions. Since many commercial materials contain TDI, a study was designed to determine the concentration dependent elicitation of dermal sensitization in guinea pigs treated with TDI. Young adult guinea pigs received 2 open, epicutaneous induction applications (25 ul) of 8, 20 or 40% TDI in n-butyl ether on 2 separate areas. Five days later, animals were challenged with 0.0, 0.025, 0.05, 0.1, 0.2 and 0.4% TDI (25 ul per concentration site). All challange applications except the 0.0% solution elicited a positive response in 75-100% of the animals, and the severity of the skin reactions was dependent on the concentrations of the challenge and induction application. In another study using lower doses, animals received a total induction application (25 ul per each of 2 sites) of either 4 or 8% TDI and were challenged with 0.0, 0.006, 0.012, 0.025, 0.05 and 0.1% of TDI (25 ul per site). TDI did not elicit a sensitization response at challenge concentrations up to 0.012% (total application of 3 ug) when a 4% induction application was used, while a challenge concentration of 0.025% (total application of 6.25 ug) elicited a sensitization response in 63% of the animals. At the 8% induction application (total application of 4000 ug), all challenges, except the 0.0% indicated sensitization, and the intensities of the skin reactions were correlated with the challenge concentrations and the induction application. TDI produced sensitization at dilute induction concentrations and the severity of the dermal response was correlated with the concentration used at induction and challenge. No observed effect levels were determined below which the challenge concentration did not elicit a dermal hypersensitivity reaction. When 4% TDI was applied at induction, no observed effect was seen with a dermal challenge application of 3 ug whereas an effect was seen with 6.25 ug (in 35 ul) when n-butyl ether was the solvent.

Non-Human Toxicity Excerpts:

The effect of exposure to **toluene** diisocyanate vapor on pulmonary performance was studied in guinea pigs. Female English smooth haired guinea pigs were exposed to 1.4 ppm **toluene** diisocyanate vapor or air for 3 hours per day for 4 days, or to 0.02 ppm **toluene** diisocyanate for 6 hours per day for 70 days. Pulmonary performance was evaluated by the ventilatory response of the animals to 10% carbon dioxide. Serum antibodies to **toluene** diisocyanate were measured on days 22 and 50 and **toluene** diisocyanate pulmonary hypersensitivity was measured on days 37 and 38. Lung tissue histopathology was evaluated in all animals on day 50 following **toluene** diisocyanate exposure. Pulmonary response to 10% carbon dioxide diminished by 30 to 50% following **toluene** diisocyanate exposures at 1.4 ppm up to day 14. The ventilatory response showed recovery during the next 5 weeks. In contrast, animals exposed to 0.02 ppm **toluene** diisocyanate daily for 70 days showed no change in ventilatory response, nor did control animals that were not exposed to **toluene** diisocyanate. Antibodies were detected on day 22 and pulmonary hyprsensitivity to **toluene** diisocyanate was found in all animals exposed to 1.4 ppm **toluene** diisocyanate. No antibodies to **toluene** diisocyanate nor pulmonary hypersensitivity were detected in animals exposed to 0.02 ppm **toluene** diisocyanate or in control animals. Lung tissue on day 50 in the 1.4 ppm **toluene** diisocyanate exposed animals showed multifocal subchronic interstitial inflammation, localized pleural thickening, and peripheral lymphoid hyperplasia. No apparent abnormalities were observed in lung tissue of the 0.02 ppm exposed group. Exposure to 1.4 or 0.02 ppm **toluene** diisocyanate resulted in measurable and no apparent pulmonary toxicity in guinea pigs, respectively. The 10 percent carbon dioxide challenge provide several advantages for measuring pulmonary function. [Wang KL et al; J Toxicol Environ Health 15 (1): 137-48 (1985)]**PEER REVIEWED**

Non-Human Toxicity Excerpts:

Exposing guinea pigs to **toluene** diisocyanate causes an acute increase in airway responsiveness to inhaled acetylcholine. The mechanism of this increase in airway responsiveness is unknown. Capsaicin-sensitive afferent nerves and the tachykinins they release upon activation are important in controlling bronchomotor tone in guinea pigs. To determine whether tachykinins are important in **toluene** diisocyanate induced airway hyperresponsiveness, the effects of tachykinin depletion were studied using capsaicin, and competitive tachykinin antagonism, using (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P, on **toluene** diisocyanate induced airway hyperresponsiveness. In 9 of 9 untreated animals, **toluene** diisocyanate exposure caused a large and significant increase in airway responsiveness to acetylcholine. The mean concentration of acetylcholine required to decrease specific airway conductance by 50% below baseline (the PD50) was 1.51% before **toluene** diisocyanate exposure and 0.17% after **toluene** diisocyanate exposure ($p < 0.0005$). Capsaicin treatment had no effect on the PD50 but prevented the **toluene** diisocyanate induced increase in airway responsiveness in 10 of 12 animals. (The PD50 was 1.03% before **toluene** diisocyanate and 1.27% after **toluene** diisocyanate exposure.) Treatment with the tachykinin antagonist (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P also abolished the **toluene** diisocyanate induced increase in airway responsiveness in all 5 animals treated. Although **toluene** diisocyanate exposure also caused airway edema, the effect of capsaicin treatment on **toluene** diisocyanate induced hyperresponsiveness did not result from prevention of airway edema. **Toluene** diisocyanate exposure caused a marked increase in tracheal extravasation of intravenously administered Evans blue dye that was not prevented by capsaicin treatment.

Metabolism/Metabolites:

It has been previously shown that tachykinin depletion or antagonism prevented the increase in airway responsiveness to inhaled acetylcholine caused by exposure to **toluene** diisocyanate in awake guinea pigs. To insure that the effects of tachykinins were not limited to the extrathoracic airways and were not dependent on effects of **toluene** diisocyanate on baseline airway caliber, airway responsiveness to acetylcholine inhaled through tracheostomy in anesthetized and ventilated guinea pigs that were exposed to **toluene** diisocyanate or air after treatment with the tachykinin antagonist spantide, the tachykinin metabolism inhibitor phosphoramidon, or the vehicles for each drug were determined. When these drugs were administered before and during **toluene** diisocyanate exposure, spantide significantly inhibited the **toluene** diisocyanate induced increase in acetylcholine responsiveness and phosphoramidon significantly potentiated this effect, whereas neither drug altered acetylcholine responsiveness in air exposed animals. To determine whether tachykinins were exerting their effect primarily during **toluene** diisocyanate exposure or during the subsequent acetylcholine challenge, the effect of each drug on acetylcholine responsiveness was also examined when the drugs were given after **toluene** diisocyanate exposure. At that time, spantide did not inhibit **toluene** diisocyanate induced acetylcholine hyperresponsiveness and phosphoramidon did not potentiate it. Neither drug nor **toluene** diisocyanate increased pulmonary resistance measured through a tracheostomy in these anesthetized and ventilated animals. These results suggest that the **toluene** diisocyanate induced increase in acetylcholine responsiveness is mediated by release of tachykinins into the intrathoracic airways during exposure to **toluene** diisocyanate.

Mechanism of Action:

The effects of **toluene** diisocyanate on T-cell subpopulations and circulating lymphocytes in ten persons (five males)): 19 to 50 yr old, with **toluene** diisocyanate induced occupational asthma were examined. Five subjects revealed early and late asthmatic reactions to **toluene** diisocyanate (dual responders) and five revealed late asthmatic reactions (late responders). Subjects underwent inhalation challenge with 0.005 to 0.015 ppm **toluene** diisocyanate or filtered air for 10 to 30 min on two occasions. One second forced expiratory volumes were measured before and at periodic intervals between 30 min and 24 hr after challenge. Venous blood samples were drawn 30 min and 8, 24, 48, and 72 hr after **toluene** diisocyanate. Total and differential leukocyte counts and T-cell subpopulations were determined. The five dual responders demonstrated forced expiratory volume in 1 sec decreased indicative of early and late asthmatic reactions and the five late responders demonstrated forced expiratory volume in 1 second decr indicative of a late asthmatic reaction. **Toluene** diisocyanate challenge did not affect the number of circulating erythrocytes and leukocytes. The percentage of eosinophils was significantly increased 24 hr after challenge and sustained for up to 48 hr. The percentages of neutrophils, lymphocytes, and monocytes were not altered by **toluene** diisocyanate. Among the T-lymphocyte subpopulation, the proportion of CD8(+) lymphocytes was significantly increased 8 hr after **toluene** diisocyanate challenge. The increase was more pronounced in the lat responders. An additional increase in CD8(+) lymphocytes occurred 48 hr post exposure in seven subjects but was unrelated to responder type. The number of CD4(+) cells did not change. This resulted in a decrease in the CD4(+)/CD8(+) ratio 8 and 48 hr after **toluene** diisocyanate challenge. It was concluded that **toluene** diisocyanate induced late asthmatic reactions are associated with an increase in the number of suppressor/cytotoxic lymphocytes and eosinophils in peripheral blood.

Non-Human Toxicity Excerpts:

Toluene diisocyanate is a causative agent in occupational asthma. Through an oral catheter **toluene** diisocyanate, 0.03 ul, dissolved in 0.02 ml olive oil, was superfused on the tracheobronchial mucosa of anaesthetized guinea pigs. **Toluene** diisocyanate induced plasma exudation into both airway tissue and lumen (peak effect: 5 hr; duration approximately 17 hr). Light microscopy examinations demonstrated that the epithelium was not disrupted by this process (and that microvessels are abundant just beneath the epithelium). At days 6 and 21 after exposure to **toluene** diisocyanate PAS-positive cells were increased, but no other histological alterations were found. Also, the occurrence of peptide containing nerve fibres was not altered by **toluene** diisocyanate. After **toluene** diisocyanate exposure the airway smooth muscle tone was elevated as examined in vitro at base-line and at conc response to carbachol. The largest incr in tone were recorded 21 days after exposure to **toluene** diisocyanate. The abnormally large tone was not associated with an increased thickness of the smooth muscle layer nor was it associated with reduced effects of either beta 2-agonist (terbutaline) or xanthine (theophylline) relaxants. It is concluded that **toluene** diisocyanate induced plasma exudation into guinea pig airways for 17 hr without disrupting the epithelial lining and without causing major changes in the airway peptidergic innervation. Both the airway tone, and the number of mucous cells, are increased for at least 3 wk after exposure to **toluene** diisocyanate.

Mechanism of Action:

Serum neutrophil chemotactic activity, which is associated with mast cell or basophil activation, was quantitated to determine if mast cell or basophil mediators are released during bronchoprovocation-inhalation challenge with subirritant levels of **toluene** diisocyanate. Four subjects with suspected **toluene** diisocyanate induced asthma and four mite-sensitive subjects with asthma who served as a comparison group were studied. neutrophil chemotactic activity was measured in a multiwell, microchemotaxis chamber. Blood samples were collected, and forced expiratory volume in 1 second measurements were performed before challenge and at regular intervals during the subsequent 24 hr. Three of four workers clinically sensitive to **toluene** diisocyanate reacted to a subirritant **toluene** diisocyanate exposure. There was no increase in neutrophil chemotactic activity during placebo challenges. neutrophil chemotactic activity increased in the three **toluene** diisocyanate sensitive workers during early and late asthmatic reactions in quantities proportional to the forced expiratory volume in 1 second decline. No increase in neutrophil chemotactic activity was found during **toluene** diisocyanate exposures in the **toluene** diisocyanate negative worker. Gel filtration analysis demonstrated the main neutrophil chemotactic activity fraction eluted with macromolecules of an estimated molecular weight greater than 440,000 daltons. This characteristic is compatible with neutrophil chemotactic factor of basophil or mast cell origin. The kinetics of neutrophil chemotactic activity release were similar in mite- and **toluene** diisocyanate induced asthmatic reactions. A high correlation ($r = 0.97$; $p = 0.0006$) was obtained between the percent decrease in forced expiratory volume in 1 second during early asthmatic reactions and percent increase in neutrophil chemotactic activity. These observations support the hypothesis that activation of mast cells or basophils is associated with **toluene** diisocyanate induced early and late asthmatic reaction.

Human Toxicity Excerpts:

The mechanism by which late asthmatic reactions are induced by **toluene** diisocyanate, a low molecular weight chemical that causes occupational asthma in exposed subjects, is unknown. An investigation was conducted to determine whether early and late asthmatic reactions induced by **toluene** diisocyanate are associated with changes in airway responsiveness to methacholine and airway inflammation as determined by bronchoalveolar lavage. Forced expiratory volume in 1 second was measured before and at regular intervals after exposure to **toluene** diisocyanate and dose-response curves to methacholine and bronchoalveolar lavage at 8 hr after **toluene** diisocyanate /were performed/ in a group of 6 subjects with late asthmatic reactions and in 6 subjects with only early asthmatic reactions. The same procedure was followed 2 hr after **toluene** diisocyanate in a group of 6 subjects with previously documented late asthmatic reactions and in a group of 6 subjects without any previously documented asthmatic reaction after **toluene** diisocyanate. In subjects with late asthmatic reactions, neutrophils were increased at both 2 hr and 8 hr and eosinophils and airway responsiveness were increased only at 8 hr. By contrast, neutrophils, eosinophils and airway responsiveness were not increased at 8 hr after **toluene** diisocyanate in subjectswith an early asthmatic reaction or at 2 hr after **toluene** diisocyanate in normal control subjects. These results suggest that late asthmatic reactions to **toluene** diisocyanate, and the associated increase in airway responsiveness may be caused by airway inflammation.

Human Toxicity Excerpts:

Six workers with occupational asthma due to **toluene** diisocyanate were studied. For each worker a detailed clinical and occupational history was taken, and lung function measurement and skin intradermal tests for common allergens were carried out. Methacholine inhalation challenge was performed before **toluene** diisocyanate inhalation, and 8 hr after **toluene** diisocyanate inhalation. Methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, but went into the asthmatic range after **toluene** diisocyanate inhalation. These cases provid evidence that asthma can be induced by **toluene** diisocyanate in the absence of airway hyperresponsiveness. They further demonstrate that an isolated negative methacholine inhalation test cannot be used to exclude sensitization to **toluene** diisocyanate. Screening and follow-up studies on workers exposed on **toluene** diisocyanate require serial measurements of airway responsiveness and of variable air-flow obstruction.

Metabolism/Metabolites:

Five men were exposed to **toluene** diisocyanate atmospheres for 7.5 hr. The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8 cu m stainless steel test chamber. The mean air concn of **toluene** diisocyanate was ca 40 ug/cu m, which corresponds to the TLV of Sweden. The inhaled doses of 2,4- and 2,6-**toluene** diisocyanate were ca 120 ug. **Toluene** diisocyanate in the test chamber air was determined by an HPLC method using the 9-(N-methylaminomethyl)-anthracene reagent and by a continuous monitoring filter-tape instrument. After hydrolysis of plasma and urine, the related amines, 2,4- and 2,6-toluenediamine 2,4-, and 2,6-TDA), were determined as pentafluoropropionic anhydride derivatives by capillary gas-chromatography using selected ion monitoring in the electron-impact mode. The urinary elimination of the toluenediamines showed a possible biphasic pattern, with rapid first phases for 2,4-toluenediamine (mean half-life for the concn in urine, 1.9 hr) and for 2,6-toluenediamine (mean half-life for the concn in urine, 1.6 hr). The cumulative amount of 2,4-toluenediamine excreted in urine within 28 hr ranged from 8% to 14% of the estimated dose of 2,4-**toluene** diisocyanate, and the cumulative amount of 2,6-toluenediamine in urine ranged from 14% to 18% of the 2,6-**toluene** diisocyanate dose. The average urinary level of 2,4-toluenediamine was 5 ug/l in the 6 to 8 hr sample (range 2.8-9.6 ug/l), and the corresponding value fo 2,6-toluenediamine was 8.6 ug/l (range, 5.6-16.6 ug/l). Biological monitoring of exposure to 2,4- and 2,6-**toluene** diisocyanate by analysis of 2,4- and 2,6-toluenediamine in urine is feasible.

Human Toxicity Excerpts:

To determine whether late asthmatic reactions and the associated increase in airway induced by **toluene** diisocyanate are linked to airway inflammation, inhibition by prednisone was investigated. Ten "sensitized" subjects were studied in 2 sets of experiments. In the first set, each subject was given no treatment and was studied before and for 8 hr after exposure to **toluene** diisocyanate. In the second set, 2 to 4 wk later, each subject was studied before treatment and then during treatment with prednisone (50 mg once a day for 3 days, orally), both before and after exposure to **toluene** diisocyanate. To assess late asthmatic reactions to **toluene** diisocyanate FEV1 /was measured/ immediately before and after exposure, then hourly for 8 hr. To assess changes in airway responsiveness, a /measurement was made of/ the provocation dose (mg) of methacholine causing a 20% decrease in FEV1 (PD20FEV1) before and 8 hr after exposure to **toluene** diisocyanate. When the subjects received no prednisione treatment, **toluene** diisocyanate caused late asthmatic reactions and increased airway responsiveness. By contrast, when the subjects received prednisone, **toluene** diisocyanate caused no late asthmatic reaction or increased airway responsiveness. Prednisone did not change baseline airway caliber or airway responsiveness. These results suggest that late asthmatic reactions and the associated increase in airway responsiveness induced by **toluene** diisocyanate in "sensitized" subjects may depend on the development of a steroid-responsive acute inflammatory reaction within the airways.

Human Toxicity Excerpts:

A worker developed **toluene** diisocyanate induced asthma in 1974. On reassessment, 11 yr after leaving the chemical plant where **toluene** diisocyanate was produced, he had no respiratory symptoms and normal bronchial reactivity in response to methacholine, and showed no reaction when challenged with a subirritant concn of **toluene** diisocyanate. He developed asthma within five months of returning to the workplace. Repeat challenge testing showed bronchial hyperreactivity to methacholine and to the specific sensitising agent, **toluene** diisocyanate. This clinical pattern could be due to underlying **toluene** diisocyanate sensitivity with resolution and reappearance of hyperresponsiveness to methacholine and **toluene** diisocyanate reactivity associated with workplace **toluene** diisocyanate exposure. Alternatively, this worker may have developed sensitisation to **toluene** diisocyanate anew.

Mechanism of Action:

Leukotriene B4 release from the lungs of sensitized subjects during asthmatic reactions induced by **toluene** diisocyanate was investigated. Three groups of **toluene** diisocyanate sensitized subjects were examined, one after no exposure to **toluene** diisocyanate, the second 8 hr after an exposure to **toluene** diisocyanate that caused an early asthmatic reaction, and the third 8 hr after an exposure to **toluene** diisocyanate that caused a late asthmatic reaction. Bronchoalveolar lavage fluid was analysed by reverse-phase HPLC and by specific radioimmunoassay. The mean concn of leukotriene B4 was higher (0.31 + or - 0.09 (standard error) ng/ml, range 0.15-0.51) in bronchoalveolar lavage fluid of sensitized subjects who developed a late asthmatic reaction than in bronchoalveolar lavage fluid of subjects who developed an early asthmatic reaction (0.05 + or - 0.04 ng/ml, range 0-0.224), and no leukotriene B4 was detectable in the control subjects. Bronchoalveolar lavage was also performed 8 hr after **toluene** diisocyanate exposure on four **toluene** diisocyanate sensitized late-dual reactors who were on steroid treatment. In this group of subjects no leukotriene B4 was detectable. These results suggest that leukotriene B4 may be involved in late asthmatic reactions induced by **toluene** diisocyanate.

Interactions:

The effects of methacholine inhalation on airway responsiveness in **toluene** diisocyanate induced asthma were studied in six workers with a history of sensitivity to **toluene** diisocyanate. Symptoms among subjects included shortness of breath, wheezing, cough, and chest tightness at work, during the evening, or at night. A detailed cllnical and occupational history was taken for each subject, and lung function measurement and skin intradermal tests for common allergens were conducted. Airway responsiveness to methacholine was assessed before subjects were exposed for 30 minutes to 0.02 part per million **toluene** diisocyanate in an exposure chamber. Eight hours after **toluene** diisocyanate inhalation, airway responsiveness to methacholine was again determined. Forced expiratory volume was the measure of airway responsiveness. Although methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, the challenge went into the asthmatic range after **toluene** diisocyanate inhalation. Airway responsiveness increased significantly 8 hours after **toluene** diisocyanate challenge in the subjects and was accompanied by a decrease in forced expiratory volume. The late asthmatic reaction began between 3 and 5 hours asthma can be induced by **toluene** diisocyanate in the absence of airway responsiveness.

Protective Equipment & Clothing:

Three commercial air-purifying respirators for protection against **toluene** diisocyanate vapors were evaluated. The Willson R-21 and Survivair, organic vapor cartridges, and the disposable, valveless 3M-8711 were the three respirators evaluated. Each respirator/cartridge was tested three times at 0.2 ppm **toluene** diisocyanate concn for 40 hr and once for 20 hr or more at concn greater than 1.5 ppm **toluene** diisocyanate. All cartridges/respirators had the capacity to provide the required protection against **toluene** diisocyanate vapors. Additional considerations in the respirator selection process included the training and experience of the respirator user, the enforcement of the respirator program, fit of the respirator, knowledge of **toluene** diisocyanate concn onsite, presence of other solvents or chemicals in the air which may adversely affect the capacity of the respirato for **toluene** diisocyanate, and the high odor threshold of **toluene** diisocyanate that makes it impossible for the user to receive advance warning of a leak.

Analytic Laboratory Methods:

A solvent free sampling method for airborne **toluene** diisocyanate was described. Air samples were collected on quartz fiber filters impregnated with 1-(2-methoxyphenyl)piperazine. **Toluene** diisocyanate in the samples reacted with 1-(2-methoxyphenyl)piperazine to form urea derivatives which after dissolution in methanol were analyzed by reversed or normal phase HPLC. When reversed phase HPLC was used, a C18 bonded phase column was utilized. A cyano amino bonded phase column was used with normal phase HPLC. An ultraviolet detector set at a wavelength 250 nanometers was also used. Detection limits for a 15 liter air sample based on a 5 mm peak height were 0.02 to 0.04 mg/cu m, corresponding to 0.5 to 1 nanograms of **toluene** diisocyanate injected. The method was used to sample laboratory generated **toluene** diisocyanate containing atmospheres over the relative humidity range 11 to 75% and temperature range 20 to 50 deg C. In the study of the effects of humidity, samples were also collected with gas bubblers and silica gel tubes for comparison purposes. **toluene** diisocyanate concn in the collected samples increased linearly with incr temperature. When the samples were collected on the 1-(2-methoxyphenyl)piperazine coated fibers the collected **toluene** diisocyanate concn were not affected by changes in relative humidity. Collection efficiency of the bubblers and silica gel tubes decr for humidities in excess of 45%. It was concluded that the 1-(2-methoxyphenyl)piperazine impregnated quartz fiber filter method for **toluene** diisocyanate sampling is convenient and efficient, and that collection efficiency does not appear to be affected by humidity.

Human Toxicity Excerpts:

An outbreak of occupational asthma due to **toluene** diisocyanate among industrial workers was described. Four employees at a velcro/like tape manufacturing factory in Taipei, Taiwan were seen in an outpatient clinic complaining of cough, shortness of breath, and wheezing. The symptoms became worse at night and improved after long holidays. The patients' job involved applying an adhesive to the tape. Thirty eight of 45 employees were interviewed by questionnaire and given pulmonary function tests. The pulmonary function tests were given during a workday, after a 10 day holiday, and 5 mo after control measures such as process isolation, improved ventilation, and substitution for **toluene** diisocyanate were instituted. Industrial hygiene sampling for **toluene** diisocyanate was conducted. Fourteen workers had symptoms of asthma or asthmatic bronchitis. The highest attack rate occurred in workers employed in the tape processing area where the adhesive was applied. Workers in the tape processing area also showed the greatest decr in 1 second forced expiratory volume and forced vital capacity over the workday. Mean **toluene** diisocyanate concn ranged from 0.012 to 0.047 ppm, the highest occurring in the tape processing area and the lowest in the weaving area. The prevalence of asthmatic symptoms was significantly correlated with **toluene** diisocyanate concn. The forced expiratory volume in 1 second and forced vital capacity values were significantly improved after the 10 day holiday and 5 mo after the control methods were instituted. No asthmatic symptoms were reported after 5 mo. It was concluded that **toluene** diisocyanate was responsible for the outbreak and improving the work environment was effective in reducing exposure to **toluene** diisocyanate.

Human Toxicity Excerpts:

The effect of cessation of exposure to **toluene** diisocyanate was studied in six patients with **toluene** diisocyanate induced asthma, proved by a positive inhalation challenge with **toluene** diisocyanate. Bronchial challenges with **toluene** diisocyanate and methacholine were performed, and lobar bronchial biopsies were taken at diagnosis and 6 mo later, after cessation of exposure. Biopsies from four nonasthmatic control subjects were also examined. At diagnosis, asthmatic subjects had thickened reticular basement membrane ($p < 0.05$) and increased numbers of mononuclear cells ($p < 0.05$) and eosinophils ($p < 0.05$) in the lamina propria when compared with control subjects. Electron microscopy showed degranulation of eosinophils and mast cells in asthmatics. Six months after cessation of exposure, the thickness of reticular basement membrane was significantly reduced compared with that at diagnosis ($p < 0.05$), and it decr to values similar to those of control biopsies. Inflammatory cell numbers in bronchial mucosa of asthmatic subjects did not change significantly 6 mo after removal from exposure, and degranulation of eosinophils and mast cells was still present. At the end of the study, airwa hyperresponsiveness to methacholine and/or sensitivity to **toluene** diisocyanate persisted in most of the asthmatic patients despite the cessation of exposure and the disappearance of asthmatic symptoms. In conclusion, in patients with occupational asthma induced by **toluene** diisocyanate, the avoidance of exposure to the sensitizing agent for 6 mo is able to reverse the reticular basement membrane thickening in the bronchial mucosa, but th inflammatory cell infiltrate, the specific sensitivity to **toluene** diisocyanate, and the nonspecific airway hyperreactivity may persist.

Human Toxicity Excerpts:

Among the painters handling polyurethane varnish in two furniture manufacturing factories with high **toluene** diisocyanate exposure (0.79 mg/cu m and 0.31 mg/cu m), 26.3% and 15% subjects, respectively displayed asthmatic symptoms, lung function loss, and an increment in mast cell degranulation percentage specific to **toluene** diisocyanate. Some cases of **toluene** diisocyanate linked contact dermatitis were also found among them, being elucidated by positive patch testing to **toluene** diisocyanate. However, the previous abnormalities could not be verified among the painters from another factory with **toluene** diisocyanate concn below the TLV of it (0.11 mg/cu m). It was concluded that both pulmonary hypersensitivity and contact sensitization to **toluene** diisocyanate had occurred in some of the painters included in this study, and that the immunologic effects of **toluene** diisocyanate was concn dependent.

Human Toxicity Excerpts:

Pulmonary function tests were done and compared to current and past potential exposure levels of **toluene** diisocyanate for 57 **toluene** diisocyanate manufacturing workers and 89 workers not exposed to **toluene** diisocyanate or other known respiratory hazards. The average **toluene** diisocyanate plant experience was 4.1 yr (standard deviation = 2.8). Routine industrial hygiene measurements have shown **toluene** diisocyanate exposure below a time-weighted average of 0.005 ppm and a short-term exposure level of 0.02 ppm. A certified industrial hygienist ranked department and job classification by level of potential exposure to **toluene** diisocyanate (none, low, moderate, and high). A questionnaire was administered to determine the prevalence of respiratory symptoms and smoking habits. Using backward regression analysis, cumulative pack-years of cigarette smoking and prevalence of lower respiratory symptoms were statistically significant predictors of a standardized forced expiratory volume at 1 second; however, **toluene** diisocyanate exposure, whether classified as current, highest career level, cumulative, or cumulative highest-to-date, was not associated with a decline in forced expiratory volume. Mechanism of Action:

Isocyanates are an important cause of occupational asthma. The mechanism of isocyanate induced asthma is still unknown. To determine whether **toluene** diisocyanate stimulates the 'efferent' function of peripheral endings of capsaicin-sensitive sensory nerves, we investigated the effect of **toluene** diisocyanate in the rat isolated urinary bladder, a preparation in which the action of capsaicin has been well characterized. **Toluene** diisocyanate (0.03 mM) produced a concn dependent contraction of the bladder strips. It maximal effect was about 50 % of the response to capsaicin (1 uM). Previous exposure of the strips to capsaicin followed by washing out produced complete unresponsiveness, both to the first exposure to **toluene** diisocyanate and to a second exposure of capsaicin. Further, the response to both **toluene** diisocyanate and capsaicin was completely prevented by extrinsic bladder denervation, achieved by bilateral removal of pelvic ganglia (72 hr before). Repeated exposure of the rat bladder to **toluene** diisocyanate reduced the capsaicin-evoked release of calcitonin gene-related peptide like immunoreactivity (CGRP-LI), taken as biochemical marker of activation of these sensory nerves. These experiments provide the first evidence that **toluene** diisocyanate activates directly or indirectly the efferent function of capsaicin-sensitive primary sensory nerves.

Non-Human Toxicity Excerpts:

The **toluene** diisocyanate induced delayed type hypersensitivity reaction in the ear of male mice was investigated and compared with the picryl chloride induced one. The results obtained were as follows: 1) When 1% **toluene** diisocyanate solution (20 ul/ear) as a challenging concentration was used for 7 week old ICR mice, distinct ear swelling was observed in every group sensitized with various concentrations (1-5%, 100 ul/animal) of **toluene** diisocyanate solution, and the swelling rate was the same or higher than that of picryl chloride induced delayed type hypersensitivity. 2) Five, 7 and 13 week old ICR mice showed a similar high response in TDI induced delayed type hypersensitivity, whereas the reactivity of 16 week old ICR mice was significantly lower than that of the above mentioned younger mice. 3) In both **toluene** diisocyanate and picryl chloride induced delayed type hypersensitivity reaction, ICR and BALB/c mice showed a similar high response, whereas the reactivity of ddY mice was significantly lower. The effects of dexamethasone and indomethacin were investigated with the **toluene** diisocyanate induced delayed type hypersensitivity model. The delayed type hypersensitivity reaction was suppressed significantly by both drugs, but the suppressive effects of dexamethasone were higher than that of indomethacin. All the above results indicate that the **toluene** diisocyanate induced delayed type hypersensitivity model in mice taking dye leakage as an index may be useful for evaluation of drugs for disorders derived from delayed type hypersensitivity reactions.

Non-Human Toxicity Excerpts:

The changes in airway responsiveness to increasing doses of an acetylcholine aerosol in anesthetized and ventilated guinea pigs 2, 6, or 24 hr after exposure to air or 1 ppm **toluene** diisocyanate were examined. Pulmonary resistance after the animals inhaled a buffered saline aerosol was used as baseline and was similar for air and groups. The concentration of acetylcholine calculated to cause a 200% increase in pulmonary resistance was significantly lower for animals studied at 2 hr (0.68%) or at 6 hr (0.77%), but not at 24 hr (2.39%), after than for air animals (3.07%). The increase in airway responsiveness in the exposed animals was associated with histologic changes in the trachea and intrapulmonary airways. Exposure to 2 ppm caused a patchy loss of cilia, shedding of epithelial cells into the airway lumen, and an influx of inflammatory cells into the trachea and other airways. In the lamina propria of the trachea, the concentration of extravascular polymorphonuclear leukocytes was 13 to 26-fold greater in animals studied 2 or 6 hr after exposure to 2 ppm **toluene** diisocyanate or at 2 hr after 1 ppm **toluene** diisocyanate than in animals exposed to air. The concentration of polymorphonuclear leukocytes in the epithelium was significantly increased only in animals examined 2 hr after 2 ppm **toluene** diisocyanate. Exposure to **toluene** diisocyanate also caused an influx of eosinophils into the tracheal mucosa. This influx occurred later and was more persistent than the influx of polymorphonuclear leukocytes. These results indicate that a single exposure to **toluene** diisocyanate can cause an increase in airway responsiveness that is associated with epithelial injury and acute airwayinflammation.

Human Toxicity Excerpts:

A study of individuals with occupational asthma induced by **toluene** diisocyanate was conducted. This was a followup of 35 patients, 25 males, with a history of isocyanate sensitization. They had 3 to 41 years' occupational exposure to isocyanate compounds. The subjects had been diagnosed with isocyanate asthma on the basis of their response to bronchial challenge with **toluene** diisocyanate. They were examined an average of 11 mo after diagnosis. They underwent bronchial challenge with **toluene** diisocyanate and methacholine. Forced expiratory volumes in 1 second were measured. Symptoms reported by the subjects were recorded. Twenty seven subjects were still asthmatic at followup as shown by a positive reaction to **toluene** diisocyanate challenge. They showed a deterioration in their forced expiratory volumes in 1 second and response to methacholine similar to that seen at diagnosis. Seventy seven percent of these subjects continued to have recurring attacks of dyspnea, wheezing, and cough which required medication. Twenty two of the asthma subjects had been removed from exposure. Subjects who recovered (did not react to **toluene** diisocyanate at the followup examination) showed an improvement in their forced expiratory volumes in 1 second and a reduced response to methacholine. At the time of diagnosis they tended to have an immediate or dual asthmatic reaction and were younger than the other subjects. The asthmatic subjects had dual or late reactions at diagnosis. It was concluded that respiratory symptoms, isocyanate sensitization, and airway hyperresponsiveness may persist for some time after exposure to **toluene** diisocyanate has ended.

Metabolism/Metabolites:

A technique for detectingurinary amine metabolites in rats exposed to **toluene** diisocyanate was evaluated. Skin tissue of rats was exposed to 40% **toluene**-2,4-diisocyanate solution in di-n-butyl-ether liquid. Rats were exposed daily for 3 hr on 4 consecutive days. Urine was collected in metabolic cages for 18 hr after the last exposure. Chromatographic techniques were used for nitrogen selective detection of nonderivatized amines. An autolinear temperature programmer was employed to analyze derivatized amine. The identity of the amine was confirmed by gas chromatography/mass spectrometry. A linear correlation was found between **toluene**-2,4-diamine added to urine and peak height. Peak height and recovery from the non hydrolyzed and from the hydrolyzed urine was about 85 and 70%, respectively. No free **toluene**-2,4-diamine or free **toluene**-2,4-diisocyanate was detected in the urine of rats exposed to **toluene**-2,4-diamine in hydrolyzed urine was 1.5 micrograms per milliliter. Gas chromatography/mass spectrometry confirmed the identity of the amine. /This/ highly sensitive technique tested is easy to apply and is effective for trace assays of amines.

Human Toxicity Excerpts:

Diisocyanate inhalation tests (maximal concn, 20 ppb; exposure time, 1-2 hr) were performed using **toluene** diisocyanate (TDI, n = 15) and diphenylmethane diisocyanate (MDI, n = 7) as well as methacholine challenges in 19 workers who had a clinical history of **toluene** diisocyanate/diphenylmethane diisocyanate induced asthma. Additionally volunteers were tested who had n previous contact with diisocyanates: 10 healthy individuals with a negative methacholine test and 14 patients with asthma and a positive methacholine test were exposed to **toluene** diisocyanate. In all, 1 of the normal volunteers and 3 of the patients with asthma unrelated to diisocyanates showed a positive airway reaction to **toluene** diisocyanate, and 13 of the 19 diisocyanate workers displayed a positive result in the **toluene** diisocyanate/diphenylmethane diisocyanate inhalation test; however, only 6 of these 13 individuals reacted to methacholine. Furthermore, 3 of the 6 patients with a negative **toluene** diisocyanate/diphenylmethane diisocyanate challenge test demonstrated a significant response to methacholine. It was concluded that bronchial hyperreactivity as evaluated by the methacholine challenge test is not closely related to isocyanate induced bronchoconstriction and, therefore, the metacholine challenge is only of limited diagnostic value in patients with suspected isocyanate induced asthma.

Mechanism of Action:

To determine whether early and/or late asthmatic responses induced by **toluene** diisocyanate are caused by a reflex mechanism involving stimulation of muscarinic receptors, we studied the effect of the muscarinic antagonist atropine on early and late airway response induced by **toluene** diisocyanate. A preliminary study was conducted in asthmatics to assess whether the selected dose of atropine provided adequate muscarinic blockade. On different days we measured the provocation dose (in mg) of carbachol causing a 15% decrease in forced expiratory volume in 1 second (PD15FEV1) without and with atropine premedication (0.008 or 0.012 mg/kg sc atropine 30 or 90 min before carbachol challenge test). 0.008 to 0.012 mg/kg sc atropine increased the PD15FEV1 carbachol by 6 to 10 fold, inducing a consistent and prolonged decrease in nonspecific bronchial hyperresponsiveness to cholinergic agent. 10 Subjects with a history of sensitization to **toluene** diisocyanate were then examined in 2 sets of experiments. In the first set of experiments, the subjects were studied before and after exposure to **toluene** diisocyanate (0.04 ppm; 30 min) after no treatment. In the second set of experiments, carried out 1 to 2 wk later, the same procedure was repeated after treatment with atropine (0.008 to 0.012 mg/kg atropine sulfate administered sc 30 min before **toluene** diisocyanate challenge, and then at 90 min intervals after **toluene** diisocyanate exposure); all patients showed symptoms of atropine effect (dryness of mouth, cycloplegia, increased heart rate).

Human Toxicity Excerpts:

An investigation of the persistence of isocyanate induced asthma in workers with negligible occupational exposure was carried out. Six asthmatic workers, proven to be **toluene** diisocyanate sensitive by inhalation challenge testing in a longitudinal study of respiratory health risks associated with polyurethane foam production, were examined. The subjects were followed for 5 yr during which they completed a respiratory symptom questionnaire annually. Pulmonary function and responsiveness to methacholine challenge were measured annually. **toluene** diisocyanate concn in their breathing zones were measured. After the original survey the six subjects were transferred to areas thought to have negligible **toluene** diisocyanate exposures. None of the subjects had respiratory or asthmatic complaints before they started work in polyurethane production. The respiratory symptoms of the subjects did not improve during the followup period. All six had bronchial hyperresponsiveness to methacholine that did not resolve over time. Three subjects demonstrated deficits in 1 second forced expiratory volume of greater than 15% on one of the testing days during the followup period. The need for less or additional asthma therapy of the subjects could not be predicted. The mean time weighted average **toluene** diisocyanate exposure experienced by the subjects was 0.64 ppb; less than 5% of the OSHA standard of 20 ppb. It was concluded that although the outcome of isocyanate induced asthma cannot be predicted, the asthmatic symptoms of these workers have persisted despite the negligible **toluene** diisocyanate exposures.

Mechanism of Action:

In order to determine whether treatment with ketotifen inhibits asthmatic reactions induced by **toluene** di-isocyanate, six sensitized subjects with previously demonstrated dual or late asthmatic reaction after inhalation challenge with **toluene** diisocyanate were studied. Ketotifen (1 mg bid, orally) or placebo was administered for 7 days to the examined subjects, according to a double-blind, cross-over, placebo controlled study design. When the subjects were treated with either ketotifen or placebo, forced expiratory volume in 1 second markedly decr after exposure to **toluene** diisocyanate. These results suggest that the anti-asthmatic agent ketotifen is not effective in **toluene** diisocyanate induced asthma and suggest that it should not be used in the prophylaxis of asthmatic reactions induced by **toluene** diisocyanate in sensitized subjects.

Mechanism of Action:

To determine the importance of airway inflammation for the development of late asthmatic reactions, we examined sensitized subjects during late asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. Late asthmatic reactions are associated with a transient increase of bronchial responsiveness and, at the same time, with an increase of neutrophils followed by eosinophils, and of leukotriene B4 and albumin in bronchoalveolar lavage fluid. Late asthmatic reactions, increased bronchial responsiveness, and increase of neutrophils, eosinophils, leukotriene B4, and albumin concn in bronchoalveolar lavage induced by exposure to **toluene** diisocyanate are all prevented by pretreatment with prednisone but not with the nonsteroidal anti-inflammatory agent indomethacin. Aerosolized steroids (beclomethasone and dexamethasone isonicotinate) completely inhibit late asthmatic reactions induced by **toluene** diisocyanate, whereas theophylline has a partial, and verapamil, ketotifen, and cromolyn have no protective effect. These results suggest that late asthmatic reactions induced by **toluene** diisocyanate may be caused by airway inflammation, and that anti-inflammatory steroids should be recommended in the prophylaxis of **toluene** diisocyanate asthma.

Mechanism of Action:

The influence of cyclophosphamide induced granulocyte depletion on **toluene** diisocyanate related changes in airway reactivity and pathology was assessed in guinea pigs. Twelve cyclophosphamide-treated and 12 control animals comprising each group were studied physiologically before and 2 hr after a single 10 min exposure to 3 ppm of **toluene** diisocyanate. Reactivity was determined in intact unanesthetized animals by measuring specific airway conductance before and during intravenous acetylcholine infusion. After testing, tracheal tissue for light microscopic examination was obtained from three hyperreactive guinea pigs in each exposed group and compared with tissue from treated and control animals (n = 3 each) that had not been **toluene** diisocyanate exposed. Cyclophosphamide treatment caused substantial decr in both circulating and airway granulocyte counts. However, the incidence and degree of bronchial hyperreactivity that occurred 2 hr post-**toluene** diisocyanate was similar in the untreated and treated groups. Results indicate that **toluene** diisocyanate induced bronchial hyperreactivity 1) occurs shortly after a brief high concn exposure and 2) appears independent of circulating or airway granulocyte counts.

Mechanism of Action:

A study of the occurrence of serum immunoglobulin-E and immunoglobulin-G antibodies in workers with isocyanate induced asthma was conducted. The study group consisted of 62 workers (58 males) being evaluated for occupational asthma. Thirty nine had been exposed to hexamethylene diisocyanate, 17 to diphenylmethane diisocyanate, and six to **toluene** diisocyanate. The subjects completed a respiratory and occupational questionnaire. Spirometric tests were administered. Skin prick tests were performed with 15 common inhalant allergens and **toluene** diisocyanate, hexamethylene diisocyanate, and diphenylmethane diisocyanate human serum albumin conjugates. Blood samples were collected and assayed for specific serum immunoglobulin-G and immunoglobulin-E antibodies to hexamethylene diisocyanate, diphenylmethan diisocyanate, and **toluene** diisocyanate. Specific inhalation challenges were conducted with hexamethylene diisocyanate, diphenylmethane diisocyanate, and **toluene** diisocyanate. Specific inhalation challenge with **toluene** diisocyanate, hexamethylene diisocyanate, or diphenylmethane diisocyanate induced significant bronchoconstriction in half of the subjects, late reactions being the most common. Twenty subjects had significantly elevated immunoglobulin-G concn and nine had significantly elevated immunoglobulin-G plus immunoglobulin-E concn. Six of 12 subjects with elevated immunoglobulin-E and immunoglobulin-G antibodies had positive skin prick tests for hexamethylene diisocyanate and one was sensitized to diphenylmethane diisocyanate. It was concluded that an association between isocyanate specific antibodies and the results of specific inhalation challenge tests has been established. This suggests that isocyanate induced asthma may involve an immunological mechanism.

Mechanism of Action:

To investigate the role of pharmacological mechanisms in **toluene** diisocyanate induced occupational asthma, the effects of **toluene** diisocyanate on rat trachea ring and lung parenchymal strip were studied in vitro. The most prominent effect observed was a stimulation of metacholine induced contraction of the tracheal ring by 1M **toluene** diisocyanate (added in dimethyl sulfoxide). The results were less pronounced when **toluene** diisocyanate was added from a stock solution prepared in water, which is possibly due to copolymerisation. It is concluded that the pharmacological effect of **toluene** diisocyanate may result from an autonomic imbalance between cholinergic and B-adrenergic neural control.

Mechanism of Action:

Intravenously administered endotoxin inhibits the polymorphonuclear leukocyte dependent airway edema produced in guinea pigs exposed to **toluene** diisocyanate. Tumor necrosis factor is produced in vivo by peripheral blood monocytes and tissue macrophages stimulated with endotoxin and has been shown to activate polymorphonuclear leukocyte's and vascular endothelial cells. To determine whether the inhibition of airway edema is mediated by tumor necrosis factor, guinea pigs were treated with intravenous saline or 75,000 U/kg recombinant human tumor necrosis factor 1.5 hr before exposure to air or 3 ppm **toluene** diisocyanate for 1 hr. Animals were then injected intravenously with 50 mg/kg Evans blue dye as a marker of protein extravasation. Saline-treated animals exposed to **toluene** diisocyanate had a significant increase in tracheal Evans blue dye extravasation (85 + or - 6.5 ug dye/g trachea, mean + or - standard error) compared with saline-treated animals exposed to air (31.3 + or - 2.5, $P < 0.001$). The tracheal extravasation of Evans blue dye was significantly inhibited ($P < 0.05$) in **toluene** diisocyanate exposed animals treated with tumor necrosis factor (64.7 + or - 7.5). Neither heat-inactivated tumor necrosis factor (104.9 + or - 9.5) nor tumor necrosis factor neutralized with a monoclonal antibody against tumor necrosis factor (99.7 + or - 17.9) inhibited **toluene** diisocyanate induced airway edema. In addition, treatment with 15,000 U/kg (99.9 + or - 21.3) or 150,000 U/kg (103.2 + or - 17.6) interleukin 1, a monokine also produced in response to endotoxin, did not prevent airway edema. These results suggest that tumor necrosis factor released in response to endotoxin mediates endotoxin's inhibition of a polymorphonuclear leukocyte dependent airway edema.

Mechanism of Action:

Light and electron microscopic structure of lobar bronchial biopsies were examined of nine subjects with occupational asthma induced by **toluene** diisocyanate and of four control nonasthmatic subjects who had never been exposed to **toluene** diisocyanate. Inflammatory cell numbers were separately assessed in the intact epithelium, in the more superficial layer of the submucosa, and in the total submucosa. Asthmatic subjects had an increased number of inflammatory cells in the airway mucosa compared with control subjects. Eosinophils were significantly increased in all compartments, CD45-positive cells were significantly increased in the epithelium and in the more superficial layer of the submucosa, and mast cells were significantly increased only in epithelium. By electron microscopy eosinophils and mast cells appeare degranulated only in asthmatic patients. In the areas of epithelium that appeared intact by light microscopy, electron microscopy showed that, although the intercellular spaces between columnar cells were similar in asthmatic and control groups, the intercellular spaces between basal cells were significantly wider in patients with asthma. Patients with **toluene** diisocyanate induced asthma also had a thicker subepithelial reticular layer, where immunohistochemistry showed the presence of collagen III. In conclusion, in patients with asthma induced by **toluene** diisocyanate, the airway mucosa shows pathologic features, such as inflammatory cell infiltrate and thickening of subepithelial collagen, similar to those described in atopic asthma.

Probable Routes of Human Exposure:

In a Finnish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(1). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(1). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4-isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(1). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(1). TDI levels of 1.3-2.8 ppb were detected in air inside a Swedish factory manufacturing polyurethanes(2).

Analytic Laboratory Methods:

A passive monitor for **toluene** diisocyanate which utilizes microporous Teflon diffusion membranes and a 0.5% sulfuric acid absorbing medium was evaluated. The collection rate of **toluene** diisocyanate is proportional to exposure dose from 10 to at least 300 ppb.hr, and response is equivalent for 2,4- and 2,6-**toluene** diisocyanate. Collection rate is independent of humidity and normal atmospheric pressure variations, while temperature causes a decrease of 1.0% per deg C. Negative interference caused by ambient nitrogen dioxide is eliminated by addition of sulfamic acid to the collecting medium. N-Ethylmorpholine is a positive interferent. Field testing of the sampler against a reference impinger technique indicated a positive bias when **toluene** diisocyanate is aerosolized.

Environmental Fate/Exposure Summary:

Commercial **toluene** diisocyanate (TDI) is composed of 2 isomers. 2,4-**Toluene** diisocyanate constitutes roughly 80% of TDI, the other 20% being the 2,6-isomer. It may be released to the environment as fugitive emissions and from stack exhaust during the production, transport, and use of TDI in the manufacture of polyurethane foam products and coatings as well as from spills. The types of reactions which the isomers undergo are similar, although the rates may differ. The reactivity of the 2,4-**toluene** diisocyanate with active hydrogen is greater than with the 2,6-isomer, therefore the percentage of 2,4-**toluene** diisocyanate in monitored TDI is generally much less than the 80% in the commercial mixture. However, since much of the monitoring data do not distinguish between isomers, it is not possible to know the proportion of the isomers in the TDI. If spilled on wet land, TDI is rapidly degraded. In one experiment simulating a spill, 5.5% of the original material remained after 24 hours and in a field situation, the concentration of TDI had declined to the ppm levels in 12 weeks. If released into water, a crust forms around the liquid TDI and <0.5% of the original material remains after 35 days. Low concentrations of TDI disappear from the aqueous environment in approximately a day. In the atmosphere, TDI reacts with photochemically produced hydroxyl radicals (half-life 3.3 hr) and is also removed by dry deposition. Human exposure is primarily occupational via inhalation and dermal contact. (SRC)

Human Toxicity Excerpts:

A survey of the incidence of occupational asthma in a steel coating factory was conducted. The survey was prompted by two male employees developing symptoms suggestive of occupational asthma. The cohort consisted of 221 males employed in the coating shop. A respiratory questionnaire was administered. Spirometric tests were conducted. Peak expiratory flow rate studies were performed on 50 subjects. Twenty one subjects reported symptoms of occupational asthma. Sixty three had other work related symptoms and 58 had respiratory symptoms unrelated to work. The mean length of employment of the subjects with asthmatic symptoms was 7.7 years. All symptomatic subjects had significantly reduced 1 second forced expiratory volumes, compared to asymptomatic workers. 21% of the peak expiratory flow rates were indicative of work related asthma. Two symptomatic subjects were administered inhalation challenge tests with **toluene** diisocyanate after it was discovered that one of the coatings that had been used for 8 years released **toluene** diisocyanate during the coating process. Both subjects showed decreases in forced expiratory volumes of at least 15% below the baseline values. Environmental sampling for **toluene** diisocyanate indicated concentrations ranging from below 0.001 to 0.026 ppm. The coating containing **toluene** diisocyanate was removed from the process. A follow-up survey conducted 1 year later showed that 17 of the symptomatic subjects had become asymptomatic or improved.

Human Toxicity Excerpts:

The prevention of airway inflammation caused by **toluene** diisocyanate by prednisone was studied. Healthy **toluene** diisocyanate sensitive individuals were exposed to 0.018 ppm **toluene** diisocyanate in a test chamber. Bronchoalveolar lavage fluid was collected with a flexible fiberoptic bronchoscope. The lavage fluid was spun in a cytocentrifuge and stained with May/Grunwald/Giemsa for differential cell count. The total cell count was performed on resuspended cell pellets. A late asthmatic response was characterized by the occurrence of less than 20% of free expiratory volume in 1 second. The airway responsiveness was assessed by the reaction to methacholine. The cumulative dose of methacholine that produced a 20% decrease in forced expiratory volume in 1 second was used to measure airway responsiveness. Five subjects who received no prednisone treatment developed a late or dual asthmatic reaction. The albumin concn and total number of cells increased in subjects that were given no prednisone compared to controls. There was a significant increase in the number of neutrophils and a small increase in eosinophilia. There was no significant difference in the counts of other cell types. Results suggest that **toluene** diisocyanate induce late asthmatic reactions causing airway inflammation and that prednisone inhibits these reactions.

Metabolism/Metabolites:

Epithelial injury and inflammation are involved in airway hyperresponsiveness and asthma induced by **toluene** diisocyanate. In that isocyanates are insoluble and highly reactive compounds, bronchial epithelial cells may represent the most important target cells of their toxic effect. We hypothesized that damage to airway epithelium by **toluene** diisocyanate may result in the release of metabolites of arachidonic acid, which are known to promote inflammation and to alter epithelial cell function and airway smooth muscle responsiveness. To test this hypothesis we examined eicosanoid products in the culture media of bronchial epithelial cells exposed in vitro to 8 and 18 ppb **toluene** diisocyanate. Epithelial cells derived from human bronchi obtained at surgery were cultured to confluency on collagen-coated microporous membranes. Those cells, which expressed differentiated characteristics of epithelial cells (they showed keratin-containing filaments and had a cobblestone appearance), were alternatively exposed to **toluene** diisocyanate or air for 30 min in a specially designed in vitro chamber. The production of metabolites of arachidonic acid was assessed by measuring the release of immunoreactive products into the cell medium at the end of the exposure and during a 2 hr period after exposure. This method revealed a predominant isocyanate induced release of immunoreactive 15-hydroxyeicosatetraenoic acid. Release rate of this compound tended to be dose-related and was associated with cell damage as assessed by the release of lactate dehydrogenase in the medium. The following Overview, *** **TOLUENE** DIISOCYANATE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Toluene** diisocyanate is an irritant to skin, lungs, conjunctiva and gastrointestinal tract. Euphoria, ataxia, mental aberrations, sensitization (primarily respiratory), bronchitis, emphysema and cor pulmonale can occur.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Severe conjunctival irritation and lacrimation from liquid or high vapor concentrations is likely. Lower concentrations may produce a burning or prickling sensation.
- Glaucoma and iridocyclitis have been reported with a splash accident.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Burning or irritation of the nose and throat, cough, laryngitis, chest pain, and asthmatic syndrome (chemical bronchitis with severe bronchospasm), sensation of oppression or constriction of the chest, bronchitis, emphysema and cor pulmonale may occur.
- Respiratory symptoms may recur several years after discontinuation of exposure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute exposures may produce headache, insomnia, euphoria, ataxia, anxiety neurosis with depression, or paranoid tendencies.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Inhalation of vapor or aerosol may produce vomiting and abdominal pain. Epigastric and substernal pain may be secondary to the paroxysmal or persistent cough associated with inhalation.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Irritation and inflammation are common. Dermal absorption is low.

IMMUNOLOGIC

0.2.19.1 ACUTE EXPOSURE

- Elevated specific IgE and IgG antibodies have been detected in sensitized and exposed workers. The presence of antibodies does is an indicator of exposure but not of sensitization.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- **Toluene** diisocynate has been classified as a 2B agent: possibly carcinogenic to humans, based on sufficient evidence of carcinogenicity in experimental animals and no human data (IARC, 1987).

0.2.21.2 HUMAN OVERVIEW

- **Toluene** diisocyanate is considered a suspected or possible human carcinogen, based on sufficient evidence of carcinogenicity or tumors (spleen, subcutaneous, hepatic, ovarian, peritoneum, mammary gland tissues) in experimental animals (IARC, 1987; US DHHS, 1994; ACGIH, 1995).

Laboratory:

- Monitor respiratory function closely.

Treatment Overview:

ORAL EXPOSURE

- Due to the irritant nature of this substance, emesis is not advised.
- DILUTION: Immediately dilute with 4 to 8 ounces (120 to 240 mL) of milk or water (not to exceed 15 mL/kg in a child).
- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- Monitor patient for respiratory distress. If a cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis and pneumonia.
- Allergic reaction: Sensitized individuals should be cautioned to avoid further exposure as serious allergic reactions may result.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- Randomized, double-blind cross-over studies showed minimal efficacy of bronchodilators. This could be due to the absence of airway hyperresponsiveness in some TDI-induced asthma.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Available dose-response information concerning humans pertains to inhalational exposure. Concentrations of 2.5 ppm are considered Immediately Dangerous to Life or Health. A fatality in an asthmatic who continued exposure to TDI has been reported.
- The recommended short term exposure limits for TDI in industry is 0.02 ppm. TDI does not have sufficient warning properties (e.g. odor or eye irritancy) at air concentrations below the recommended short term exposure limit.

National Toxicology Program Studies:

Groups of 50 female F344/N rats and 50 female B6C3F1 mice were administered commercial grade **toluene** diisocyanate (80% 2,4- and 20% 2,6-) in corn oil by gavage at doses of 60 or 120 mg/kg body weight, 5 days per week for 105 or 106 weeks. Groups of 50 male F344/N rats received 30 or 60 mg/kg and groups of 50 male B6C3F1 mice received 120 or 240 mg/kg on the same schedule. Dosage analyses of **toluene** diisocyanate indicated that the chemical had reacted in the corn oil vehicle, resulting in actual gavage concentrations 77% to 90% of theoretical values. Groups of 50 rats and 50 mice of each sex received corn oil only and served as vehicle controls. Survival in all groups of dosed rats in the 2-year studies was shorter (P less than or equal to 0.005) than that of the controls; depressions in mean body weight gain relative to controls were greater than 10% in all dosed rat groups throughout most of the study. A dose-dependent pattern of cumulative toxicity began at 70 weeks and culminated in excessive mortality, indicating the estimated maximum tolerated dose had been exceeded for rats. Acute bronchopneumonia occurred at increased incidences in groups of dosed male and female rats (males: control, 2/50; low dose, 6/50; high dose, 14/50; females: 1/50, 10/50, 25/49). /Results indicated that/ commercial grade **toluene** diisocyanate in corn oil was carcinogenic for F344/N rats, causing subcutaneous fibromas and fibrosarcomas (combined) in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland fibroadenomas in females. **Toluene** diisocyanate was not carcinogenic for male B6C3F1 mice. TDI was carcinogenic for female B6C3F1 mice, causing hemangiomas or hemangiosarcomas (combined), as well as hepatocellular adenomas.
[DHHS/NTP; Toxicology and Carcinogenesis Studies of Commercial Grade 2,4 (80%) and 2,6 (20%) - Toluene Diisocyanate (Gavage Studies) p. 7 (1986) Technical Rpt Series No. 251 NIH Pub No. 86-2507]**PEER REVIEWED**

Human Toxicity Excerpts:

The importance of airways inflammation for the development of bronchial hyperresponsiveness and for exacerbation of asthma was investigated in subjects with occupational asthma. Subjects sensitized to isocyanates, a small molecular weight compound that causes occupational asthma were examined. Studies in asthmatic subjects sensitized to **toluene** diisocyanate demonstrated that late, but not early, asthmatic reactions induced by **toluene** diisocyanate were associated with an acute increase in bronchial responsiveness, and with a marked infiltration of neutrophils and a slight infiltration of eosinophils into the airways, both prevented by steroids. As the late asthmatic reactions and the increase in responsiveness induced by **toluene** diisocyanate were prevented by steroids, but not by indomethacin, it was speculated that cell membrane phospholipid metabolites, which are inhibited by steroids but not by indomethacin, may be involved in **toluene** diisocyanate induced hyperresponsiveness. The results of these studies suggest that bronchial hyperresponsiveness and exacerbation of asthma may be related to inflammation of the airways and that cell membrane phospholipid metabolites may be involved.

Human Toxicity Excerpts:

Fifty seven polyurethane foam manufacturing workers and 24 reference workers were followed for 4 yr to clarify the effects on pulmonary function of working in polyurethane foam factories with exposure to **toluene** diisocyanate. No significant differences in the average annual losses of pulmonary function for 4 yr were observed among the 28 polyurethane foam workers whose **toluene** diisocyanate exposure levels were very low (mean = 0.1 ppb, group L), the remaining 29 polyurethane foam workers with mean **toluene** diisocyanate exposure of 5.7 ppb (group H), and the reference workers. However, 15 polyurethane foam workers in group H who had experienced peak exposure excursions to 30 ppb or above with a mean concn of 8.2 ppb showed significantly larger average annual losses in percentage maximal mid-expiratory flow, forced expiratory volume in 1 sec ratio to vital capacity, and forced expiratory flow at 25% of forced vital capacity than expected, and significantly larger average annual losses in some obstructive pulmonary function indices than those of the 14 remaining polyurethane foam workers in group H whose peak exposure excursion levels were 3-14 ppb with a mean time-weighted average of 1.7 ppb, group L, and the reference workers. These findings suggest that the peak exposure excursion level of **toluene** diisocyanate might be important in inducing obstructive pulmonary function changes in the polyurethane foam workers rather than the TWA exposure levels, though further comparative studies of the AAL in those who are exposed to different peak exposure excursion levels but the same mean exposure levels are necessary. From the standpoint of prevention, the proposition that peak exposure excursion levels exceeding 20 ppb should be avoided is reasonable.

Human Toxicity Excerpts:

The clinical findings and the results of inhalation challenge with **toluene** diisocyanate and methacholine in 113 subjects with a history of exposure to **toluene** diisocyanate and work-related respiratory symptoms are reported. Only some of the subjects (40.7%) had isocyanate asthma, diagnosed by a positive **toluene** diisocyanate inhalation challenge. Most reactors had a dual (30.4%) or a late (41.3%) response. The interval between the last occupational exposure and the specific challenge was significantly shorter in reactors, and among this group the number of immediate reactions to **toluene** diisocyanate decr progressively with an incr interval. The reactors had a significantly higher proportion of positive responses to methacholine and a significantly lower mean PD[1][5] FEV[1] (provocative dose of methacholine which provoked a 15% decrease in forced expiratory volume in 1 second): reactors 557:g, SEM 92.3; non-reactors 1346:g, SEM 128, P < .01. Methacholine challenge could not identify subjects with isocyanate asthma.

Human Toxicity Excerpts:

To evaluate the morphologic basis of the different outcomes of **toluene** diisocyanate asthma after quitting occupational exposure, ten patients with **toluene** diisocyanate asthma were examined who showed, at diagnosis, a positive **toluene** diisocyanate challenge test and nonspecific bronchial hyperresponsiveness to methacholine. After diagnosis, all patients ceased work and a 4 to 40 mo follow-up was obtained with three to eight determinations of the cumulative dose producing a 15% fall in forced expiratory volume in 1 second to methacholine in each patient. Bronchoalveolar lavage and biopsy of bronchial muscosa were performed 3 to 39 mo after cessation of work, in the absence of acute exacerbations of the disease. Total cell count in bronchoalveolar lavage fluid was moderately increased in four of ten patients, eosinophils were increased in five of ten patients, and neutrophils were increased in eight of ten patients. Mucosal biopsy specimens of main or lobar bronchi were available in eight of ten patients; epithelial damage and thickening of basement membrane was observed in almost all patients, as well as a mild to moderate inflammatory reaction in the submucosa, mainly represented by lymphocytes, eosinophils, and neutrophils. No relationship was observed between the cellularity of bronchoalveolar lavage and the degree of nonspecific bronchial hyperresponsiveness at the time of bronchoalveolar lavage; mean values of total cells and differential count were not different between patients with presence or absence of the different histologic findings. Mucosal biopsy and bronchoalveolar lavage were performed also in four subjects exposed to dusts without respiratory symptoms or nonspecific bronchial hyperresponsiveness; similar findings were obtained except for the absence of eosinophils in bronchoalveolar lavage and a lesser degree of basement membrane thickening and inflammatory reaction in the submucosa. The study of the changes in nonspecific bronchial hyperresponsiveness after quitting exposure showed that five of ten patients had a significant improvement in nonspecific bronchial hyperresponsiveness to methacholine, as evaluated by a positive significant linear regression between months of work cessation and forced expiratory volume in 1 sec of methacholine; only one of these five patients had an increased number of eosinophils in bronchoalveolar lavage fluid. By contrast, four of the five patients with persistent nonspecific bronchial hyperresponsiveness after quitting exposure had an increased number of eosinophil in bronchoalveolar lavage. It is suggested that persistent nonspecific bronchial hyperresponsiveness in **toluene** diisocyanate asthma after cessation of work may be related to an inflammatory reaction in which eosinophil infiltration seems to be a major determinant.

Human Toxicity Excerpts:

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint materials containing **toluene** diisocyanate. His symptoms began 6 to 8 hr after exposure to the agent and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate-human serum albumin was present in bronchoalveolar lavage fluid and sera: IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate-human serum albumin. The histologic findings suggested hypersensitivity pneumonitis. The results of bronchoalveolar lavage, which was repeated on four separate occasions, showed lymphocytosis and a predominance of suppressor cytotoxic T cells. The findings from serial determinations of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to the agent.

Human Toxicity Excerpts:

A case of building related health complaints was investigated with respect to the relationship among frequency of symptoms, antibodies to albumin conjugates of formaldehyde, **toluene** diisocyanate, and trimellitic anhydride, and volatile organic chemicals. The indoor air concn of volatile organic chemicals, formaldehyde, **toluene** diisocyanate and trimellitic anhydride did not exceed Fed-OSHA and ACGIH permissible standards. However, formaldehyde concn ranged between 0.05 and 0.08 ppm. The reported symptoms were multiple, involving the eyes, nose, sinuses, throat, lungs, skeletomuscular system and central nervous system. Anti-formaldehyde, **toluene** diisocyanate, and trimellitic anhydride isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. The data suggest that a synergistic immunological response to airborne chemicals may be occurring in these subjects. In conclusion, immunological monitoring of affected individuals where chemicals are suspected may prove to be useful in future investigations of building related illness.

Mechanism of Action:

The in vivo exposure to an asthmogenic stimulus, **toluene** diisocyanate, causes airway epithelial damage associated with inflammation and increased bronchial hyperresponsiveness. The latter mechanisms might partly be mediated by the release of eicosanoids from bronchial epithelial cells. Previously it has been demonstrated that the in vitro exposure of bronchial epithelial cells to **toluene** diisocyanate results in the release of immunoreactive 15-hydroxyeicosatetraenoic acid, a product of activation of the 15-lipoxygenase pathway with inflammatory properties. Present study shows that **toluene** diisocyanate induced release of 15-hydroxyeicosatetraenoic acid from epithelial cells can be prevented by nedocromil sodium, an anti-asthmatic drug with anti-inflammatory properties. This mode of action of the compound may explain its clinical effectiveness in asthma.

Human Toxicity Excerpts:

Thirty factory workers whose annual exposure to **toluene** diisocyanate amounted to 280 hr were examined. Seven of them had been removed from their jobs for presenting respiratory symptomatology and a further five were removed for presenting bronchial asthma. Their medical histories were consulted and further measures were taken such as a radiological thorax study, total immunoglobulin-E, **toluene** diisocyanate, diphenylmethane diisocyanate and hexamethylene diisocyanate RAST, a basal spirometric study and finally a provocation test. The Rast proved negative in every case. In the spirometric study carried out on the provocation test, four cases showed a significant decrease in the forced expiratory volume in 1 second over 20% and over 40% in the FMEF and PEFR. There was no connection between the four patients who presented an elevated total immunoglobulin-E and the four who presented a positive provocation test. The provocation test proved negative in five of the seven patients removed from their places of work. Two of the four workers who responded positively to the provocation test remained in their places of work during the **toluene** diisocyanate foam test without showing any symptoms. The patients who presented symptoms did not appear to present bronchial obstruction during the provocation test. Nonetheless, patients who seemingly had not shown any symptoms presented what appeared to be bronchial obstruction.

Human Toxicity Excerpts:

The nature of neurohumoral regulation was studied in 125 healthy workers, aged 20-40 yr, with different length of service and **toluene** diisocyanate exposure levels. Adrenal gland activity and some haematological parameters were determined. Neurohumoral regulation of adaptation processes in **toluene** diisocyanate exposed persons seemed to display some cyclicity, somehow related to the length of service. Two early regulatory phases (service up to 3 yr) had common features unrelated to the exposure levels, while after 3 yr of employment some dissimilarities evolved which did depend on the **toluene** diisocyanate exposure levels.

Human Toxicity Excerpts:

Toluene diisocyanate is commonly used as the 2,4 and 2,6 isomers. NIOSH has estimated that 50,000 to 100,000 workers in the United States are regularly exposed to diisocyanates. As of 1977, 49,996 were estimated to be exposed to **toluene** diisocyanate alone. Methods for measuring diisocyanate exposures were considered. The current American Conference of Governmental Industrial Hygienists' recommended standard is 0.005 ppm time weighted average and 0.02 ppm peak for four 15 min periods a day. Results of exposure measurements taken in industry were summarized. Health effects of diisocyanates were discussed. In laboratory animals, **toluene** diisocyanate has caused inflammation and necrosis when applied directly to the skin, conjunctivitis when applied to the eyes, and rhinitis, laryngitis, tracheitis, bronchitis, and pneumonia when inhaled. Diisocyanates are potent pulmonary sensitizers capable of causing isocyanate asthma in humans. They can induce nonspecific airways disease and hypersensitivity pneumonitis after either acute or chronic exposure.

Human Toxicity Excerpts:

A 46 yr old man who had worked in a paint processing plast for over 29 yr was admitted to our hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonitis due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against **toluene** diisocyanate-human serum albumin and diphenylmethane diisocyanate-human serum albumin, precipitating antibody against **toluene** diisocyanate-human serum albumin, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coombs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggests the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.

Mechanism of Action:

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concn ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concn of tolyl group after 72 hr and persists at a nanomolar level even 2 wk following the exposure. The initial rate of (14)C uptake is also a linear function of the concn of **toluene** diisocyanate when expressed either as concn (ppm) or as concn multiplied by duration of exposure (ppm.hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm.hr. Finally, the inclusion of the data on methyl isocyanate indicates that the uptake into arterial blood is a function of exposure concn, independent of isocyanate structure.

Environmental Abiotic Degradation:

Toluene diisocyanate reacts readily with compounds containing active hydrogens, such as water, acids, and alcohols(2). Contact with bases may cause uncontrollable polymerization with rapid evolution of heat(2). In concentrated solutions, hydrolysis of one of the isocyanate groups to the amine is followed by rapid reaction of the amine with an isocyanate group on another molecule leading to dimers, oligimers, and polymers(2). In one experiment the hydrolysis product yield was 20% diamine and 80% polyurea(3). When 50 ppm of **toluene** diisocyanate was added to model river and seawater systems, the concn fell to 0.1 ppm or less at the end of 1 day(1).

Human Toxicity Excerpts:

The respiratory status of factory workers exposed continously to isocyanates over 10 years was studied. A total of 80 workers in two facilities that manufactured fixtures used in the interiors of cars were examined and underwent spirometry before and after work. Of these, 12 were comparisons not exposed to **toluene** diisocyanate. Subjects included those previously examined in 1971. Ventilatory capacity tests were performed inlcuding forced expiratory volume in 1 sec and forced vital capacity testing. Annual decrements were calculated. The mean average concentration of **toluene** diisocyanate was not more than 0.0033 ppm respectively. Subjects who had been studied previously had a mean forced vital capacity of 104.6% and a mean forced expiratory volume in 1 sec of 107% of predicted values. Three subjects with significant obstruction in the lung function tests were smokers. The comparisons in facility 1 had a significantly lower percentage of the predicted forced fital capacity and forced expiratory volume than the exposed population. Most of the data from 1971 for annual decrement calculations were not reliable. A 10% decrement in forced vital capacity and forced expiratory volume in 1 second was indicative of significant postshift decline and would indicate the presence of isocyanate asthma or hypersensitivity; no subject at either facility met the criteria.

Human Toxicity Excerpts:

Sensitized subjects may develop symptoms of asthma after exposure to isocyanates in their place of work. After challenge with isocyanates in the laboratory, sensitized subjects develop immediate, late and dual asthmatic reactions. **Toluene** diisocyanate might cause late asthmatic reactions and increase bronchial responsiveness by causing an acute inflammatory reaction in the airways, and that airway inflammation may be responsible for persistence of occupational asthma induced by isocyanates. To test these hypotheses, sensitized subjects were examined during asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. It was observed that late and dual, but not early, asthmatic reactions are associated with a transient increase of bronchial responsiveness which is associated with an acute inflammatory reaction of the airways characterized by an increase of neutrophils followed by eosinophils, by an increase of leukotriene B4 and albumin in bronchoalveolar lavage fluid, and that all these effects are inhibited by steroids. Longitudinal studies suggest that the majority of subjects with occupational asthma continue to have persistent asthma months and yrs after the cessation of exposure, and the results of our studies combined with the results of studies performed by others suggest that the persistence of asthma may be related to the persistence of airway inflammation.

Human Toxicity Excerpts:

Twelve subjects were studied with inhalation challenge testing to **toluene** diisocyanate because of suspected asthma based on a consistent clinical and occupational history. In seven cases, asthma was documented by a positive inhalation challenge to low levels of **toluene** diisocyanate. Six of the seven reactors had persistent respiratory symptoms and required daily treatment even though they had been removed from isocyanate exposure for intervals as long as 12 years (mean 4.5 years). These six reactors had either dual (four cases) or late bronchospasm (two cases) to less than 20 ppb and all had a positive methacholine or cold air challenge prior to study. The one reactor with a negative methacholine challenge had a positive (immediate) bronchospastic response to a challenge performed one week after removal from isocyanate exposure. Five workers had a negative challenge, two of whom had persistent respiratory symptoms and positive methacholine challenges at the time of inhalation testing. ... Respiratory symptoms may persist following long-term removal from occupational exposure to and are associated with nonspecific bronchial hyperreactivity. The sensitivity may also persist for a long time even in the absence of any additional occupational exposure. Long-term prospective studies of symptomatic isocyanate workers are needed to fully define the extent of this problem.

Protective Equipment & Clothing:

Facilities for quickly drenching the body should be provided within the immediate work area for emergency use where there is a possibility of exposure. (Note: It is intended that these facilities provide a sufficient quantity or flow of water to quickly remove the substance from any body areas likely to be exposed. The actual determination of what constitutes an adequate quick drench facility depends on the specific circumstances. In certain instances, a deluge shower should be readily available, whereas in others, the availability of water from a sink or hose could be considered adequate.) /**Toluene** 2,4-diisocyanate/

Human Toxicity Excerpts:

Symptoms and lung function of workers exposed to isocyanates in polyurethane foam factories were studied. A group of 67 workers was examined for **toluene**-diisocyanate ... exposure. Measurements were made by samples obtained from subject carried pumps. Interviews were also conducted for information of symptoms involving the nose, eyes, upper airways, and lung. Another group of 56 nonexposed workers was determined by spirometry and nitrogen wash out prior to the work shift. The exposed workers were examined again immediately after work. The variables studied were forced expired vital capacity and forced expired volume in 1 second. ... The highest exposure group was foaming machine workers, with a day mean exposure of 0.023 mg/cu m. Nonsmokers showed an increased frequency of symptoms involving the nose, throat, and dyspnea. Smokers had no significant increase. Smokers of the exposed group reported coughing. Only smokers reported symptoms classified as chronic bronchitis, with frequency independent of exposure. Decreased forced expired vital capacity and forced expired volume were observed in the exposed group. This group also showed increased expired vital capacity. Lung function impairment was restricted to smokers. Spirometric and nitrogen washout variables did not change significantly during the work shift. Decreasing spirometric values with increased exposure was seen in smokers. Conclusions indicate that mean exposure of 0.01 mg/cu m/day to isocyanates may give an increased frequency of symptoms in nonsmokers.

Non-Human Toxicity Excerpts:

Groups of 120 male and 120 female CD-1 mice, three to four weeks old, were exposed to 0, 0.05, or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production grade **toluene** diisocyanate (approx 80% 2,4 isomer & 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 104 wk. There was a significant reduction in body weight in the high-dose group /sex not stated/ and a significant increase in mortality in both high and low-dose females by the termination of the study. No such effect was seen in males. Neither the types of tumor observed nor their incidences were dose-related, and both corresponded to those seen in historical controls for this strain of mice. However, dose-related pathological changes were observed in the nasal cavity (chronic or necrotic rhinitis), together with changes in the lower respiratory tract (interstitial pneumonia, catarrhal bronchitis) in both groups.

Human Toxicity Excerpts:

A shortened protocol was developed for the epidemiological measurement of bronchial responsiveness to methacholine without compromising sensitivity, power, precision or safety, and without distorting the numerical value of the PD20.FEV1 (the cumulative dose from a doubling incremental sequence which provokes a 20% decrement in forced expiratory volume in 1 second). It was used in a survey of 254 polyurethane workers (83% of the eligible workforce) exposed occupationally to **toluene** diisocyanate. The mean duration of each test proved to be 38 min, it was well tolerated and 64 workers (25%) proved to be reactors. PD20.FEV1 appeared to be distributed unimodally. It was significantly correlated with questionnaire records of shortness of breath, chest tightness, and wheeze; and with pre-shift forced expiratory volume in 1 second and FEF25-75. Even the reactors requiring the highest dose of 640 cumulative inhalation units (1 unit = one 8.9 ul inhalation of methacholine 1 mg/ml) to generate a PD20 measurement reported significantly more wheeze than the non-reactors. This indicates that the test had clinical meaning throughout its dose range of 0.3-640 units. No correlation was found between PD20 and individual changes in ventilatory function across the working shift, but mean shift changes were negligible and not statistically significant. PD20 was also found to be unrelated to age, sex, race, smoking, cough and atopy.

RCRA Requirements:

U223; As stipulated in 40 CFR 261.33, when **toluene** diisocyanate, as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Toluene** diisocyanate is produced, as an intermediate or a final product, by process units covered under this subpart.

Mechanism of Action:

Serum immunoglobulin-G and immunoglobulin-E to isocyanate haptenized human serum albumin (HSA) were estimated by ELISA in 55 isocyanate workers who underwent isocyanate inhalation challenge studies in Montreal, Canada. The challenges were negative in 29 workers and positive in 26 workers. Isocyanate antibodies were estimated by ELISA index. The mean immunoglobulin-G indices were found to be significantly higher in the challenge-positive workers, and there was a similar trend for the immunoglobulin-E indices. Antibody specificities for **toluene** diisocyanate-human serum albumin, diphenylmethane diisocyanate-human serum albumin, and hexamethylene diisocyanate-human serum albumin were determined by inhibition studies with a variety of isocyanate haptenized carriers. The other isocyanate substituted carriers were either noninhibitory or caused only partial inhibition as contrasted with the complete inhibition achieved by human serum albumin conjugated to the isocyanate to which the worker was exposed. We interpret these specificity studies as indicating that the inhalation of isocyanates results in production of antibody that recognizes new antigenic determinants that develop from the coupling of isocyanates to homologous proteins.

Human Toxicity Excerpts:

Respiratory variables were measured in workers exposed to **toluene** diisocyanate in Canada. Exposure and effect relationships were studied. Results from 95 isocyanate workers were compared with unexposed workers. Exposed workers were grouped according to production areas based on isocyanate concentrations measured. Individual monitors were worn to identify exposure for some workers. Symptoms and history of respiratory illness were compared through questionnaires. Pulmonary function tests included forced vital capacity, forced expiratory volume in 1 second, and forced expiratory flow at 50% and 75% of vital capacity. Pulmonary function was measured at the beginning and end of work shifts on Monday, Wednesday, and Friday of a work week. Regression analysis of exposure concentration and other variables was attempted. When comparisons were adjusted for smoking habits, exposed workers had a significantly lower family history of respiratory complaints. Isocyanate workers had slightly lower base line lung function than comparisons, but had significantly higher declines in pulmonary function over the work week. A 5% or greater decline over a day occurred in 44 percent of exposed but only 22% of comparison workers. Foam line and finishing area workers had greatest declines in forced vital capacity and forced expiratory volume in 1 second. It was concluded that although regression analysis does not show an exposure/effect relationship, an all or none effect may be operating with acute and chronic compartments. However, sample size may have been insufficient. [Holness DL et al; J Occup Med 26 (6): 449-55 (1984)]**PEER REVIEWED**

A series of workers with exposure to and respiratory symptoms from **toluene** diisocyanate was compared with a group of exposed, asymptomatic workers and with normal controls using immunologic and clinical evaluations. Improved understanding of **toluene** diisocyanate-induced respiratory disease may best be achieved by categorizing the symptomatic workers into at least 3 and possibly 4 groups: immunologic asthma; pre-existing chronic respiratory disease exacerbated or unaffected by **toluene** diisocyanate; asthma coincidental with exposure, and possibly respiratory disease secondary to toxic or inflammatory mechanisms.
[Patterson R et al; Int Arch Allergy Appl Immunol 84 (1): 93-100 (1987)]**PEER REVIEWED**

Subjects exposed to 0.0010 to 0.0015 ppm of **toluene** diisocyanate demonstrated a normal age and smoking-related rate of decline in forced expiratory volume in 1 second and no evidence that it was related to isocyanate exposures.
[Musk AW et al; J Occup Med 27 (12): 917-20 (1985)]**PEER REVIEWED**

Twelve subjects were studied with inhalation challenge testing to **toluene** diisocyanate because of suspected asthma based on a consistent clinical and occupational history. In seven cases, asthma was documented by a positive inhalation challenge to low levels of **toluene** diisocyanate. Six of the seven reactors had persistent respiratory symptoms and required daily treatment even though they had been removed from isocyanate exposure for intervals as long as 12 years (mean 4.5 years). These six reactors had either dual (four cases) or late bronchospasm (two cases) to less than 20 ppb and all had a positive methacholine or cold air challenge prior to study. The one reactor with a negative methacholine challenge had a positive (immediate) bronchospastic response to a challenge performed one week after removal from isocyanate exposure. Five workers had a negative challenge, two of whom had persistent respiratory symptoms and positive methacholine challenges at the time of inhalation testing. ... Respiratory symptoms may persist following long-term removal from occupational exposure to and are associated with nonspecific bronchial hyperreactivity. The sensitivity may also persist for a long time even in the absence of any additional occupational exposure. Long-term prospective studies of symptomatic isocyanate workers are needed to fully define the extent of this problem.

[Moller DR et al; Chest 90 (4): 499 (1986)]**PEER REVIEWED**

Two workers who developed asthmatic symptoms were studied with inhalation provocation tests using ... **toluene** diisocyanate. Subjects did not show asthmatic reations to TDI challenge.
[Mapp CE et al; Ann Allergy 54 (5): 424-9 (1985)]**PEER REVIEWED**

Amine induced asthma was studied in polyurethane foam workers. A total of 12 subjects, occupationally exposed to polyurethane foams, who complained of wheezing and breathlessness at work were tested. Subjects were given 20 to 2000 ug methacholine. Forced expiratory volume in 1 sec was measured. Subjects were challenged with 0.01 ppm **toluene** diisocyanate for 15 min in an atmosphere chamber. Forced expiratory volume in 1 sec was measured. Positive tests were considered as a 15% fall in forced expiratory volume in 1 sec. High sensitivity to methacholine was seen in ten subjects with a 15% fall in forced expiratory volume in 1 sec at <1000 ug; normal subjects responded at 2000 ug. All subjects reacted to **toluene** diisocyanate.
[Cardura F, Moscata G; Brit J Indus Med 41: 552-3 (1984)]**PEER REVIEWED**

... The toxicity of inhaled vapors of diisocyanates is summarized. Humans are exposed to high concentrations of diisocyanates in polyurethane industries. Toxic symptoms are acute inflammation with lachrymation, rhinitis, soreness and burning in the throat and upper part of the chest, and coughing. Fire fighters are particularly prone to these clinical symptoms. The toxic limit value for **toluene** diisocyanate is 0.005 ppm. Exposure to diisocyanates can cause asthma.
[Davies RJ; Clinics in Immunology and Allergy 4 (1): 103-23 (1984)]**PEER REVIEWED**

The respiratory status of factory workers exposed continously to isocyanates over 10 years was studied. A total of 80 workers in two facilities that manufactured fixtures used in the interiors of cars were examined and underwent spirometry before and after work. Of these, 12 were comparisons not exposed to **toluene** diisocyanate. Subjects included those previously examined in 1971. Ventilatory capacity tests were performed inlcuding forced expiratory volume in 1 sec and forced vital capacity testing. Annual decrements were calculated. The mean average concentration of **toluene** diisocyanate was not more than 0.0033 ppm respectively. Subjects who had been studied previously had a mean forced vital capacity of 104.6% and a mean forced expiratory volume in 1 sec of 107% of predicted values. Three subjects with significant obstruction in the lung function tests were smokers. The comparisons in facility 1 had a significantly lower percentage of the predicted forced fital capacity and forced expiratory volume than the exposed population. Most of the data from 1971 for annual decrement calculations were not reliable. A 10% decrement in forced vital capacity and forced expiratory volume in 1 second was indicative of significant postshift decline and would indicate the presence of isocyanate asthma or hypersensitivity; no subject at either facility met the criteria.
[Gee JB; Morgan WKC; J Occup Med 27 (1): 15-8 (1985)]**PEER REVIEWED**

The mechanism by which late asthmatic reactions are induced by **toluene** diisocyanate, a low molecular weight chemical that causes occupational asthma in exposed subjects, is unknown. An investigation was conducted to determine whether early and late asthmatic reactions induced by **toluene** diisocyanate are associated with changes in airway responsiveness to methacholine and airway inflammation as determined by bronchoalveolar lavage. Forced expiratory volume in 1 second was measured before and at regular intervals after exposure to **toluene** diisocyanate and dose-response curves to methacholine and

bronchoalveolar lavage at 8 hr after **toluene** diisocyanate /were performed/ in a group of 6 subjects with late asthmatic reactions and in 6 subjects with only early asthmatic reactions. The same procedure was followed 2 hr after **toluene** diisocyanate in a group of 6 subjects with previously documented late asthmatic reactions and in a group of 6 subjects without any previously documented asthmatic reaction after **toluene** diisocyanate. In subjects with late asthmatic reactions, neutrophils were increased at both 2 hr and 8 hr and eosinophils and airway responsiveness were increased only at 8 hr. By contrast, neutrophils, eosinophils and airway responsiveness were not increased at 8 hr after **toluene** diisocyanate in subjectswith an early asthmatic reaction or at 2 hr after **toluene** diisocyanate in normal control subjects. These results suggest that late asthmatic reactions to **toluene** diisocyanate, and the associated increase in airway responsiveness may be caused by airway inflammation.
[Fabbri LM et al; Am Rev Respir Dis 136 (1): 36-42 (1987)]**PEER REVIEWED**

Technical grade **toluene** diisocyanate induced chromosome aberrations after a 24 hr treatment in the absence of metabolic activation in human whole blood lymphocyte cultures.
[Maki-Paakkanen J, Norppa H; Toxicol Lett 36 (1): 37-43 (1987)]**PEER REVIEWED**

To determine whether late asthmatic reactions and the associated increase in airway induced by **toluene** diisocyanate are linked to airway inflammation, inhibition by prednisone was investigated. Ten "sensitized" subjects were studied in 2 sets of experiments. In the first set, each subject was given no treatment and was studied before and for 8 hr after exposure to **toluene** diisocyanate. In the second set, 2 to 4 wk later, each subject was studied before treatment and then during treatment with prednisone (50 mg once a day for 3 days, orally), both before and after exposure to **toluene** diisocyanate. To assess late asthmatic reactions to **toluene** diisocyanate FEV1 /was measured/ immediately before and after exposure, then hourly for 8 hr. To assess changes in airway responsiveness, a /measurement was made of/ the provocation dose (mg) of methacholine causing a 20% decrease in FEV1 (PD20FEV1) before and 8 hr after exposure to **toluene** diisocyanate. When the subjects received no prednisione treatment, **toluene** diisocyanate caused late asthmatic reactions and increased airway responsiveness. By contrast, when the subjects received prednisone, **toluene** diisocyanate caused no late asthmatic reaction or increased airway responsiveness. Prednisone did not change baseline airway caliber or airway responsiveness. These results suggest that late asthmatic reactions and the associated increase in airway responsiveness induced by **toluene** diisocyanate in "sensitized" subjects may depend on the development of a steroid-responsive acute inflammatory reaction within the airways.
[Fabbri LM; Am Rev Respir Dis 132 (5): 1010-4 (1985)]**PEER REVIEWED**

Case reports of keratophathy in polyurethane production workers were examined. The experimental production of similar conditions was studied in cats and a monkey. Exposure to **toluene** diisocyanate did not result in the clinical appearance of the eye resembling that of the workers.
[Potts AM et al; Am J Indust Med 9 (2): 203-13 (1986)]**PEER REVIEWED**

Symptoms and lung function of workers exposed to isocyanates in polyurethane foam factories were studied. A group of 67 workers was examined for **toluene**-diisocyanate ... exposure. Measurements were made by samples obtained from subject carried pumps. Interviews were also conducted for information of symptoms involving the nose, eyes, upper airways, and lung. Another group of 56 nonexposed workers was determined by spirometry and nitrogen wash out prior to the work shift. The exposed workers were examined again immediately after work. The variables studied were forced expired vital capacity and forced expired volume in 1 second. ... The highest exposure group was foaming machine workers, with a day mean exposure of 0.023 mg/cu m. Nonsmokers showed an increased frequency of symptoms involving the nose, throat, and dyspnea. Smokers had no significant increase. Smokers of the exposed group reported coughing. Only smokers reported symptoms classified as chronic bronchitis, with frequency independent of exposure. Decreased forced expired vital capacity and forced expired volume were observed in the exposed group. This group also showed increased expired vital capacity. Lung function impairment was restricted to smokers. Spirometric and nitrogen washout variables did not change significantly during the work shift. Decreasing spirometric values with increased exposure was seen in smokers. Conclusions indicate that mean exposure of 0.01 mg/cu m/day to isocyanates may give an increased frequency of symptoms in nonsmokers.
[Alexanderson R et al; Internat Archives of Occup Environ Health 55 (2): 149-57 (1985)]**PEER REVIEWED**

A survey of the incidence of occupational asthma in a steel coating factory was conducted. The survey was prompted by two male employees developing symptoms suggestive of occupational asthma. The cohort consisted of 221 males employed in the coating shop. A respiratory questionnaire was administered. Spirometric tests were conducted. Peak expiratory flow rate studies were performed on 50 subjects. Twenty one subjects reported symptoms of occupational asthma. Sixty three had other work related symptoms and 58 had respiratory symptoms unrelated to work. The mean length of employment of the subjects with asthmatic symptoms was 7.7 years. All symptomatic subjects had significantly reduced 1 second forced expiratory volumes, compared to asymptomatic workers. 21% of the peak expiratory flow rates were indicative of work related asthma. Two symptomatic subjects were administered inhalation challenge tests with **toluene** diisocyanate after it was discovered that one of the coatings that had been used for 8 years released **toluene** diisocyanate during the coating process. Both subjects showed decreases in forced expiratory volumes of at least 15% below the baseline values. Environmental sampling for **toluene** diisocyanate indicated concentrations ranging from below 0.001 to 0.026 ppm. The coating containing **toluene** diisocyanate was removed from the process. A follow-up survey conducted 1 year later showed that 17 of the symptomatic subjects had become asymptomatic or improved.
[Venables KM et al; Brit J Indus Med 42 (8): 517-24 (1985)]**PEER REVIEWED**

The presence of different thresholds on bronchial reactivity to **toluene** diisocyanate was tested in 20 spray painters employed in the furniture industry and affected by TDI induced asthma. Bronchial provocation tests failed to demonstrate nonspecific hyperreactivity to methacholine. Exposure of the workers to **toluene** diisocyanate in concentrations ranging from 0.02 to 0.25 ppm demonstrated the occurrence of low, moderate and high thresholds of airways response to **toluene** diisocyanate in nine, seven and four patients, respectively. There was no association between the **toluene** diisocyanate response threshold and the positive response pattern to the lower range of **toluene** diisocyanate levels, but six of the nine patients with low threshold of response to **toluene** diisocyanate and six of the 11

patients with moderate or high thresholds had nonspecific bronchial hyperreactivity. The response to **toluene** diisocyanate also was not associated with the duration of the asthmatic condition, smoking, cessation of work or nonspecific response to methacholine. The pattern of response was not dose dependent in ten of 13 patients who had two positive bronchial provocation tests with different levels of **toluene** diisocyanate, although dual responses were recorded in three patients who had late reactions at low concentrations of **toluene** diisocyanate. The value of forced expiratory volume in one second, recorded during immediate reactions, showed a dose response relationship, in that it declined by 28.4% at lower **toluene** diisocyanate levels as compared to 38.3% following inhalation of higher doses of the compound; no such association was established for the late reaction to **toluene** diisocyanate. The results conclude that patients who are sensitive to **toluene** diisocyanate may have different thresholds of response to the agent.
[Paggiaro PL et al; Respiration 50 (3): 167-73 (1986)]**PEER REVIEWED**

Respiratory variables were measured in workers exposed to **toluene** diisocyanate in Canada. Exposure and effect relationships were studied. Results from 95 isocyanate workers were compared with unexposed workers. Exposed workers were grouped according to production areas based on isocyanate concentrations measured. Individual monitors were worn to identify exposure for some workers. Symptoms and history of respiratory illness were compared through questionnaires. Pulmonary function tests included forced vital capacity, forced expiratory volume in 1 second, and forced expiratory flow at 50% and 75% of vital capacity. Pulmonary function was measured at the beginning and end of work shifts on Monday, Wednesday, and Friday of a work week. Regression analysis of exposure concentration and other variables was attempted. When comparisons were adjusted for smoking habits, exposed workers had a significantly lower family history of respiratory complaints. Isocyanate workers had slightly lower base line lung function than comparisons, but had significantly higher declines in pulmonary function over the work week. A 5% or greater decline over a day occurred in 44 percent of exposed but only 22% of comparison workers. Foam line and finishing area workers had greatest declines in forced vital capacity and forced expiratory volume in 1 second. It was concluded that although regression analysis does not show an exposure/effect relationship, an all or none effect may be operating with acute and chronic compartments. However, sample size may have been insufficient.

All workers develop eye, nose, and throat irritation at 0.5 ppm. Sensitized individuals may manifest symptoms at levels as low as 0.02 ppm.
[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 880]**PEER REVIEWED**

A worker developed **toluene** diisocyanate induced asthma in 1974. On reassessment, 11 yr after leaving the chemical plant where **toluene** diisocyanate was produced, he had no respiratory symptoms and normal bronchial reactivity in response to methacholine, and showed no reaction when challenged with a

subirritant concn of **toluene** diisocyanate. He developed asthma within five months of returning to the workplace. Repeat challenge testing showed bronchial hyperreactivity to methacholine and to the specific sensitising agent, **toluene** diisocyanate. This clinical pattern could be due to underlying **toluene** diisocyanate sensitivity with resolution and reappearance of hyperresponsiveness to methacholine and **toluene** diisocyanate reactivity associated with workplace **toluene** diisocyanate exposure. Alternatively, this worker may have developed sensitisation to **toluene** diisocyanate anew.
[Banks DE, Rando RJ; Thorax 43 (8): 1988 660-2]**PEER REVIEWED**

An investigation of the persistence of isocyanate induced asthma in workers with negligible occupational exposure was carried out. Six asthmatic workers, proven to be **toluene** diisocyanate sensitive by inhalation challenge testing in a longitudinal study of respiratory health risks associated with polyurethane foam production, were examined. The subjects were followed for 5 yr during which they completed a respiratory symptom questionnaire annually. Pulmonary function and responsiveness to methacholine challenge were measured annually. **toluene** diisocyanate concn in their breathing zones were measured. After the original survey the six subjects were transferred to areas thought to have negligible **toluene** diisocyanate exposures. None of the subjects had respiratory or asthmatic complaints before they started work in polyurethane production. The respiratory symptoms of the subjects did not improve during the followup period. All six had bronchial hyperresponsiveness to methacholine that did not resolve over time. Three subjects demonstrated deficits in 1 second forced expiratory volume of greater than 15% on one of the testing days during the followup period. The need for less or additional asthma therapy of the subjects could not be predicted. The mean time weighted average **toluene** diisocyanate exposure experienced by the subjects was 0.64 ppb; less than 5% of the OSHA standard of 20 ppb. It was concluded that although the outcome of isocyanate induced asthma cannot be predicted, the asthmatic symptoms of these workers have persisted despite the negligible **toluene** diisocyanate exposures.
[Banks DE et al; Chest 97 (1): 121-5 (1990)]**PEER REVIEWED**

The prevention of airway inflammation caused by **toluene** diisocyanate by prednisone was studied. Healthy **toluene** diisocyanate sensitive individuals were exposed to 0.018 ppm **toluene** diisocyanate in a test chamber. Bronchoalveolar lavage fluid was collected with a flexible fiberoptic bronchoscope. The lavage fluid was spun in a cytocentrifuge and stained with May/Grunwald/Giemsa for differential cell count. The total cell count was performed on resuspended cell pellets. A late asthmatic response was characterized by the occurrence of less than 20% of free expiratory volume in 1 second. The airway responsiveness was assessed by the reaction to methacholine. The cumulative dose of methacholine that produced a 20% decrease in forced expiratory volume in 1 second was used to measure airway responsiveness. Five subjects who received no prednisone treatment developed a late or dual asthmatic reaction. The albumin concn and total number of cells increased in subjects that were given no prednisone compared to controls. There was a significant increase in the number of neutrophils and a small increase in eosinophilia. There was no significant difference in the counts of other cell types. Results suggest that **toluene** diisocyanate induce late asthmatic reactions causing airway inflammation and that prednisone inhibits these reactions.
[Boschetto P et al; J Allergy Clin Immunol 80 (3):261-267 (1987)]**PEER REVIEWED**

Two men were exposed to **toluene** diisocyanate atmospheres at three different air concn (ca 25, 50 and 70 ug/cu m). The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8-cu m stainless-steel test chamber. The effective exposure

period was 4 hr. The isomeric composition of the air in the test chamber was 30% 2,4-**toluene** diisocyanate and 70% 2,6-**toluene** diisocyanate. The concn of **toluene** diisocyanate in air of the test chamber was determined by an HPLC method using the 9-(N-methyl-amino-methyl)-anthracene reagent and by a continuous-monitoring filter-tape instrument. Following the hydrolysis of plasma and urine, the related amines, 2,4-toluenediamine and 2,6-toluenediamine, were determined as pentafluoropropionic anhydride derivatives by capillary gas chromatography using selected ion monitoring in the electron impact mode. In plasma, 2,4- and 2,6-toluenediamine showed a rapid-phase elimination half-time of ca 2-5 hr, and that for the slow phase was greater than 6 days. A connection was observed between concn of 2,4- and 2,6-**toluene** diisocyanate in air and the levels of 2,4- and 2,6-toluenediamine in plasma. The cumulated amount of 2,4-toluenediamine excreted in the urine over 24 hr was ca 15%-19% of the estimated inhaled dose of 2,4-**toluene** diisocyanate, and that of 2,6-toluenediamine was ca 17%-23% of the inhaled dose of 2,6-**toluene** diisocyanate. A connection was found between the cumulated (24 hr) urinary excretion of 2,4- and 2,6-toluenediamine and the air concn of 2,4- and 2,6-**toluene** diisocyanate in the test chamber.
[Brorson T et al; Int Arch Occup Environ Health 63 (4): 253-9 (1991)]**PEER REVIEWED**

Thirty factory workers whose annual exposure to **toluene** diisocyanate amounted to 280 hr were examined. Seven of them had been removed from their jobs for presenting respiratory symptomatology and a further five were removed for presenting bronchial asthma. Their medical histories were consulted and further measures were taken such as a radiological thorax study, total immunoglobulin-E, **toluene** diisocyanate, diphenylmethane diisocyanate and hexamethylene diisocyanate RAST, a basal spirometric study and finally a provocation test. The Rast proved negative in every case. In the spirometric study carried out on the provocation test, four cases showed a significant decrease in the forced expiratory volume in 1 second over 20% and over 40% in the FMEF and PEFR. There was no connection between the four patients who presented an elevated total immunoglobulin-E and the four who presented a positive provocation test. The provocation test proved negative in five of the seven patients removed from their places of work. Two of the four workers who responded positively to the provocation test remained in their places of work during the **toluene** diisocyanate foam test without showing any symptoms. The patients who presented symptoms did not appear to present bronchial obstruction during the provocation test. Nonetheless, patients who seemingly had not shown any symptoms presented what appeared to be bronchial obstruction.
[Duce F et al; Allergol Immunopathol (Madr) 16 (3): 139-44 (1988)]**PEER REVIEWED**

The nature of neurohumoral regulation was studied in 125 healthy workers, aged 20-40 yr, with different length of service and **toluene** diisocyanate exposure levels. Adrenal gland activity and some haematological parameters were determined. Neurohumoral regulation of adaptation processes in **toluene** diisocyanate exposed persons seemed to display some cyclicity, somehow related to the length of service. Two early regulatory phases (service up to 3 yr) had common features unrelated to the exposure levels, while after 3 yr of employment some dissimilarities evolved which did depend on the **toluene** diisocyanate exposure levels.
[Ermakova GA, Kryzanovskaja NA; Gigiena truda i Professional'nye Zabolevanija (7): 22-35 (1988)]**PEER REVIEWED**

Sensitized subjects may develop symptoms of asthma after exposure to isocyanates in their place of work. After challenge with isocyanates in the laboratory, sensitized subjects develop immediate, late and

dual asthmatic reactions. **Toluene** diisocyanate might cause late asthmatic reactions and increase bronchial responsiveness by causing an acute inflammatory reaction in the airways, and that airway inflammation may be responsible for persistence of occupational asthma induced by isocyanates. To test these hypotheses, sensitized subjects were examined during asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. It was observed that late and dual, but not early, asthmatic reactions are associated with a transient increase of bronchial responsiveness which is associated with an acute inflammatory reaction of the airways characterized by an increase of neutrophils followed by eosinophils, by an increase of leukotriene B4 and albumin in bronchoalveolar lavage fluid, and that all these effects are inhibited by steroids. Longitudinal studies suggest that the majority of subjects with occupational asthma continue to have persistent asthma months and yrs after the cessation of exposure, and the results of our studies combined with the results of studies performed by others suggest that the persistence of asthma may be related to the persistence of airway inflammation.
[Fabbri LM et al; Eur Respir J (Suppl 13): 136-38 (1991)]**PEER REVIEWED**

A shortened protocol was developed for the epidemiological measurement of bronchial responsiveness to methacholine without compromising sensitivity, power, precision or safety, and without distorting the numerical value of the PD20.FEV1 (the cumulative dose from a doubling incremental sequence which provokes a 20% decrement in forced expiratory volume in 1 second). It was used in a survey of 254 polyurethane workers (83% of the eligible workforce) exposed occupationally to **toluene** diisocyanate. The mean duration of each test proved to be 38 min, it was well tolerated and 64 workers (25%) proved to be reactors. PD20.FEV1 appeared to be distributed unimodally. It was significantly correlated with questionnaire records of shortness of breath, chest tightness, and wheeze; and with pre-shift forced expiratory volume in 1 second and FEF25-75. Even the reactors requiring the highest dose of 640 cumulative inhalation units (1 unit = one 8.9 ul inhalation of methacholine 1 mg/ml) to generate a PD20 measurement reported significantly more wheeze than the non-reactors. This indicates that the test had clinical meaning throughout its dose range of 0.3-640 units. No correlation was found between PD20 and individual changes in ventilatory function across the working shift, but mean shift changes were negligible and not statistically significant. PD20 was also found to be unrelated to age, sex, race, smoking, cough and atopy.
[Hendrick DJ; Bull Eur Physiopathol Respir 23 (6): 555-9 (1987)]**PEER REVIEWED**

Among the painters handling polyurethane varnish in two furniture manufacturing factories with high **toluene** diisocyanate exposure (0.79 mg/cu m and 0.31 mg/cu m), 26.3% and 15% subjects, respectively displayed asthmatic symptoms, lung function loss, and an increment in mast cell degranulation percentage specific to **toluene** diisocyanate. Some cases of **toluene** diisocyanate linked contact dermatitis were also found among them, being elucidated by positive patch testing to **toluene** diisocyanate. However, the previous abnormalities could not be verified among the painters from another factory with **toluene** diisocyanate concn below the TLV of it (0.11 mg/cu m). It was concluded that both pulmonary hypersensitivity and contact sensitization to **toluene** diisocyanate had occurred in some of the painters included in this study, and that the immunologic effects of **toluene** diisocyanate was concn dependent.
[Huang J et al; Arch Environ Contam Toxicol 21 (4): 607-11 (1991)]**PEER REVIEWED**

The importance of airways inflammation for the development of bronchial hyperresponsiveness and for

exacerbation of asthma was investigated in subjects with occupational asthma. Subjects sensitized to isocyanates, a small molecular weight compound that causes occupational asthma were examined. Studies in asthmatic subjects sensitized to **toluene** diisocyanate demonstrated that late, but not early, asthmatic reactions induced by **toluene** diisocyanate were associated with an acute increase in bronchial responsiveness, and with a marked infiltration of neutrophils and a slight infiltration of eosinophils into the airways, both prevented by steroids. As the late asthmatic reactions and the increase in responsiveness induced by **toluene** diisocyanate were prevented by steroids, but not by indomethacin, it was speculated that cell membrane phospholipid metabolites, which are inhibited by steroids but not by indomethacin, may be involved in **toluene** diisocyanate induced hyperresponsiveness. The results of these studies suggest that bronchial hyperresponsiveness and exacerbation of asthma may be related to inflammation of the airways and that cell membrane phospholipid metabolites may be involved.
[Mapp CE et al; Bull Eur Physiopathol Respir 23 (6): 583-6 (1987)]**PEER REVIEWED**

A study of individuals with occupational asthma induced by **toluene** diisocyanate was conducted. This was a followup of 35 patients, 25 males, with a history of isocyanate sensitization. They had 3 to 41 years' occupational exposure to isocyanate compounds. The subjects had been diagnosed with isocyanate asthma on the basis of their response to bronchial challenge with **toluene** diisocyanate. They were examined an average of 11 mo after diagnosis. They underwent bronchial challenge with **toluene** diisocyanate and methacholine. Forced expiratory volumes in 1 second were measured. Symptoms reported by the subjects were recorded. Twenty seven subjects were still asthmatic at followup as shown by a positive reaction to **toluene** diisocyanate challenge. They showed a deterioration in their forced expiratory volumes in 1 second and response to methacholine similar to that seen at diagnosis. Seventy seven percent of these subjects continued to have recurring attacks of dyspnea, wheezing, and cough which required medication. Twenty two of the asthma subjects had been removed from exposure. Subjects who recovered (did not react to **toluene** diisocyanate at the followup examination) showed an improvement in their forced expiratory volumes in 1 second and a reduced response to methacholine. At the time of diagnosis they tended to have an immediate or dual asthmatic reaction and were younger than the other subjects. The asthmatic subjects had dual or late reactions at diagnosis. It was concluded that respiratory symptoms, isocyanate sensitization, and airway hyperresponsiveness may persist for some time after exposure to **toluene** diisocyanate has ended.
[Mapp CE et al; Am Rev Respir Dis 137 (6): 1326-9 (1988)]**PEER REVIEWED**

Six workers with occupational asthma due to **toluene** diisocyanate were studied. For each worker a detailed clinical and occupational history was taken, and lung function measurement and skin intradermal tests for common allergens were carried out. Methacholine inhalation challenge was performed before **toluene** diisocyanate inhalation, and 8 hr after **toluene** diisocyanate inhalation. Methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, but went into the asthmatic range after **toluene** diisocyanate inhalation. These cases provid evidence that asthma can be induced by **toluene** diisocyanate in the absence of airway hyperresponsiveness. They further demonstrate that an isolated negative methacholine inhalation test cannot be used to exclude sensitization to **toluene** diisocyanate. Screening and follow-up studies on workers exposed on **toluene** diisocyanate require serial measurements of airway responsiveness and of variable air-flow obstruction.
[Mapp CE et al; Eur J Respir Dis 68 (2): 89-95 (1986)]**PEER REVIEWED**

The clinical findings and the results of inhalation challenge with **toluene** diisocyanate and methacholine in 113 subjects with a history of exposure to **toluene** diisocyanate and work-related respiratory symptoms are reported. Only some of the subjects (40.7%) had isocyanate asthma, diagnosed by a positive **toluene** diisocyanate inhalation challenge. Most reactors had a dual (30.4%) or a late (41.3%) response. The interval between the last occupational exposure and the specific challenge was significantly shorter in reactors, and among this group the number of immediate reactions to **toluene** diisocyanate decr progressively with an incr interval. The reactors had a significantly higher proportion of positive responses to methacholine and a significantly lower mean PD[1][5] FEV[1] (provocative dose of methacholine which provoked a 15% decrease in forced expiratory volume in 1 second): reactors 557:g, SEM 92.3; non-reactors 1346:g, SEM 128, P < .01. Methacholine challenge could not identify subjects with isocyanate asthma.
[Moscato G et al; J Occup Med 33 (6): 720-5 (1991)]**PEER REVIEWED**

Toluene diisocyanate is commonly used as the 2,4 and 2,6 isomers. NIOSH has estimated that 50,000 to 100,000 workers in the United States are regularly exposed to diisocyanates. As of 1977, 49,996 were estimated to be exposed to **toluene** diisocyanate alone. Methods for measuring diisocyanate exposures were considered. The current American Conference of Governmental Industrial Hygienists' recommended standard is 0.005 ppm time weighted average and 0.02 ppm peak for four 15 min periods a day. Results of exposure measurements taken in industry were summarized. Health effects of diisocyanates were discussed. In laboratory animals, **toluene** diisocyanate has caused inflammation and necrosis when applied directly to the skin, conjunctivitis when applied to the eyes, and rhinitis, laryngitis, tracheitis, bronchitis, and pneumonia when inhaled. Diisocyanates are potent pulmonary sensitizers capable of causing isocyanate asthma in humans. They can induce nonspecific airways disease and hypersensitivity pneumonitis after either acute or chronic exposure.
[Musk AW et al; Am J Ind Med 13 (3): 331-49 (1988)]**PEER REVIEWED**

A 46 yr old man who had worked in a paint processing plast for over 29 yr was admitted to our hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonitis due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against **toluene** diisocyanate-human serum albumin and diphenylmethane diisocyanate-human serum albumin, precipitating antibody against **toluene** diisocyanate-human serum albumin, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coombs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggests the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.
[Nozawa S et al; Nippon Kyobu Shikkan Gakkai Zasshi 27 (11): 1335-41 (1989)]**PEER REVIEWED**

Pulmonary function tests were done and compared to current and past potential exposure levels of **toluene** diisocyanate for 57 **toluene** diisocyanate manufacturing workers and 89 workers not exposed to **toluene** diisocyanate or other known respiratory hazards. The average **toluene** diisocyanate plant experience was 4.1 yr (standard deviation = 2.8). Routine industrial hygiene measurements have shown

toluene diisocyanate exposure below a time-weighted average of 0.005 ppm and a short-term exposure level of 0.02 ppm. A certified industrial hygienist ranked department and job classification by level of potential exposure to **toluene** diisocyanate (none, low, moderate, and high). A questionnaire was administered to determine the prevalence of respiratory symptoms and smoking habits. Using backward regression analysis, cumulative pack-years of cigarette smoking and prevalence of lower respiratory symptoms were statistically significant predictors of a standardized forced expiratory volume at 1 second; however, **toluene** diisocyanate exposure, whether classified as current, highest career level, cumulative, or cumulative highest-to-date, was not associated with a decline in forced expiratory volume.
[Olsen GW et al; J Occup Med 31 (8): 664-7 (1989)]**PEER REVIEWED**

Fifty seven polyurethane foam manufacturing workers and 24 reference workers were followed for 4 yr to clarify the effects on pulmonary function of working in polyurethane foam factories with exposure to **toluene** diisocyanate. No significant differences in the average annual losses of pulmonary function for 4 yr were observed among the 28 polyurethane foam workers whose **toluene** diisocyanate exposure levels were very low (mean = 0.1 ppb, group L), the remaining 29 polyurethane foam workers with mean **toluene** diisocyanate exposure of 5.7 ppb (group H), and the reference workers. However, 15 polyurethane foam workers in group H who had experienced peak exposure excursions to 30 ppb or above with a mean concn of 8.2 ppb showed significantly larger average annual losses in percentage maximal mid-expiratory flow, forced expiratory volume in 1 sec ratio to vital capacity, and forced expiratory flow at 25% of forced vital capacity than expected, and significantly larger average annual losses in some obstructive pulmonary function indices than those of the 14 remaining polyurethane foam workers in group H whose peak exposure excursion levels were 3-14 ppb with a mean time-weighted average of 1.7 ppb, group L, and the reference workers. These findings suggest that the peak exposure excursion level of **toluene** diisocyanate might be important in inducing obstructive pulmonary function changes in the polyurethane foam workers rather than the TWA exposure levels, though further comparative studies of the AAL in those who are exposed to different peak exposure excursion levels but the same mean exposure levels are necessary. From the standpoint of prevention, the proposition that peak exposure excursion levels exceeding 20 ppb should be avoided is reasonable.
[Omae K et al; Int Arch Occup Environ Health 63 (8): 565-9 (1992)]**PEER REVIEWED**

To evaluate the morphologic basis of the different outcomes of **toluene** diisocyanate asthma after quitting occupational exposure, ten patients with **toluene** diisocyanate asthma were examined who showed, at diagnosis, a positive **toluene** diisocyanate challenge test and nonspecific bronchial hyperresponsiveness to methacholine. After diagnosis, all patients ceased work and a 4 to 40 mo follow-up was obtained with three to eight determinations of the cumulative dose producing a 15% fall in forced expiratory volume in 1 second to methacholine in each patient. Bronchoalveolar lavage and biopsy of bronchial muscosa were performed 3 to 39 mo after cessation of work, in the absence of acute exacerbations of the disease. Total cell count in bronchoalveolar lavage fluid was moderately increased in four of ten patients, eosinophils were increased in five of ten patients, and neutrophils were increased in eight of ten patients. Mucosal biopsy specimens of main or lobar bronchi were available in eight of ten patients; epithelial damage and thickening of basement membrane was observed in almost all patients, as well as a mild to moderate inflammatory reaction in the submucosa, mainly represented by lymphocytes, eosinophils, and neutrophils. No relationship was observed between the cellularity of bronchoalveolar lavage and the degree of nonspecific bronchial hyperresponsiveness at the time of bronchoalveolar lavage; mean values of total cells and differential count were not different between patients with

presence or absence of the different histologic findings. Mucosal biopsy and bronchoalveolar lavage were performed also in four subjects exposed to dusts without respiratory symptoms or nonspecific bronchial hyperresponsiveness; similar findings were obtained except for the absence of eosinophils in bronchoalveolar lavage and a lesser degree of basement membrane thickening and inflammatory reaction in the submucosa. The study of the changes in nonspecific bronchial hyperresponsiveness after quitting exposure showed that five of ten patients had a significant improvement in nonspecific bronchial hyperresponsiveness to methacholine, as evaluated by a positive significant linear regression between months of work cessation and forced expiratory volume in 1 sec of methacholine; only one of these five patients had an increased number of eosinophils in bronchoalveolar lavage fluid. By contrast, four of the five patients with persistent nonspecific bronchial hyperresponsiveness after quitting exposure had an increased number of eosinophil in bronchoalveolar lavage. It is suggested that persistent nonspecific bronchial hyperresponsiveness in **toluene** diisocyanate asthma after cessation of work may be related to an inflammatory reaction in which eosinophil infiltration seems to be a major determinant.
[Paggiaro P et al; Chest 98 (3): 536-42 (1990)]**PEER REVIEWED**

The effect of cessation of exposure to **toluene** diisocyanate was studied in six patients with **toluene** diisocyanate induced asthma, proved by a positive inhalation challenge with **toluene** diisocyanate. Bronchial challenges with **toluene** diisocyanate and methacholine were performed, and lobar bronchial biopsies were taken at diagnosis and 6 mo later, after cessation of exposure. Biopsies from four nonasthmatic control subjects were also examined. At diagnosis, asthmatic subjects had thickened reticular basement membrane ($p < 0.05$) and increased numbers of mononuclear cells ($p < 0.05$) and eosinophils ($p < 0.05$) in the lamina propria when compared with control subjects. Electron microscopy showed degranulation of eosinophils and mast cells in asthmatics. Six months after cessation of exposure, the thickness of reticular basement membrane was significantly reduced compared with that at diagnosis ($p < 0.05$), and it decr to values similar to those of control biopsies. Inflammatory cell numbers in bronchial mucosa of asthmatic subjects did not change significantly 6 mo after removal from exposure, and degranulation of eosinophils and mast cells was still present. At the end of the study, airwa hyperresponsiveness to methacholine and/or sensitivity to **toluene** diisocyanate persisted in most of the asthmatic patients despite the cessation of exposure and the disappearance of asthmatic symptoms. In conclusion, in patients with occupational asthma induced by **toluene** diisocyanate, the avoidance of exposure to the sensitizing agent for 6 mo is able to reverse the reticular basement membrane thickening in the bronchial mucosa, but th inflammatory cell infiltrate, the specific sensitivity to **toluene** diisocyanate, and the nonspecific airway hyperreactivity may persist.
[Saetta M et al; Am Rev Respir Dis 145 (1): 169-74 (1992)]**PEER REVIEWED**

Forty-three workers exposed to low levels of **toluene** diisocyanate during the process of producing polyurethane forms were examined immunologically for immunoglobulin-G, A, M, and E and serum enzyme activities such as serum angiotensin converting enzyme, serum lysozyme and glycylproline dipeptidyl aminopeptidase. Air concn of **toluene** diisocyanate was annually measured in various places of work during the past five years from 1979 to 1983. The results obtained in the present study were as follows. The air concn of **toluene** diisocyanate at all places of work was below the permissible concn level of 0.02 ppm throughout the study period. Subjective symptoms and abnormal findings on chest X-ray considered directly related to **toluene** diisocyanate exposure were no observed. No remarkable abnormal findings in blood cell counts and in serum biochemical studies could be seen in any of the workers. The serum immunoglobulin-G levels in workers directly exposed to **toluene** diisocyanate were

significantly higher ($p < 0.05$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers. In the study of serum enzymatic activity, serum lysozyme activity in workers exposed directly to **toluene** diisocyanate was significantly higher ($p < 0.01$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers.
[Taniwaki H et al; Sangyo Igaku 29 (2): 130-5 (1987)]**PEER REVIEWED**

A case of building related health complaints was investigated with respect to the relationship among frequency of symptoms, antibodies to albumin conjugates of formaldehyde, **toluene** diisocyanate, and trimellitic anhydride, and volatile organic chemicals. The indoor air concn of volatile organic chemicals, formaldehyde, **toluene** diisocyanate and trimellitic anhydride did not exceed Fed-OSHA and ACGIH permissible standards. However, formaldehyde concn ranged between 0.05 and 0.08 ppm. The reported symptoms were multiple, involving the eyes, nose, sinuses, throat, lungs, skeletomuscular system and central nervous system. Anti-formaldehyde, **toluene** diisocyanate, and trimellitic anhydride isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. The data suggest that a synergistic immunological response to airborne chemicals may be occurring in these subjects. In conclusion, immunological monitoring of affected individuals where chemicals are suspected may prove to be useful in future investigations of building related illness.
[Thrasher JD et al; Am J Ind Med 15 (2): 187-95 (1989)]**PEER REVIEWED**

Diisocyanate inhalation tests (maximal concn, 20 ppb; exposure time, 1-2 hr) were performed using **toluene** diisocyanate (TDI, n = 15) and diphenylmethane diisocyanate (MDI, n = 7) as well as methacholine challenges in 19 workers who had a clinical history of **toluene** diisocyanate/diphenylmethane diisocyanate induced asthma. Additionally volunteers were tested who had n previous contact with diisocyanates: 10 healthy individuals with a negative methacholine test and 14 patients with asthma and a positive methacholine test were exposed to **toluene** diisocyanate. In all, 1 of the normal volunteers and 3 of the patients with asthma unrelated to diisocyanates showed a positive airway reaction to **toluene** diisocyanate, and 13 of the 19 diisocyanate workers displayed a positive result in the **toluene** diisocyanate/diphenylmethane diisocyanate inhalation test; however, only 6 of these 13 individuals reacted to methacholine. Furthermore, 3 of the 6 patients with a negative **toluene** diisocyanate/diphenylmethane diisocyanate challenge test demonstrated a significant response to methacholine. It was concluded that bronchial hyperreactivity as evaluated by the methacholine challenge test is not closely related to isocyanate induced bronchoconstriction and, therefore, the metacholine challenge is only of limited diagnostic value in patients with suspected isocyanate induced asthma.
[Vogelmeier C et al; Int Arch Occup Environ Health 63 (1): 9-13 (1991)]**PEER REVIEWED**

An outbreak of occupational asthma due to **toluene** diisocyanate among industrial workers was described. Four employees at a velcro/like tape manufacturing factory in Taipei, Taiwan were seen in an outpatient clinic complaining of cough, shortness of breath, and wheezing. The symptoms became worse at night and improved after long holidays. The patients' job involved applying an adhesive to the tape. Thirty eight of 45 employees were interviewed by questionnaire and given pulmonary function tests. The pulmonary function tests were given during a workday, after a 10 day holiday, and 5 mo after control measures such as process isolation, improved ventilation, and substitution for **toluene** diisocyanate were instituted. Industrial hygiene sampling for **toluene** diisocyanate was conducted. Fourteen workers had symptoms of asthma or asthmatic bronchitis. The highest attack rate occurred in workers employed in the

tape processing area where the adhesive was applied. Workers in the tape processing area also showed the greatest decr in 1 second forced expiratory volume and forced vital capacity over the workday. Mean **toluene** diisocyanate concn ranged from 0.012 to 0.047 ppm, the highest occurring in the tape processing area and the lowest in the weaving area. The prevalence of asthmatic symptoms was significantly correlated with **toluene** diisocyanate concn. The forced expiratory volume in 1 second and forced vital capacity values were significantly improved after the 10 day holiday and 5 mo after the control methods were instituted. No asthmatic symptoms were reported after 5 mo. It was concluded that **toluene** diisocyanate was responsible for the outbreak and improving the work environment was effective in reducing exposure to **toluene** diisocyanate.
[Wang JD et al; Am J Ind Med 14 (1): 73-8 (1988)]**PEER REVIEWED**

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint materials containing **toluene** diisocyanate. His symptoms began 6 to 8 hr after exposure to the agent and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate-human serum albumin was present in bronchoalveolar lavage fluid and sera: IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate-human serum albumin. The histologic findings suggested hypersensitivity pneumonitis. The results of bronchoalveolar lavage, which was repeated on four separate occasions, showed lymphocytosis and a predominance of suppressor cytotoxic T cells. The findings from serial determinations of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to the agent.

Medical Surveillance:

A SCREENING PROGRAM WAS UNDERTAKEN AT A RESEARCH & DEVELOPMENT FACILITY OF A LARGE **TOLUENE**-DIISOCYANATE (TDI) MANUFACTURING CORPORATION. THE PURPOSE WAS TO DETERMINE THE OCCURRENCE OF ANTIBODIES TO TDI IN SELECTED WORKER POPULATIONS. NO TOLYL-REACTIVE IMMUNOGLOBULIN-E ANTIBODIES WERE DETECTED IN SERA WHEN WORKERS WERE EXPOSED ONLY TO AMBIENT TDI CONCN. WORKERS HAD ACUTE EXPOSURES TO TDI AS A RESULT OF SPILLS OR SPLASHES. ANTIBODY RESPONSES DEVELOPED IN 3 OF 4 INDIVIDUALS WHOSE ACUTE EXPOSURES WERE ACCOMPANIED BY IMMEDIATE RESPIRATORY SYMPTOMATOLOGY & A DECREASED FORCED EXPIRATORY VOLUME. AN ANTIBODY RESPONSE DEVELOPED IN 1 OF 9 WORKERS & IMMEDIATE RESPIRATORY

SYMPTOMS, BUT NO SPIROMETRIC CHANGES UPON ACUTE TDI EXPOSURE. ROUTINE SEROLOGIC SCREENING OF WORKERS FOR TOLYL-REACTIVE ANTIBODIES MAY BE OF VALUE IN CONFIRMING SUSPECTED ISOCYANATE EXPOSURE & IN PROVIDING AN EARLY WARNING OF DEVELOPING TDI HYPERSENSITIVITY.
[KAROL MH; J OCCUP MED 23 (11): 741 (1981)]**PEER REVIEWED**

MEDICAL EVALUATIONS OF 15 WORKERS WERE MADE TO DETERMINE THE HEALTH EFFECTS OF EXPOSURE TO TDI, PHOSGENE & TDA. THE FOLLOWING STEPS WERE RECOMMENDED: THE ENTIRE FACTORY POPULATION SHOULD BE SURVEYED PERIODICALLY FOR SYMPTOMS OF LOWER RESPIRATORY TRACT DISEASES & LUNG FUNCTION ABNORMALITIES THAT MAY BE CAUSED BY CHEMICAL EXPOSURE; TDI EXPOSURE SHOULD BE ENDED FOR SENSITIZED WORKERS OR FOR THOSE WITH EXCESSIVE DECLINE IN LUNG FUNCTION.
[COSTELLO RJ, PETERS JM; HEALTH HAZARD EVALUATION DETERMINATION REPORT NO HE-78-31-623, OLIN CORPORATION, ASHTABULA, OHIO 44004; REPORT NIOSH-HE-78-31-623, ORDER NO PB80-195274 (1979)]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Whenever medical surveillance is indicated, in particular when exposure to a carcinogen has occurred, ad hoc decisions should be taken concerning ... /cytogenetic and/or other/ tests that might become useful or mandatory. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 23]**PEER REVIEWED**

Comprehensive preplacement medical examinations should be given to each employee. The examination should include a pulmonary function test including FEV1, FVC, and FEV1/FVC, a history of diisocyanate exposure, smoking history, and history of respiratory conditions. The medical data obtained in the pre-placement examination can be used as a base line for periodic examination. Periodic examinations may be useful in detecting a reduction in lung function. Lung function tests, pulmonary history, and pulmonary physical exam should be repeated at least annually. All medical records, including pulmonary function and related medical tests, should be maintained for 30 years.
[Zenz, C. Occupational Medicine-Principles and Practical Applications. 2nd ed. St. Louis, MO: Mosby-Yearbook, Inc, 1988. 1019]**PEER REVIEWED**

Probable Routes of Human Exposure:

Exposure to **toluene** diisocyanate is primarily occupational via inhalation or dermal contact with the aerosol or vapor. Workers may also be exposed through skin contact with freshly cured foam or as a result of spills or splashes. (SRC)

PEER REVIEWED

THE RESPIRATORY HEALTH OF 277 WORKERS IN A NEW **TOLUENE** DIISOCYANATE (TDI) MANUFACTURING PLANT WAS STUDIED PROSPECTIVELY DURING 5 YR OF EXPOSURE. PERSONAL TDI MONITORS WERE USED TO CONTINUOUSLY MEASURE PEAK & 8-HR TIME-WEIGHTED AVG (TWA) CONCN IN MORE THAN 2000 SAMPLES. REGRESSION OF ANNUAL CHANGE ON SMOKING (PACK-YEARS), ATOPIC STATUS & CUMULATIVE TDI EXPOSURE, DICHOTOMIZED AT 68.2 PPB MONTHS INTO LOW & HIGH EXPOSURE GROUPS, SHOWED SIGNIFICANT EFFECTS OF SMOKING ON SPIROMETRIC TESTS & LUNG VOLUMES. AFTER ADJUSTING FOR PACK-YEARS OF SMOKING, THE 74 MEN IN THE HIGH CUMULATIVE TDI EXPOSURE CATEGORY HAD SIGNIFICANTLY LARGER DECLINE IN FEV1 (1-S FORCED EXPIRATORY VOLUME), % FEV (% FORCED EXPIRATORY VOLUME) & FEF25-75% (FORCED EXPIRATORY FRACTION FROM 25 TO 75% VITAL CAPACITY) THAN DID THE 149 MEN IN THE LOW CATEGORY. ANNUAL CHANGE IN FEV1 WAS THEN EXAMINED IN 6 SMOKING-EXPOSURE CATEGORIES: IN NEVER-SMOKERS, AVG ANNUAL DECLINE WAS 38 ML/YR GREATER IN THOSE WITH HIGHER CUMULATIVE TDI EXPOSURE.

VAPORS OF THESE COMPD INVARIABLY BECOME AIRBORNE IN POLYMERIZATION REACTIONS, ESP SINCE HEAT & GAS ARE EVOLVED. /**TOLUENE** DIISOCYANATES/
[Hamilton, A., and H. L. Hardy. Industrial Toxicology. 3rd ed. Acton, Mass.: Publishing Sciences Group, Inc., 1974. 335]**PEER REVIEWED**

NIOSH (NOHS Survey 1972-1974) has statistically estimated that 29,284 workers are exposed to TDI in the USA(1). NIOSH (NOES Survey 1981-1983) has statistically estimated that 6,044 workers are exposed to TDI in the USA(2). Since the NOES survey excludes exposure to trade name chemicals which may contain the chemical, occupational exposure could be considerably higher(SRC).
[(1) NIOSH; National Occupational Health Survey (1974) (2) NIOSH; National Occupational Exposure Survey (1983)]**PEER REVIEWED**

Concentration medians for 2,4-**toluene** diisocyanate in 2 plants producing flexible polyurethane foam were 0.70 and 0.33 ppb for the mixing and finishing ends, respectively(1). The respective median values for 2,6-TDI were 0.91 and 1.1 ppb. Maximum concentrations of 2,6-TDI exceeded 64 ppb at the finishing end(1).
[(1) Rando RJ et al; Am Ind Hyg Assoc J 45: 199-203 (1984)]**PEER REVIEWED**

In a Finnish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(1). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(1). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4-isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(1). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(1). TDI levels of 1.3-2.8 ppb were detected in air inside a Swedish factory manufacturing polyurethanes(2).

[(1) Rosenberg C, Savolainen H; J Chromatography 367: 385-92 (1986) (2) Audunsson G et al; Intern J Environ Anal Chem 20: 85-100 (1985)]**PEER REVIEWED**

Mean concn ranges of TDI reported in ambient workplace air were 0.7-710 ug/cu m in TDI production, ND - 1490 ug/cu m during polyurethane foam production, 70-140 mg/cu m during elastomer production, 13 - 1050 ug/cu m during polyurethane foam use, 10-710 ug/cu m during polyurethane spray paint use, and <1-740 ug/cu m during the production of polyurethane-coated wire(1). Mean concn in personal samples ranged from ND-540 ug/cu m during polyurethane foam production and 2-1220 ug/cu m during polyurethane spray foam use(1). Additionally, mean concn of TDI released from insulation in a ship's hold was reported to be 120-150 ug/cu m and that released from coated fabric in a workplace 2-10 ug/cu m(1). During the outdoor application of TDI foam to a 40 ft diameter storage tanks, the mean atmospheric TDI concentration downwind from the spray gun was 0.3 ppm at 8 ft, 0.02 ppm at 40 ft, and 0.002 ppm at 150 ft(2). TDI was not detected more than 8 ft upwind of the spray gun(2). Air samples taken within two ft of the foam surface immediately after spraying had ceased was found to be 0.03 ppm(2). Mean TDI concentrations near the pumping equipment during material transfer was 0.02 ppm(2).

The following Overview, *** **TOLUENE** DIISOCYANATE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Toluene** diisocyanate is an irritant to skin, lungs, conjunctiva and gastrointestinal tract. Euphoria, ataxia, mental aberrations, sensitization (primarily respiratory), bronchitis, emphysema and cor pulmonale can occur.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Severe conjunctival irritation and lacrimation from liquid or high vapor concentrations is likely. Lower concentrations may produce a burning or prickling sensation.
- Glaucoma and iridocyclitis have been reported with a splash accident.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Burning or irritation of the nose and throat, cough, laryngitis, chest pain, and asthmatic syndrome (chemical bronchitis with severe bronchospasm), sensation of oppression or constriction of the chest, bronchitis, emphysema and cor pulmonale may occur.
- Respiratory symptoms may recur several years after discontinuation of exposure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute exposures may produce headache, insomnia, euphoria, ataxia, anxiety neurosis with depression, or paranoid tendencies.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Inhalation of vapor or aerosol may produce vomiting and abdominal pain. Epigastric and substernal pain may be secondary to the paroxysmal or persistent cough associated with inhalation.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Irritation and inflammation are common. Dermal absorption is low.

IMMUNOLOGIC

0.2.19.1 ACUTE EXPOSURE

- Elevated specific IgE and IgG antibodies have been detected in sensitized and exposed workers. The presence of antibodies does is an indicator of exposure

but not of sensitization.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- **Toluene** diisocynate has been classified as a 2B agent: possibly carcinogenic to humans, based on sufficient evidence of carcinogenicity in experimental animals and no human data (IARC, 1987).

0.2.21.2 HUMAN OVERVIEW

- **Toluene** diisocyanate is considered a suspected or possible human carcinogen, based on sufficient evidence of carcinogenicity or tumors (spleen, subcutaneous, hepatic, ovarian, peritoneum, mammary gland tissues) in experimental animals (IARC, 1987; US DHHS, 1994; ACGIH, 1995).

Laboratory:

- Monitor respiratory function closely.

Treatment Overview:

ORAL EXPOSURE

- Due to the irritant nature of this substance, emesis is not advised.
- DILUTION: Immediately dilute with 4 to 8 ounces (120 to 240 mL) of milk or water (not to exceed 15 mL/kg in a child).
- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- Monitor patient for respiratory distress. If a cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis and pneumonia.
- Allergic reaction: Sensitized individuals should be cautioned to avoid further exposure as serious allergic reactions may result.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- Randomized, double-blind cross-over studies showed minimal efficacy of bronchodilators. This could be due to the absence of airway hyperresponsiveness in some

TDI-induced asthma.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Available dose-response information concerning humans pertains to inhalational exposure. Concentrations of 2.5 ppm are considered Immediately Dangerous to Life or Health. A fatality in an asthmatic who continued exposure to TDI has been reported.
- The recommended short term exposure limits for TDI in industry is 0.02 ppm. TDI does not have sufficient warning properties (e.g. odor or eye irritancy) at air concentrations below the recommended short term exposure limit.

Antidote and Emergency Treatment:

Noncardiogenic pulmonary edema and bronchospasm are the most immediate serious clinical consequences of isocyanate exposure. Markedly symptomatic patients should receive oxygen, ventilatory support, and an intravenous line. Treatment for asthma includes inhaled sympathomimetics (salbutamol, metaproterenol), intravenous theophylline, parenteral sympathomimetics (epinephrine, terbutaline), and steroids. /Isocyanates/

[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 881]**PEER REVIEWED**

Copiously irrigate contaminated skin and eyes with saline. Few medical data are available to guide gut decontamination. Activated charcoal (1 g/kg) and a cathartic (sorbitol, magnesium citrate) may be useful for ingestions. /Isocyanates/

[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science

Publishing Co., Inc. 1988. 881]**PEER REVIEWED**

Most treatment is symptomatic. Mydriatics, systemic analgesics, and topical antibiotics (Sulamyd) may be used for corneal abrasions. There is no effective therapy for sensitized workers, and these people should be moved to a work site devoid of exposure to isocyanates. /Isocyanates/
[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 881]**PEER REVIEWED**

Any employee who begins to experience shortness of breath during a shift should be removed from work immediately and should not return to work until pulmonary function tests have returned to base line. As is the case with asthma of any type, pulmonary function recovery may lag behind symptom recovery and take up to eight weeks to return to normal. If sensitized, the individual should not return to work in a TDI area or work with any other isocyanate.
[Zenz, C. Occupational Medicine-Principles and Practical Applications. 2nd ed. St. Louis, MO: Mosby-Yearbook, Inc, 1988. 1020]**PEER REVIEWED**

Animal Toxicity Studies:

Evidence for Carcinogenicity:

No data are available in humans. Sufficient evidence of carcinogenicity in animals. OVERALL EVALUATION: Group 2B: The agent is possibly carcinogenic to humans.

Groups of 120 male and 120 female CD-1 mice, three to four weeks old, were exposed to 0, 0.05, or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production grade **toluene** diisocyanate (approx 80% 2,4 isomer & 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 104 wk. There was a significant reduction in body weight in the high-dose group /sex not stated/ and a significant increase in mortality in both high and low-dose females by the termination of the study. No such effect was seen in males. Neither the types of tumor observed nor their incidences were dose-related, and both corresponded to those seen in historical controls for this strain of mice. However, dose-related pathological changes were observed in the nasal cavity (chronic or necrotic rhinitis), together with changes in the lower respiratory tract (interstitial pneumonia, catarrhal bronchitis) in both groups.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 303 (1986)]**PEER REVIEWED**

Groups of 126 male and 126 female Sprague Dawley CD rats, six to nine weeks old, were exposed to 0, 0.05 or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production-grade **toluene** diisocyanate (approx 80% 2,4 isomer and 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 108 wk or 110 wk. A significant reduction in weight gain was observed during the first 12 wk of the study among the high-dose animals of each sex, but body wt gain was similar in all groups thereafter. No significant difference in mortality between treated and control groups of either sex was reported. Tumor incidences and types were reported to be similar in control and treated groups.

[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 304 (1986)]**PEER REVIEWED**

Rats receiving up to 240 mg/kg **toluene** diisocyanate by gavage daily on 5 days/wk for 13 wk were found to suffer from mild to moderate bronchopneumonia.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 306 (1986)]**PEER REVIEWED**

In dogs, a correlation has been made between immunological and respiratory responses to **toluene** diisocyanate. Dogs exposed once every second week for 41 wk to 1 mg/kg **toluene** diisocyanate delivered as an aerosol intratracheally developed a systemic immune response to **toluene** diisocyanate conjugated with dog serum albumin as well as immediate-type airway responses.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 307 (1986)]**PEER REVIEWED**

The **toluene** diisocyanate induced delayed type hypersensitivity reaction in the ear of male mice was investigated and compared with the picryl chloride induced one. The results obtained were as follows: 1) When 1% **toluene** diisocyanate solution (20 ul/ear) as a challenging concentration was used for 7 week old ICR mice, distinct ear swelling was observed in every group sensitized with various concentrations (1-5%, 100 ul/animal) of **toluene** diisocyanate solution, and the swelling rate was the same or higher than that of picryl chloride induced delayed type hypersensitivity. 2) Five, 7 and 13 week old ICR mice showed a similar high response in TDI induced delayed type hypersensitivity, whereas the reactivity of 16 week old ICR mice was significantly lower than that of the above mentioned younger mice. 3) In both **toluene** diisocyanate and picryl chloride induced delayed type hypersensitivity reaction, ICR and BALB/c mice showed a similar high response, whereas the reactivity of ddY mice was significantly lower. The effects of dexamethasone and indomethacin were investigated with the **toluene** diisocyanate induced delayed type hypersensitivity model. The delayed type hypersensitivity reaction was suppressed significantly by both drugs, but the suppressive effects of dexamethasone were higher than that of indomethacin. All the above results indicate that the **toluene** diisocyanate induced delayed type hypersensitivity model in mice taking dye leakage as an index may be useful for evaluation of drugs for disorders derived from delayed type hypersensitivity reactions.
[Tominaga M et al; Jpn J Pharmacol 39 (2): 163-71 (1985)]**PEER REVIEWED**

Exposing guinea pigs to **toluene** diisocyanate causes an acute increase in airway responsiveness to inhaled acetylcholine. The mechanism of this increase in airway responsiveness is unknown. Capsaicin-sensitive afferent nerves and the tachykinins they release upon activation are important in controlling bronchomotor tone in guinea pigs. To determine whether tachykinins are important in **toluene** diisocyanate induced airway hyperresponsiveness, the effects of tachykinin depletion were studied using capsaicin, and competitive tachykinin antagonism, using (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P, on **toluene** diisocyanate induced airway hyperresponsiveness. In 9 of 9 untreated

animals, **toluene** diisocyanate exposure caused a large and significant increase in airway responsiveness to acetylcholine. The mean concentration of acetylcholine required to decrease specific airway conductance by 50% below baseline (the PD50) was 1.51% before **toluene** diisocyanate exposure and 0.17% after **toluene** diisocyanate exposure ($p < 0.0005$). Capsaicin treatment had no effect on the PD50 but prevented the **toluene** diisocyanate induced increase in airway responsiveness in 10 of 12 animals. (The PD50 was 1.03% before **toluene** diisocyanate and 1.27% after **toluene** diisocyanate exposure.) Treatment with the tachykinin antagonist (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P also abolished the **toluene** diisocyanate induced increase in airway responsiveness in all 5 animals treated. Although **toluene** diisocyanate exposure also caused airway edema, the effect of capsaicin treatment on **toluene** diisocyanate induced hyperresponsiveness did not result from prevention of airway edema. **Toluene** diisocyanate exposure caused a marked increase in tracheal extravasation of intravenously administered Evans blue dye that was not prevented by capsaicin treatment.
[Thompson JE et al; Am Rev Respir Dis 136 (1): 43-9 (1987)]**PEER REVIEWED**

The changes in airway responsiveness to increasing doses of an acetylcholine aerosol in anesthetized and ventilated guinea pigs 2, 6, or 24 hr after exposure to air or 1 ppm **toluene** diisocyanate were examined. Pulmonary resistance after the animals inhaled a buffered saline aerosol was used as baseline and was similar for air and groups. The concentration of acetylcholine calculated to cause a 200% increase in pulmonary resistance was significantly lower for animals studied at 2 hr (0.68%) or at 6 hr (0.77%), but not at 24 hr (2.39%), after than for air animals (3.07%). The increase in airway responsiveness in the exposed animals was associated with histologic changes in the trachea and intrapulmonary airways. Exposure to 2 ppm caused a patchy loss of cilia, shedding of epithelial cells into the airway lumen, and an influx of inflammatory cells into the trachea and other airways. In the lamina propria of the trachea, the concentration of extravascular polymorphonuclear leukocytes was 13 to 26-fold greater in animals studied 2 or 6 hr after exposure to 2 ppm **toluene** diisocyanate or at 2 hr after 1 ppm **toluene** diisocyanate than in animals exposed to air. The concentration of polymorphonuclear leukocytes in the epithelium was significantly increased only in animals examined 2 hr after 2 ppm **toluene** diisocyanate. Exposure to **toluene** diisocyanate also caused an influx of eosinophils into the tracheal mucosa. This influx occurred later and was more persistent than the influx of polymorphonuclear leukocytes. These results indicate that a single exposure to **toluene** diisocyanate can cause an increase in airway responsiveness that is associated with epithelial injury and acute airwayinflammation.
[Gordon T et al; Am Rev Respir Dis 132 (5): 1106-12 (1985)]**PEER REVIEWED**

The effect of exposure to **toluene** diisocyanate vapor on pulmonary performance was studied in guinea pigs. Female English smooth haired guinea pigs were exposed to 1.4 ppm **toluene** diisocyanate vapor or air for 3 hours per day for 4 days, or to 0.02 ppm **toluene** diisocyanate for 6 hours per day for 70 days. Pulmonary performance was evaluated by the ventilatory response of the animals to 10% carbon dioxide. Serum antibodies to **toluene** diisocyanate were measured on days 22 and 50 and **toluene** diisocyanate pulmonary hypersensitivity was measured on days 37 and 38. Lung tissue histopathology was evaluated in all animals on day 50 following **toluene** diisocyanate exposure. Pulmonary response to 10% carbon dioxide diminished by 30 to 50% following **toluene** diisocyanate exposures at 1.4 ppm up to day 14. The ventilatory response showed recovery during the next 5 weeks. In contrast, animals exposed to 0.02 ppm **toluene** diisocyanate daily for 70 days showed no change in ventilatory response, nor did control animals that were not exposed to **toluene** diisocyanate. Antibodies were detected on day 22 and pulmonary

hyprsensitivity to **toluene** diisocyanate was found in all animals exposed to 1.4 ppm **toluene** diisocyanate. No antibodies to **toluene** diisocyanate nor pulmonary hypersensitivity were detected in animals exposed to 0.02 ppm **toluene** diisocyanate or in control animals. Lung tissue on day 50 in the 1.4 ppm **toluene** diisocyanate exposed animals showed multifocal subchronic interstitial inflammation, localized pleural thickening, and peripheral lymphoid hyperplasia. No apparent abnormalities were observed in lung tissue of the 0.02 ppm exposed group. Exposure to 1.4 or 0.02 ppm **toluene** diisocyanate resulted in measurable and no apparent pulmonary toxicity in guinea pigs, respectively. The 10 percent carbon dioxide challenge provide several advantages for measuring pulmonary function.
[Wang KL et al; J Toxicol Environ Health 15 (1): 137-48 (1985)]**PEER REVIEWED**

Groups of 50 F344/N rats of each sex and 50 B6C3F1 mice of each sex were gavaged with corn oil or a mixture of **toluene** diisocyanate in corn oil for 5 days per wk for 105 or 106 wk. Female rats and mice were given doses of 60 or 120 mg/kg body weight, while male rats received 30 or 60 mg/kg, and male mice received 120 or 240 mg/kg. The **toluene** diisocyanate reacted with the moisture in the corn oil vehicle resulting in doses that were 10% to 23% below the target dose concn. The chemical product used was commercial grade **toluene** diisocyanate, which was an 80%-20% mixture of the 2,4- and 2,6-isomers. Chemical disposition and metabolism studies were conducted with each of the radiolabelled **toluene** diisocyanate isomers in male rats. Absorption of both of the **toluene** diisocyanate isomers occurred, with the highest concn found in the stomach, cecum, large intestine, and bladder. Excretion occurred via the feces and urine. The major metabolic products from the metabolism of 2,4-**toluene** diisocyanate were shown to be identical with those from the metabolism of the carcinogen, 2,4-diaminotoluene, whereas the metabolism of the 2,6-**toluene** diisocyanate isomer yielded one major product, identified as 2,6-bis(acetylamino)**toluene**. Greater than 10% depression in body weight gain occurred in all dosed groups of rats throughout most of the study. The major non-neoplastic lesions that were observed in both sexes of the **toluene** diisocyanate exposed rats were dose related incr in acute broncho-pneumonia, characterized as chemical pneumonitis, with incidences as high as 50%. In mice mean body weight gain was depressed in dosed male and in high dose females. The principle non-neoplastic lesion in mice that was attributed to chemical treatment was cytomegaly of the kidney tubular epithelium in males. Survival in all groups of dosed rats was significantly lower than in controls. A dose-dependent pattern of mortality did not commence until 70 wk of exposure, demonstrating that **toluene** diisocyanate elicited a cumulative toxic response. There was also significantly lower survival in high dose male, but not female mice, by comparison to controls. Despite the reduction of power and sensitivity in the rat studies caused by early mortality, statistically significant incr in tumor incidences were observed in many different target organs. **Toluene** diisocyanate was carcinogenic in F344/N rats, causing sc fibromas and fibrosarcomas in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland tumors in females.
[Dieter MP et al; Toxicol Ind Health 6 (6): 599-621 (1990)]**PEER REVIEWED**

Toluene diisocyanate is a causative agent in occupational asthma. Through an oral catheter **toluene** diisocyanate, 0.03 ul, dissolved in 0.02 ml olive oil, was superfused on the tracheobronchial mucosa of anaesthetized guinea pigs. **Toluene** diisocyanate induced plasma exudation into both airway tissue and lumen (peak effect: 5 hr; duration approximately 17 hr). Light microscopy examinations demonstrated that the epithelium was not disrupted by this process (and that microvessels are abundant just beneath the

epithelium). At days 6 and 21 after exposure to **toluene** diisocyanate PAS-positive cells were increased, but no other histological alterations were found. Also, the occurrence of peptide containing nerve fibres was not altered by **toluene** diisocyanate. After **toluene** diisocyanate exposure the airway smooth muscle tone was elevated as examined in vitro at base-line and at conc response to carbachol. The largest incr in tone were recorded 21 days after exposure to **toluene** diisocyanate. The abnormally large tone was not associated with an increased thickness of the smooth muscle layer nor was it associated with reduced effects of either beta 2-agonist (terbutaline) or xanthine (theophylline) relaxants. It is concluded that **toluene** diisocyanate induced plasma exudation into guinea pig airways for 17 hr without disrupting the epithelial lining and without causing major changes in the airway peptidergic innervation. Both the airway tone, and the number of mucous cells, are increased for at least 3 wk after exposure to **toluene** diisocyanate.

Toluene diisocyanate was mutagenic in Salmonella typhimurium strains TA98 and TA100 in the presence (but not the absence) of Aroclor 1254-induced male Sprague Dawley rat or male Syrian hamster liver S9; it was not mutagenic in strains TA 1535 or 1537.
[DHHS/NTP; Toxicology and Carcinogenesis Studies of Commercial Grade 2,4 (80%) and 2,6 (20%) - Toluene Diisocyanate (Gavage Studies) p. 7 (1986) Technical Rpt Series No. 251 NIH Pub No. 86-2507]**PEER REVIEWED**

National Toxicology Program Studies:

Groups of 50 female F344/N rats and 50 female B6C3F1 mice were administered commercial grade **toluene** diisocyanate (80% 2,4- and 20% 2,6-) in corn oil by gavage at doses of 60 or 120 mg/kg body weight, 5 days per week for 105 or 106 weeks. Groups of 50 male F344/N rats received 30 or 60 mg/kg and groups of 50 male B6C3F1 mice received 120 or 240 mg/kg on the same schedule. Dosage analyses of **toluene** diisocyanate indicated that the chemical had reacted in the corn oil vehicle, resulting in actual gavage concentrations 77% to 90% of theoretical values. Groups of 50 rats and 50 mice of each sex received corn oil only and served as vehicle controls. Survival in all groups of dosed rats in the 2-year studies was shorter (P less than or equal to 0.005) than that of the controls; depressions in mean body weight gain relative to controls were greater than 10% in all dosed rat groups throughout most of the study. A dose-dependent pattern of cumulative toxicity began at 70 weeks and culminated in excessive mortality, indicating the estimated maximum tolerated dose had been exceeded for rats. Acute bronchopneumonia occurred at increased incidences in groups of dosed male and female rats (males: control, 2/50; low dose, 6/50; high dose, 14/50; females: 1/50, 10/50, 25/49). /Results indicated that/ commercial grade **toluene** diisocyanate in corn oil was carcinogenic for F344/N rats, causing subcutaneous fibromas and fibrosarcomas (combined) in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland fibroadenomas in females. **Toluene** diisocyanate was not carcinogenic for male B6C3F1 mice. TDI was carcinogenic for female B6C3F1 mice, causing hemangiomas or hemangiosarcomas (combined), as well as hepatocellular adenomas.

Metabolism/Pharmacokinetics:

Metabolism/Metabolites:

A technique for detectingurinary amine metabolites in rats exposed to **toluene** diisocyanate was evaluated. Skin tissue of rats was exposed to 40% **toluene**-2,4-diisocyanate solution in di-n-butyl-ether liquid. Rats were exposed daily for 3 hr on 4 consecutive days. Urine was collected in metabolic cages for 18 hr after the last exposure. Chromatographic techniques were used for nitrogen selective detection of nonderivatized amines. An autolinear temperature programmer was employed to analyze derivatized amine. The identity of the amine was confirmed by gas chromatography/mass spectrometry. A linear correlation was found between **toluene**-2,4-diamine added to urine and peak height. Peak height and recovery from the non hydrolyzed and from the hydrolyzed urine was about 85 and 70%, respectively. No free **toluene**-2,4-diamine or free **toluene**-2,4-diisocyanate was detected in the urine of rats exposed to **toluene**-2,4-diamine in hydrolyzed urine was 1.5 micrograms per milliliter. Gas chromatography/mass spectrometry confirmed the identity of the amine. /This/ highly sensitive technique tested is easy to apply

and is effective for trace assays of amines.
[Rosenberg C; J Chromatography 323 (2): 429-33 (1985)]**PEER REVIEWED**

Epithelial injury and inflammation are involved in airway hyperresponsiveness and asthma induced by **toluene** diisocyanate. In that isocyanates are insoluble and highly reactive compounds, bronchial epithelial cells may represent the most important target cells of their toxic effect. We hypothesized that damage to airway epithelium by **toluene** diisocyanate may result in the release of metabolites of arachidonic acid, which are known to promote inflammation and to alter epithelial cell function and airway smooth muscle responsiveness. To test this hypothesis we examined eicosanoid products in the culture media of bronchial epithelial cells exposed in vitro to 8 and 18 ppb **toluene** diisocyanate. Epithelial cells derived from human bronchi obtained at surgery were cultured to confluency on collagen-coated microporous membranes. Those cells, which expressed differentiated characteristics of epithelial cells (they showed keratin-containing filaments and had a cobblestone appearance), were alternatively exposed to **toluene** diisocyanate or air for 30 min in a specially designed in vitro chamber. The production of metabolites of arachidonic acid was assessed by measuring the release of immunoreactive products into the cell medium at the end of the exposure and during a 2 hr period after exposure. This method revealed a predominant isocyanate induced release of immunoreactive 15-hydroxyeicosatetraenoic acid. Release rate of this compound tended to be dose-related and was associated with cell damage as assessed by the release of lactate dehydrogenase in the medium.
[Mattoli S et al; J Cell Physiol 142 (2): 379-85 (1990)]**PEER REVIEWED**

It has been previously shown that tachykinin depletion or antagonism prevented the increase in airway responsiveness to inhaled acetylcholine caused by exposure to **toluene** diisocyanate in awake guinea pigs. To insure that the effects of tachykinins were not limited to the extrathoracic airways and were not dependent on effects of **toluene** diisocyanate on baseline airway caliber, airway responsiveness to acetylcholine inhaled through tracheostomy in anesthetized and ventilated guinea pigs that were exposed to **toluene** diisocyanate or air after treatment with the tachykinin antagonist spantide, the tachykinin metabolism inhibitor phosphoramidon, or the vehicles for each drug were determined. When these drugs were administered before and during **toluene** diisocyanate exposure, spantide significantly inhibited the **toluene** diisocyanate induced increase in acetylcholine responsiveness and phosphoramidon significantly potentiated this effect, whereas neither drug altered acetylcholine responsiveness in air exposed animals. To determine whether tachykinins were exerting their effect primarily during **toluene** diisocyanate exposure or during the subsequent acetylcholine challenge, the effect of each drug on acetylcholine responsiveness was also examined when the drugs were given after **toluene** diisocyanate exposure. At that time, spantide did not inhibit **toluene** diisocyanate induced acetylcholine hyperresponsiveness and phosphoramidon did not potentiate it. Neither drug nor **toluene** diisocyanate increased pulmonary resistance measured through a tracheostomy in these anesthetized and ventilated animals. These results suggest that the **toluene** diisocyanate induced increase in acetylcholine responsiveness is mediated by release of tachykinins into the intrathoracic airways during exposure to **toluene** diisocyanate.
[Sheppard D, Scypinski L; Am Rev Respir Dis 138 (3): 547-51 (1988)]**PEER REVIEWED**

Five men were exposed to **toluene** diisocyanate atmospheres for 7.5 hr. The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8 cu m stainless steel test chamber. The mean air concn of **toluene** diisocyanate was ca 40 ug/cu m,

which corresponds to the TLV of Sweden. The inhaled doses of 2,4- and 2,6-**toluene** diisocyanate were ca 120 ug. **Toluene** diisocyanate in the test chamber air was determined by an HPLC method using the 9-(N-methylaminomethyl)-anthracene reagent and by a continuous monitoring filter-tape instrument. After hydrolysis of plasma and urine, the related amines, 2,4- and 2,6-toluenediamine 2,4-, and 2,6-TDA), were determined as pentafluoropropionic anhydride derivatives by capillary gas-chromatography using selected ion monitoring in the electron-impact mode. The urinary elimination of the toluenediamines showed a possible biphasic pattern, with rapid first phases for 2,4-toluenediamine (mean half-life for the concn in urine, 1.9 hr) and for 2,6-toluenediamine (mean half-life for the concn in urine, 1.6 hr). The cumulative amount of 2,4-toluenediamine excreted in urine within 28 hr ranged from 8% to 14% of the estimated dose of 2,4-**toluene** diisocyanate, and the cumulative amount of 2,6-toluenediamine in urine ranged from 14% to 18% of the 2,6-**toluene** diisocyanate dose. The average urinary level of 2,4-toluenediamine was 5 ug/l in the 6 to 8 hr sample (range 2.8-9.6 ug/l), and the corresponding value fo 2,6-toluenediamine was 8.6 ug/l (range, 5.6-16.6 ug/l). Biological monitoring of exposure to 2,4- and 2,6-**toluene** diisocyanate by analysis of 2,4- and 2,6-toluenediamine in urine is feasible.

Mechanism of Action:

SERUM FROM 26 PERSONS SHOWN TO REACT TO PROVOCATIVE INHALATION CHALLENGE WITH LOW CONCN OF **TOLUENE** DIISOCYANATE WAS TESTED BY RADIOALLERGOSORBENT TEST (RAST) USING A P-TOLYL ISOCYANATE-HUMAN SERUM ALBUMIN (TMI-HSA) CONJUGATE. POSITIVE RESULTS WERE OBTAINED IN 15-19% OF **TOLUENE** DIISOCYANATE REACTORS, DEPENDING ON THE METHOD OF EVALUTION. **TOLUENE** DIISOCYANATE ASTHMA MAY BE A COMPLEX SYNDROME WITH SEVERAL TYPES OF REACTIONS POSSIBLE, INCLUDING AN IMMUNOGLOBULIN-E MECHANISM IN SOME INDIVIDUALS. THE THEORY THAT **TOLUENE** DIISOCYANATE ASTHMA IS BASED SOLELY ON AN IMMUNE MECHANISM IS NOT SUPPORTED. THE FINDINGS DO NOT DISAGREE WITH THE HYPOTHESIS THAT **TOLUENE** DIISOCYANATE REACTIVITY MAY BE MEDIATED BY A PHARMACOLOGIC MECHANISM.
[BUTCHER BT ET AL; J ALLERGY CLIN IMMUNOL 66 (3): 213 (1980)]**PEER REVIEWED**

To investigate the role of pharmacological mechanisms in **toluene** diisocyanate induced occupational asthma, the effects of **toluene** diisocyanate on rat trachea ring and lung parenchymal strip were studied in vitro. The most prominent effect observed was a stimulation of metacholine induced contraction of the tracheal ring by 1M **toluene** diisocyanate (added in dimethyl sulfoxide). The results were less pronounced when **toluene** diisocyanate was added from a stock solution prepared in water, which is possibly due to copolymerisation. It is concluded that the pharmacological effect of **toluene** diisocyanate may result from an autonomic imbalance between cholinergic and B-adrenergic neural control.
[Borm PJA et al; Br J Ind Med 46 (1): 56-9 (1989)]**PEER REVIEWED**

A study of the occurrence of serum immunoglobulin-E and immunoglobulin-G antibodies in workers with isocyanate induced asthma was conducted. The study group consisted of 62 workers (58 males) being evaluated for occupational asthma. Thirty nine had been exposed to hexamethylene diisocyanate, 17 to diphenylmethane diisocyanate, and six to **toluene** diisocyanate. The subjects completed a

respiratory and occupational questionnaire. Spirometric tests were administered. Skin prick tests were performed with 15 common inhalant allergens and **toluene** diisocyanate, hexamethylene diisocyanate, and diphenylmethane diisocyanate human serum albumin conjugates. Blood samples were collected and assayed for specific serum immunoglobulin-G and immunoglobulin-E antibodies to hexamethylene diisocyanate, diphenylmethan diisocyanate, and **toluene** diisocyanate. Specific inhalation challenges were conducted with hexamethylene diisocyanate, diphenylmethane diisocyanate, and **toluene** diisocyanate. Specific inhalation challenge with **toluene** diisocyanate, hexamethylene diisocyanate, or diphenylmethane diisocyanate induced significant bronchoconstriction in half of the subjects, late reactions being the most common. Twenty subjects had significantly elevated immunoglobulin-G concn and nine had significantly elevated immunoglobulin-G plus immunoglobulin-E concn. Six of 12 subjects with elevated immunoglobulin-E and immunoglobulin-G antibodies had positive skin prick tests for hexamethylene diisocyanate and one was sensitized to diphenylmethane diisocyanate. It was concluded that an association between isocyanate specific antibodies and the results of specific inhalation challenge tests has been established. This suggests that isocyanate induced asthma may involve an immunological mechanism.
[Cartier A et al; J Allergy Clin Immunol 84 (4 Part 1): 507-14 (1989)]**PEER REVIEWED**

The influence of cyclophosphamide induced granulocyte depletion on **toluene** diisocyanate related changes in airway reactivity and pathology was assessed in guinea pigs. Twelve cyclophosphamide-treated and 12 control animals comprising each group were studied physiologically before and 2 hr after a single 10 min exposure to 3 ppm of **toluene** diisocyanate. Reactivity was determined in intact unanesthetized animals by measuring specific airway conductance before and during intravenous acetylcholine infusion. After testing, tracheal tissue for light microscopic examination was obtained from three hyperreactive guinea pigs in each exposed group and compared with tissue from treated and control animals (n = 3 each) that had not been **toluene** diisocyanate exposed. Cyclophosphamide treatment caused substantial decr in both circulating and airway granulocyte counts. However, the incidence and degree of bronchial hyperreactivity that occurred 2 hr post-**toluene** diisocyanate was similar in the untreated and treated groups. Results indicate that **toluene** diisocyanate induced bronchial hyperreactivity 1) occurs shortly after a brief high concn exposure and 2) appears independent of circulating or airway granulocyte counts.
[Cibulas W Jr et al; J Appl Physiol 64 (5): 1773-8 (1988)]**PEER REVIEWED**

To determine the importance of airway inflammation for the development of late asthmatic reactions, we examined sensitized subjects during late asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. Late asthmatic reactions are associated with a transient increase of bronchial responsiveness and, at the same time, with an increase of neutrophils followed by eosinophils, and of leukotriene B4 and albumin in bronchoalveolar lavage fluid. Late asthmatic reactions, increased bronchial responsiveness, and increase of neutrophils, eosinophils, leukotriene B4, and albumin concn in bronchoalveolar lavage induced by exposure to **toluene** diisocyanate are all prevented by pretreatment with prednisone but not with the nonsteroidal anti-inflammatory agent indomethacin. Aerosolized steroids (beclomethasone and dexamethasone isonicotinate) completely inhibit late asthmatic reactions induced by **toluene** diisocyanate, whereas theophylline has a partial, and verapamil, ketotifen, and cromolyn have no protective effect. These results suggest that late asthmatic reactions induced by **toluene** diisocyanate may be caused by airway inflammation, and that anti-inflammatory steroids should

be recommended in the prophylaxis of **toluene** diisocyanate asthma.
[Fabbri LM et al; Am Rev Respir Dis 143 (3 Pt 2): 537-8 (1991)]**PEER REVIEWED**

The effects of **toluene** diisocyanate on T-cell subpopulations and circulating lymphocytes in ten persons (five males)): 19 to 50 yr old, with **toluene** diisocyanate induced occupational asthma were examined. Five subjects revealed early and late asthmatic reactions to **toluene** diisocyanate (dual responders) and five revealed late asthmatic reactions (late responders). Subjects underwent inhalation challenge with 0.005 to 0.015 ppm **toluene** diisocyanate or filtered air for 10 to 30 min on two occasions. One second forced expiratory volumes were measured before and at periodic intervals between 30 min and 24 hr after challenge. Venous blood samples were drawn 30 min and 8, 24, 48, and 72 hr after **toluene** diisocyanate. Total and differential leukocyte counts and T-cell subpopulations were determined. The five dual responders demonstrated forced expiratory volume in 1 sec decreased indicative of early and late asthmatic reactions and the five late responders demonstrated forced expiratory volume in 1 second decr indicative of a late asthmatic reaction. **Toluene** diisocyanate challenge did not affect the number of circulating erythrocytes and leukocytes. The percentage of eosinophils was significantly increased 24 hr after challenge and sustained for up to 48 hr. The percentages of neutrophils, lymphocytes, and monocytes were not altered by **toluene** diisocyanate. Among the T-lymphocyte subpopulation, the proportion of CD8(+) lymphocytes was significantly increased 8 hr after **toluene** diisocyanate challenge. The increase was more pronounced in the lat responders. An additional increase in CD8(+) lymphocytes occurred 48 hr post exposure in seven subjects but was unrelated to responder type. The number of CD4(+) cells did not change. This resulted in a decrease in the CD4(+)/CD8(+) ratio 8 and 48 hr after **toluene** diisocyanate challenge. It was concluded that **toluene** diisocyanate induced late asthmatic reactions are associated with an increase in the number of suppressor/cytotoxic lymphocytes and eosinophils in peripheral blood.
[Finotto S et al; Br J Ind Med 48 (2):116-21 (1991)]**PEER REVIEWED**

Intravenously administered endotoxin inhibits the polymorphonuclear leukocyte dependent airway edema produced in guinea pigs exposed to **toluene** diisocyanate. Tumor necrosis factor is produced in vivo by peripheral blood monocytes and tissue macrophages stimulated with endotoxin and has been shown to activate polymorphonuclear leukocyte's and vascular endothelial cells. To determine whether the inhibition of airway edema is mediated by tumor necrosis factor, guinea pigs were treated with intravenous saline or 75,000 U/kg recombinant human tumor necrosis factor 1.5 hr before exposure to air or 3 ppm **toluene** diisocyanate for 1 hr. Animals were then injected intravenously with 50 mg/kg Evans blue dye as a marker of protein extravasation. Saline-treated animals exposed to **toluene** diisocyanate had a significant increase in tracheal Evans blue dye extravasation (85 + or - 6.5 ug dye/g trachea, mean + or - standard error) compared with saline-treated animals exposed to air (31.3 + or - 2.5, $P < 0.001$). The tracheal extravasation of Evans blue dye was significantly inhibited ($P < 0.05$) in **toluene** diisocyanate exposed animals treated with tumor necrosis factor (64.7 + or - 7.5). Neither heat-inactivated tumor necrosis factor (104.9 + or - 9.5) nor tumor necrosis factor neutralized with a monoclonal antibody against tumor necrosis factor (99.7 + or - 17.9) inhibited **toluene** diisocyanate induced airway edema. In addition, treatment with 15,000 U/kg (99.9 + or - 21.3) or 150,000 U/kg (103.2 + or - 17.6) interleukin 1, a monokine also produced in response to endotoxin, did not prevent airway edema. These results suggest that tumor necrosis factor released in response to endotoxin mediates endotoxin's inhibition of a polymorphonuclear leukocyte dependent airway edema.

Serum immunoglobulin-G and immunoglobulin-E to isocyanate haptenized human serum albumin (HSA) were estimated by ELISA in 55 isocyanate workers who underwent isocyanate inhalation challenge studies in Montreal, Canada. The challenges were negative in 29 workers and positive in 26 workers. Isocyanate antibodies were estimated by ELISA index. The mean immunoglobulin-G indices were found to be significantly higher in the challenge-positive workers, and there was a similar trend for the immunoglobulin-E indices. Antibody specificities for **toluene** diisocyanate-human serum albumin, diphenylmethane diisocyanate-human serum albumin, and hexamethylene diisocyanate-human serum albumin were determined by inhibition studies with a variety of isocyanate haptenized carriers. The other isocyanate substituted carriers were either noninhibitory or caused only partial inhibition as contrasted with the complete inhibition achieved by human serum albumin conjugated to the isocyanate to which the worker was exposed. We interpret these specificity studies as indicating that the inhalation of isocyanates results in production of antibody that recognizes new antigenic determinants that develop from the coupling of isocyanates to homologous proteins.

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concn ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concn of tolyl group after 72 hr and persists at a nanomolar level even 2 wk following the exposure. The initial rate of (14)C uptake is also a linear function of the concn of **toluene** diisocyanate when expressed either as concn (ppm) or as concn multiplied by duration of exposure (ppm.hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm.hr. Finally, the inclusion of the data on methyl isocyanate indicates that the uptake into arterial blood is a function of exposure concn, independent of isocyanate structure.

Isocyanates are an important cause of occupational asthma. The mechanism of isocyanate induced asthma is still unknown. To determine whether **toluene** diisocyanate stimulates the 'efferent' function of peripheral endings of capsaicin-sensitive sensory nerves, we investigated the effect of **toluene** diisocyanate in the rat isolated urinary bladder, a preparation in which the action of capsaicin has been well characterized. **Toluene** diisocyanate (0.03 mM) produced a concn dependent contraction of the bladder strips. It maximal effect was about 50 % of the response to capsaicin (1 uM). Previous exposure of the strips to capsaicin followed by washing out produced complete unresponsiveness, both to the first exposure to **toluene** diisocyanate and to a second exposure of capsaicin. Further, the response to both **toluene** diisocyanate and capsaicin was completely prevented by extrinsic bladder denervation, achieved by bilateral removal of pelvic ganglia (72 hr before). Repeated exposure of the rat bladder to **toluene** diisocyanate reduced the capsaicin-evoked release of calcitonin gene-related peptide like immunoreactivity (CGRP-LI), taken as biochemical marker of activation of these sensory nerves. These experiments provide the first evidence that **toluene** diisocyanate activates directly or indirectly the efferent function of capsaicin-sensitive primary sensory nerves.

The in vivo exposure to an asthmogenic stimulus, **toluene** diisocyanate, causes airway epithelial damage associated with inflammation and increased bronchial hyperresponsiveness. The latter mechanisms might partly be mediated by the release of eicosanoids from bronchial epithelial cells. Previously it has been demonstrated that the in vitro exposure of bronchial epithelial cells to **toluene** diisocyanate results in the release of immunoreactive 15-hydroxyeicosatetraenoic acid, a product of activation of the 15-lipoxygenase pathway with inflammatory properties. Present study shows that **toluene** diisocyanate induced release of 15-hydroxyeicosatetraenoic acid from epithelial cells can be prevented by nedocromil sodium, an anti-asthmatic drug with anti-inflammatory properties. This mode of action of the compound may explain its clinical effectiveness in asthma.

[Mattoli S et al; Int Arch Allergy Appl Immunol 92 (1): 16-22 (1990)]**PEER REVIEWED**

To determine whether early and/or late asthmatic responses induced by **toluene** diisocyanate are caused by a reflex mechanism involving stimulation of muscarinic receptors, we studied the effect of the muscarinic antagonist atropine on early and late airway response induced by **toluene** diisocyanate. A preliminary study was conducted in asthmatics to assess whether the selected dose of atropine provided adequate muscarinic blockade. On different days we measured the provocation dose (in mg) of carbachol causing a 15% decrease in forced expiratory volume in 1 second (PD15FEV1) without and with atropine premedication (0.008 or 0.012 mg/kg sc atropine 30 or 90 min before carbachol challenge test). 0.008 to 0.012 mg/kg sc atropine increased the PD15FEV1 carbachol by 6 to 10 fold, inducing a consistent and prolonged decrease in nonspecific bronchial hyperresponsiveness to cholinergic agent. 10 Subjects with a history of sensitization to **toluene** diisocyanate were then examined in 2 sets of experiments. In the first set of experiments, the subjects were studied before and after exposure to **toluene** diisocyanate (0.04 ppm; 30 min) after no treatment. In the second set of experiments, carried out 1 to 2 wk later, the same procedure was repeated after treatment with atropine (0.008 to 0.012 mg/kg atropine sulfate administered sc 30 min before **toluene** diisocyanate challenge, and then at 90 min intervals after **toluene** diisocyanate exposure); all patients showed symptoms of atropine effect (dryness of mouth, cycloplegia, increased heart rate).

Light and electron microscopic structure of lobar bronchial biopsies were examined of nine subjects with occupational asthma induced by **toluene** diisocyanate and of four control nonasthmatic subjects who had never been exposed to **toluene** diisocyanate. Inflammatory cell numbers were separately assessed in the intact epithelium, in the more superficial layer of the submucosa, and in the total submucosa. Asthmatic subjects had an increased number of inflammatory cells in the airway mucosa compared with control subjects. Eosinophils were significantly increased in all compartments, CD45-positive cells were significantly increased in the epithelium and in the more superficial layer of the submucosa, and mast cells were significantly increased only in epithelium. By electron microscopy eosinophils and mast cells appeare degranulated only in asthmatic patients. In the areas of epithelium that appeared intact by light microscopy, electron microscopy showed that, although the intercellular spaces between columnar cells were similar in asthmatic and control groups, the intercellular spaces between basal cells were significantly wider in patients with asthma. Patients with **toluene** diisocyanate induced asthma also had a thicker subepithelial reticular layer, where immunohistochemistry showed the presence of collagen III. In

conclusion, in patients with asthma induced by **toluene** diisocyanate, the airway mucosa shows pathologic features, such as inflammatory cell infiltrate and thickening of subepithelial collagen, similar to those described in atopic asthma.

Serum neutrophil chemotactic activity, which is associated with mast cell or basophil activation, was quantitated to determine if mast cell or basophil mediators are released during bronchoprovocation-inhalation challenge with subirritant levels of **toluene** diisocyanate. Four subjects with suspected **toluene** diisocyanate induced asthma and four mite-sensitive subjects with asthma who served as a comparison group were studied. neutrophil chemotactic activity was measured in a multiwell, microchemotaxis chamber. Blood samples were collected, and forced expiratory volume in 1 second measurements were performed before challenge and at regular intervals during the subsequent 24 hr. Three of four workers clinically sensitive to **toluene** diisocyanate reacted to a subirritant **toluene** diisocyanate exposure. There was no increase in neutrophil chemotactic activity during placebo challenges. neutrophil chemotactic activity increased in the three **toluene** diisocyanate sensitive workers during early and late asthmatic reactions in quantities proportional to the forced expiratory volume in 1 second decline. No increase in neutrophil chemotactic activity was found during **toluene** diisocyanate exposures in the **toluene** diisocyanate negative worker. Gel filtration analysis demonstrated the main neutrophil chemotactic activity fraction eluted with macromolecules of an estimated molecular weight greater than 440,000 daltons. This characteristic is compatible with neutrophil chemotactic factor of basophil or mast cell origin. The kinetics of neutrophil chemotactic activity release were similar in mite- and **toluene** diisocyanate induced asthmatic reactions. A high correlation ($r = 0.97$; $p = 0.0006$) was obtained between the percent decrease in forced expiratory volume in 1 second during early asthmatic reactions and percent increase in neutrophil chemotactic activity. These observations support the hypothesis that activation of mast cells or basophils is associated with **toluene** diisocyanate induced early and late asthmatic reaction.
[Sastre J et al; J Allergy Clin Immunol 85 (3): 567-72 (1990)]**PEER REVIEWED**

In order to determine whether treatment with ketotifen inhibits asthmatic reactions induced by **toluene** di-isocyanate, six sensitized subjects with previously demonstrated dual or late asthmatic reaction after inhalation challenge with **toluene** diisocyanate were studied. Ketotifen (1 mg bid, orally) or placebo was administered for 7 days to the examined subjects, according to a double-blind, cross-over, placebo controlled study design. When the subjects were treated with either ketotifen or placebo, forced expiratory volume in 1 second markedly decr after exposure to **toluene** diisocyanate. These results suggest that the anti-asthmatic agent ketotifen is not effective in **toluene** diisocyanate induced asthma and suggest that it should not be used in the prophylaxis of asthmatic reactions induced by **toluene** diisocyanate in sensitized subjects.
[Tossin L et al; Clin Exp Allergy 19 (2): 177-82 (1989)]**PEER REVIEWED**

The beta-adrenoceptors on intact peripheral blood lymphocytes were studied in 21 allergic asthmatics, 11 **toluene** diisocyanate asthmatics and 17 normal subjects with radioligand binding assay technique. The airway responsiveness to methacholine provocation test was determined. The results indicated that beta-adrenoceptor Bmax values in allergic and **toluene** diisocyanate asthmatics were reduced but the affinity between receptor and ligand was increased; there was a positive correlation between the values

of Bmax and forced expiratory volume in 1 second%, V25/Pr in both asthmatic groups, a positive correlation between the values of Bmax and PC20 in allergic asthmatics. The beta-adrenoceptor responsiveness was remarkably reduced in allergic asthmatics.

Leukotriene B4 release from the lungs of sensitized subjects during asthmatic reactions induced by **toluene** diisocyanate was investigated. Three groups of **toluene** diisocyanate sensitized subjects were examined, one after no exposure to **toluene** diisocyanate, the second 8 hr after an exposure to **toluene** diisocyanate that caused an early asthmatic reaction, and the third 8 hr after an exposure to **toluene** diisocyanate that caused a late asthmatic reaction. Bronchoalveolar lavage fluid was analysed by reverse-phase HPLC and by specific radioimmunoassay. The mean concn of leukotriene B4 was higher (0.31 + or - 0.09 (standard error) ng/ml, range 0.15-0.51) in bronchoalveolar lavage fluid of sensitized subjects who developed a late asthmatic reaction than in bronchoalveolar lavage fluid of subjects who developed an early asthmatic reaction (0.05 + or - 0.04 ng/ml, range 0-0.224), and no leukotriene B4 was detectable in the control subjects. Bronchoalveolar lavage was also performed 8 hr after **toluene** diisocyanate exposure on four **toluene** diisocyanate sensitized late-dual reactors who were on steroid treatment. In this group of subjects no leukotriene B4 was detectable. These results suggest that leukotriene B4 may be involved in late asthmatic reactions induced by **toluene** diisocyanate.

Interactions:

The effects of methacholine inhalation on airway responsiveness in **toluene** diisocyanate induced asthma were studied in six workers with a history of sensitivity to **toluene** diisocyanate. Symptoms among subjects included shortness of breath, wheezing, cough, and chest tightness at work, during the evening, or at night. A detailed cllnical and occupational history was taken for each subject, and lung function measurement and skin intradermal tests for common allergens were conducted. Airway responsiveness to methacholine was assessed before subjects were exposed for 30 minutes to 0.02 part per million **toluene** diisocyanate in an exposure chamber. Eight hours after **toluene** diisocyanate inhalation, airway responsiveness to methacholine was again determined. Forced expiratory volume was the measure of airway responsiveness. Although methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, the challenge went into the asthmatic range after **toluene** diisocyanate inhalation. Airway responsiveness increased significantly 8 hours after **toluene** diisocyanate challenge in the subjects and was accompanied by a decrease in forced expiratory volume. The late asthmatic reaction began between 3 and 5 hours asthma can be induced by **toluene** diisocyanate in the absence of airway responsiveness.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Commercial **toluene** diisocyanate (TDI) is composed of 2 isomers. 2,4-**Toluene** diisocyanate constitutes roughly 80% of TDI, the other 20% being the 2,6-isomer. It may be released to the environment as fugitive emissions and from stack exhaust during the production, transport, and use of TDI in the manufacture of polyurethane foam products and coatings as well as from spills. The types of reactions which the isomers undergo are similar, although the rates may differ. The reactivity of the 2,4-**toluene** diisocyanate with active hydrogen is greater than with the 2,6-isomer, therefore the percentage of 2,4-**toluene** diisocyanate in monitored TDI is generally much less than the 80% in the commercial mixture. However, since much of the monitoring data do not distinguish between isomers, it is not possible to know the proportion of the isomers in the TDI. If spilled on wet land, TDI is rapidly degraded. In one experiment simulating a spill, 5.5% of the original material remained after 24 hours and in a field situation, the concentration of TDI had declined to the ppm levels in 12 weeks. If released into water, a crust forms around the liquid TDI and <0.5% of the original material remains after 35 days. Low concentrations of TDI disappear from the aqueous environment in approximately a day. In the atmosphere, TDI reacts with photochemically produced hydroxyl radicals (half-life 3.3 hr) and is also removed by dry deposition. Human exposure is primarily occupational via inhalation and dermal contact. (SRC)

Environmental Fate:

TERRESTRIAL FATE: Ten days after a spill of 13 tons of **toluene** diisocyanate (TDI) onto swampy, wet forest soil, TDI and toluenediamines were found in the soil(1,2). The TDI solidified and the area was covered with sand. The soil concn of TDI and toluenediamine combined declined from the parts per thousand to parts per million range between 10 days and 12 wk after the spill(2). No TDI was detected in

a connecting brook 10 days after the spill(2). After 6 years only TDI-derived polyureas were found at the site(1). In a simulated spill, 5 kg of TDI in a container was covered with 50 kg of sand and 5 kg of water at ambient temperatures and samples taken from the top and bottom of the sand pile. After 24 hr, 5.5% of the TDI remained unreacted and after 8 days 3.5% remained(2). The reaction product was largely polyureas(2).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985) (2) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-7 (1984)]**PEER REVIEWED**

AQUATIC FATE: When low concns of TDI are released into model river or seaway systems, it is hydrolyzed within a day. In order to simulate a spill of TDI in stagnant water, 0.5 liters of TDI was poured into 20 liters of water of pH 5, 7, or 9 at 20 deg C. A hard compact crust formed at the water TDI interface(1). This crust thickened over a period of 30 days until no liquid TDI remained. The solid crust contained <0.5% of the original TDI after 35 days(1). Another experiment were performed to simulate a spill into running water by pouring 0.5 l of TDI into 20 l of slowly overflowing water. Barely detectable amounts of toluenediamine were present in the overflow samples. As in the stagant water simulation, a crust formed that contained <0.5% of the original TDI after 35 days(1).
[(1) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-17 (1984)]**PEER REVIEWED**

ATMOSPHERIC FATE: Removal of TDI from the atmosphere is due to reaction with photochemically produced hydroxyl radicals (half-life 3.3 hr) as well as through dry deposition. Earlier ideas that reaction with water vapor was of major importance have not been substantiated in recent experiments.(SRC)
PEER REVIEWED

Environmental Biodegradation:

Toluene diisocyanates are expected to be hydrolyzed much more rapidly than they are attacked by microorganisms. The resulting **toluene** diamines are subject to a wide variety of biochemical transformations.
[ITC/USEPA; Information Review #231 (Draft) Toluene Diisocyanates p. 19 (1981)]**PEER REVIEWED**

Environmental Abiotic Degradation:

Toluene diisocyanate reacts readily with compounds containing active hydrogens, such as water, acids, and alcohols(2). Contact with bases may cause uncontrollable polymerization with rapid evolution of heat(2). In concentrated solutions, hydrolysis of one of the isocyanate groups to the amine is followed by rapid reaction of the amine with an isocyanate group on another molecule leading to dimers, oligimers, and polymers(2). In one experiment the hydrolysis product yield was 20% diamine and 80% polyurea(3). When 50 ppm of **toluene** diisocyanate was added to model river and seawater systems, the concn fell to 0.1 ppm or less at the end of 1 day(1).

Gas phase loss of TDI was originally thought to be due to reaction of TDI with water vapor. One early work showed that the percent disappearance of TDI in air depended almost solely on the water vapor concentration, increasing 3.2% per unit increase in absolute humidity (g water/kg dry air), so that at 15 g water/kg dry air, a 50% reduction in TDI was obtained(2). These reductions were obtained after 8 sec and did not differ appreciably after 75 sec(2). More recent work contradicted these earlier findings and a program was instituted to study the gas-phase reactions between TDI and water using a room sized environmental chamber(1). They found that over a relative humidity range of 7-70%, the loss rate of TDI was independent of humidity and no toluenediamine or TDI-urea products could be detected(1). No evidence of gas phase reaction between water and TDI could be detected. The loss of TDI was due to adsorption to the chamber walls(1).
[(1) Holdren MW et al; Am Ind Hyg Assoc J 45: 626-33 (1984) (2) Dyson WL, Hermann ER; Amer Ind Hyg Assoc J 32: 741-4 (1971)]**PEER REVIEWED**

Subsequent experiments were performed in the environmental chamber to assess the importance of photolysis, reaction with free radicals, and adsorption onto particulate matter as atmospheric removal processes(1). The loss rate of TDI in irradiated clean air was first order with a half-life of 3.3 hr(1). By using a free radical scavenger, it was shown that free-radicals and not photolysis was responsible for the removal. The half-life is consistant with the reaction with photochemically generated hydroxyl radicals(1). The addition of a urban surrogate hydrocarbon mixture (polluted urban air), did not significantly alter removal rates(1). The concentration of hydroxyl radicals generally increases in polluted air resulting in shorter half-lives which were not observed in the above study(SRC). Adsorption to particulate matter was not significant(1).
[(1) Duff PB; Proc of the SPI Tech/Mark Conf 29: 9-14 (1985)]**PEER REVIEWED**

Volatilization from Water/Soil:

The vapor pressure of TDI is 0.01 torr at 20 deg C(1), and therefore spilled TDI will not readily volatilize from soil surfaces or other surfaces(SRC). Since TDI reacts with water, volatilization from water should not be important(SRC).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985)]**PEER REVIEWED**

Environmental Water Concentrations:

Toluene diisocyanate has been reported in the waste-water of a furniture manufacturing area in a concn range of 0.1-4.1 mg/l.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

Effluent Concentrations:

TDI has been reported in waste water from furniture manufacturing in the concn range of 0.1-4.1 ppm(1). However the coloremetric method used did not distinguish between the disocyanate or the corresponding amine(1). In view of TDI's rapid reactivity with water, it is probable that the chemical detected was the

corresponding amine(SRC). Stack exhaust from a polyurethane foam production plant were reported to contain 100-17,700 ug/cu m of TDI(1).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985)]**PEER REVIEWED**

Sediment/Soil Concentrations:

Ten days after an accident resulting in the spillage of 13 tons of **toluene** diisocyanate from a lorry on a swampy wet forest area, **toluene** diisocyanate and toluenediamine were /found/ in the soil. After six yr, only **toluene** diisocyanate-derived polyureas were found in soil samples taken at the same site.

Environmental Standards & Regulations:

TSCA Requirements:

Pursuant to section 8(d) of TSCA, EPA promulgated a model Health and Safety Data Reporting Rule. The section 8(d) model rule requires manufacturers, importers, and processors of listed chemical substances and mixtures to submit to EPA copies and lists of unpublished health and safety studies. Benzene, 1,3-diisocyanatomethyl- is included on this list.
[40 CFR 716.120 (7/1/91)]**PEER REVIEWED**

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 100 lb or 45.4 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/91)]**PEER REVIEWED**

RCRA Requirements:

U223; As stipulated in 40 CFR 261.33, when **toluene** diisocyanate, as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).

[40 CFR 261.33 (7/1/91)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Toluene** diisocyanate is produced, as an intermediate or a final product, by process units covered under this subpart.

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Combustible material: may burn but does not ignite readily. Substance will react with water (some violently) releasing flammable, toxic or corrosive gases and runoff. When heated, vapors may form explosive mixtures with air: indoors, outdoors, and sewers explosion hazards. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapors may travel to source of ignition and flash back. Contact with metals may evolve flammable hydrogen gas. Containers may explode when heated or if contaminated with water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Health: TOXIC; inhalation, ingestion or contact (skin, eyes) with vapors, dusts or substance may cause severe injury, burns, or death. Reaction with water or moist air will release toxic, corrosive or flammable gases. Reaction with water may generate much heat which will increase the concentration of fumes in the air. Fire will produce irritating, corrosive and/or toxic gases. Runoff from fire control or dilution water may be corrosive and/or toxic and cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-156]**QC REVIEWED**

Fire: Note: Most foams will react with the material and release corrosive/toxic gases. Small fires: CO2, dry chemical, dry sand, alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. FOR CHLOROSILANES, DO NOT USE WATER; use AFFF alcohol-resistant medium expansion foam. Move containers from fire area if you can do it without risk. Do not use straight streams. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Do not get water inside containers. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Stop leak if you can do it without risk. A vapor suppressing foam may be used to reduce vapors. FOR CHLOROSILANES, use AFFF alcohol-resistant medium expansion foam to reduce vapors. DO NOT GET WATER on spilled substance or inside containers. Use water spray to reduce vapors or divert vapor cloud drift. Prevent entry into waterways, sewers, basements or confined areas. Small spills: Cover with DRY earth, DRY sand, or other non-combustible material followed with plastic sheet to minimize spreading or contact with rain. Use clean non-sparking tools to collect material and place it into loosely covered plastic containers for later disposal.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Carefully fitted masks or respirators may be necessary when working with particulates or gases, & disposable plastic aprons might provide addnl protection. If gowns are of distinctive color, this is a reminder that they should not be worn outside of lab. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 8]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": ... Operations connected with synth & purification ... should be carried out under well-ventilated hood. Analytical procedures ... should be carried out with care & vapors evolved during ... procedures should be removed. ... Expert advice should be obtained before existing fume cupboards are used ... & when new fume cupboards are installed. It is desirable that there be means for decreasing the rate of air extraction, so that carcinogenic powders can be handled without ... powder being blown around the hood. Glove boxes should be kept under negative air pressure. Air changes should be adequate, so that concn of vapors of volatile carcinogens will not occur. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 8]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Vertical laminar-flow biological safety cabinets may be used for containment of in vitro procedures ... provided that the exhaust air flow is sufficient to provide an inward air flow at the face opening of the cabinet, & contaminated air plenums that are under positive pressure are leak-tight. Horizontal laminar-flow hoods or safety cabinets, where filtered air is blown across the working area towards the operator, should never be used ... Each cabinet or fume cupboard to be used ... should be tested before work is begun (eg, with fume bomb) & label fixed to it, giving date of test & avg air-flow measured. This test should be repeated periodically & after any structural changes. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 9]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Principles that apply to chem or biochem lab also apply to microbiological & cell-culture labs ... Special consideration should be given to route of admin. ... Safest method of administering volatile carcinogen is by injection of a soln. Admin by topical application, gavage, or intratracheal instillation should be performed under hood. If chem will be exhaled, animals should be kept under hood during this period. Inhalation exposure requires special equipment. ... unless specifically required, routes of admin other than in the diet should be used. Mixing of carcinogen in diet should be carried out in sealed mixers under fume hood, from which the exhaust is fitted with an efficient particulate filter. Techniques for cleaning mixer & hood should be devised before expt begun. When mixing diets, special protective clothing &, possibly, respirators may be required. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 9]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": When ... admin in diet or applied to skin, animals should be kept in cages with solid bottoms & sides & fitted with a filter top. When volatile carcinogens are given, filter tops should not be used. Cages which have been used to house animals that received carcinogens should be decontaminated. Cage-cleaning facilities should be installed in area in which carcinogens are being used, to avoid moving of ... contaminated /cages/. It is difficult to ensure that cages are decontaminated, & monitoring methods are necessary. Situations may exist in which the use of disposable cages should be recommended, depending on type & amt of carcinogen & efficiency with which it can be removed. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 10]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": To eliminate risk that ... contamination in lab could build up during conduct of expt, periodic checks should be carried out on lab atmospheres, surfaces, such as walls, floors & benches, & ... interior of fume hoods & airducts. As well as regular monitoring, check must be

carried out after cleaning-up of spillage. Sensitive methods are required when testing lab atmospheres. ... Methods ... should ... where possible, be simple & sensitive. ... /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 10]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Rooms in which obvious contamination has occurred, such as spillage, should be decontaminated by lab personnel engaged in expt. Design of expt should ... avoid contamination of permanent equipment. ... Procedures should ensure that maintenance workers are not exposed to carcinogens. ... Particular care should be taken to avoid contamination of drains or ventilation ducts. In cleaning labs, procedures should be used which do not produce aerosols or dispersal of dust, ie, wet mop or vacuum cleaner equipped with high-efficiency particulate filter on exhaust, which are avail commercially, should be used. Sweeping, brushing & use of dry dusters or mops should be prohibited. Grossly contaminated cleaning materials should not be re-used ... If gowns or towels are contaminated, they should not be sent to laundry, but ... decontaminated or burnt, to avoid any hazard to laundry personnel. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.

A passive monitor for **toluene** diisocyanate which utilizes microporous Teflon diffusion membranes and a 0.5% sulfuric acid absorbing medium was evaluated. The collection rate of **toluene** diisocyanate is proportional to exposure dose from 10 to at least 300 ppb.hr, and response is equivalent for 2,4- and 2,6-**toluene** diisocyanate. Collection rate is independent of humidity and normal atmospheric pressure variations, while temperature causes a decrease of 1.0% per deg C. Negative interference caused by ambient nitrogen dioxide is eliminated by addition of sulfamic acid to the collecting medium. N-Ethylmorpholine is a positive interferent. Field testing of the sampler against a reference impinger technique indicated a positive bias when **toluene** diisocyanate is aerosolized.
[Rando RJ et al; Am Ind Hyg Assoc J 50 (1): 8-14 (1989)]**PEER REVIEWED**

A solvent free sampling method for airborne **toluene** diisocyanate was described. Air samples were collected on quartz fiber filters impregnated with 1-(2-methoxyphenyl)piperazine. **Toluene** diisocyanate in the samples reacted with 1-(2-methoxyphenyl)piperazine to form urea derivatives which after dissolution in methanol were analyzed by reversed or normal phase HPLC. When reversed phase HPLC was used, a C18 bonded phase column was utilized. A cyano amino bonded phase column was used with normal phase HPLC. An ultraviolet detector set at a wavelength 250 nanometers was also used. Detection limits for a 15 liter air sample based on a 5 mm peak height were 0.02 to 0.04 mg/cu m, corresponding to 0.5 to 1 nanograms of **toluene** diisocyanate injected. The method was used to sample laboratory generated **toluene** diisocyanate containing atmospheres over the relative humidity range 11 to 75% and temperature range 20 to 50 deg C. In the study of the effects of humidity, samples were also

collected with gas bubblers and silica gel tubes for comparison purposes. **toluene** diisocyanate concn in the collected samples increased linearly with incr temperature. When the samples were collected on the 1-(2-methoxyphenyl)piperazine coated fibers the collected **toluene** diisocyanate concn were not affected by changes in relative humidity. Collection efficiency of the bubblers and silica gel tubes decr for humidities in excess of 45%. It was concluded that the 1-(2-methoxyphenyl)piperazine impregnated quartz fiber filter method for **toluene** diisocyanate sampling is convenient and efficient, and that collection efficiency does not appear to be affected by humidity.

A series of workers with exposure to and respiratory symptoms from **toluene** diisocyanate was compared with a group of exposed, asymptomatic workers and with normal controls using immunologic and clinical evaluations. Improved understanding of **toluene** diisocyanate-induced respiratory disease may best be achieved by categorizing the symptomatic workers into at least 3 and possibly 4 groups: immunologic asthma; pre-existing chronic respiratory disease exacerbated or unaffected by **toluene** diisocyanate; asthma coincidental with exposure, and possibly respiratory disease secondary to toxic or inflammatory mechanisms.
[Patterson R et al; Int Arch Allergy Appl Immunol 84 (1): 93-100 (1987)]**PEER REVIEWED**

Subjects exposed to 0.0010 to 0.0015 ppm of **toluene** diisocyanate demonstrated a normal age and smoking-related rate of decline in forced expiratory volume in 1 second and no evidence that it was related to isocyanate exposures.
[Musk AW et al; J Occup Med 27 (12): 917-20 (1985)]**PEER REVIEWED**

Twelve subjects were studied with inhalation challenge testing to **toluene** diisocyanate because of suspected asthma based on a consistent clinical and occupational history. In seven cases, asthma was documented by a positive inhalation challenge to low levels of **toluene** diisocyanate. Six of the seven reactors had persistent respiratory symptoms and required daily treatment even though they had been removed from isocyanate exposure for intervals as long as 12 years (mean 4.5 years). These six reactors had either dual (four cases) or late bronchospasm (two cases) to less than 20 ppb and all had a positive methacholine or cold air challenge prior to study. The one reactor with a negative methacholine challenge had a positive (immediate) bronchospastic response to a challenge performed one week after removal from isocyanate exposure. Five workers had a negative challenge, two of whom had persistent respiratory symptoms and positive methacholine challenges at the time of inhalation testing. ... Respiratory symptoms may persist following long-term removal from occupational exposure to and are associated with nonspecific bronchial hyperreactivity. The sensitivity may also persist for a long time even in the absence of any additional occupational exposure. Long-term prospective studies of symptomatic isocyanate workers are needed to fully define the extent of this problem.

[Moller DR et al; Chest 90 (4): 499 (1986)]**PEER REVIEWED**

Two workers who developed asthmatic symptoms were studied with inhalation provocation tests using ... **toluene** diisocyanate. Subjects did not show asthmatic reations to TDI challenge.
[Mapp CE et al; Ann Allergy 54 (5): 424-9 (1985)]**PEER REVIEWED**

Amine induced asthma was studied in polyurethane foam workers. A total of 12 subjects, occupationally exposed to polyurethane foams, who complained of wheezing and breathlessness at work were tested. Subjects were given 20 to 2000 ug methacholine. Forced expiratory volume in 1 sec was measured. Subjects were challenged with 0.01 ppm **toluene** diisocyanate for 15 min in an atmosphere chamber. Forced expiratory volume in 1 sec was measured. Positive tests were considered as a 15% fall in forced expiratory volume in 1 sec. High sensitivity to methacholine was seen in ten subjects with a 15% fall in forced expiratory volume in 1 sec at <1000 ug; normal subjects responded at 2000 ug. All subjects reacted to **toluene** diisocyanate.
[Cardura F, Moscata G; Brit J Indus Med 41: 552-3 (1984)]**PEER REVIEWED**

... The toxicity of inhaled vapors of diisocyanates is summarized. Humans are exposed to high concentrations of diisocyanates in polyurethane industries. Toxic symptoms are acute inflammation with lachrymation, rhinitis, soreness and burning in the throat and upper part of the chest, and coughing. Fire fighters are particularly prone to these clinical symptoms. The toxic limit value for **toluene** diisocyanate is 0.005 ppm. Exposure to diisocyanates can cause asthma.
[Davies RJ; Clinics in Immunology and Allergy 4 (1): 103-23 (1984)]**PEER REVIEWED**

The respiratory status of factory workers exposed continously to isocyanates over 10 years was studied. A total of 80 workers in two facilities that manufactured fixtures used in the interiors of cars were examined and underwent spirometry before and after work. Of these, 12 were comparisons not exposed to **toluene** diisocyanate. Subjects included those previously examined in 1971. Ventilatory capacity tests were performed inlcuding forced expiratory volume in 1 sec and forced vital capacity testing. Annual decrements were calculated. The mean average concentration of **toluene** diisocyanate was not more than 0.0033 ppm respectively. Subjects who had been studied previously had a mean forced vital capacity of 104.6% and a mean forced expiratory volume in 1 sec of 107% of predicted values. Three subjects with significant obstruction in the lung function tests were smokers. The comparisons in facility 1 had a significantly lower percentage of the predicted forced fital capacity and forced expiratory volume than the exposed population. Most of the data from 1971 for annual decrement calculations were not reliable. A 10% decrement in forced vital capacity and forced expiratory volume in 1 second was indicative of significant postshift decline and would indicate the presence of isocyanate asthma or hypersensitivity; no subject at either facility met the criteria.
[Gee JB; Morgan WKC; J Occup Med 27 (1): 15-8 (1985)]**PEER REVIEWED**

The mechanism by which late asthmatic reactions are induced by **toluene** diisocyanate, a low molecular weight chemical that causes occupational asthma in exposed subjects, is unknown. An investigation was conducted to determine whether early and late asthmatic reactions induced by **toluene** diisocyanate are associated with changes in airway responsiveness to methacholine and airway inflammation as determined by bronchoalveolar lavage. Forced expiratory volume in 1 second was measured before and at regular intervals after exposure to **toluene** diisocyanate and dose-response curves to methacholine and

bronchoalveolar lavage at 8 hr after **toluene** diisocyanate /were performed/ in a group of 6 subjects with late asthmatic reactions and in 6 subjects with only early asthmatic reactions. The same procedure was followed 2 hr after **toluene** diisocyanate in a group of 6 subjects with previously documented late asthmatic reactions and in a group of 6 subjects without any previously documented asthmatic reaction after **toluene** diisocyanate. In subjects with late asthmatic reactions, neutrophils were increased at both 2 hr and 8 hr and eosinophils and airway responsiveness were increased only at 8 hr. By contrast, neutrophils, eosinophils and airway responsiveness were not increased at 8 hr after **toluene** diisocyanate in subjectswith an early asthmatic reaction or at 2 hr after **toluene** diisocyanate in normal control subjects. These results suggest that late asthmatic reactions to **toluene** diisocyanate, and the associated increase in airway responsiveness may be caused by airway inflammation.
[Fabbri LM et al; Am Rev Respir Dis 136 (1): 36-42 (1987)]**PEER REVIEWED**

Technical grade **toluene** diisocyanate induced chromosome aberrations after a 24 hr treatment in the absence of metabolic activation in human whole blood lymphocyte cultures.
[Maki-Paakkanen J, Norppa H; Toxicol Lett 36 (1): 37-43 (1987)]**PEER REVIEWED**

To determine whether late asthmatic reactions and the associated increase in airway induced by **toluene** diisocyanate are linked to airway inflammation, inhibition by prednisone was investigated. Ten "sensitized" subjects were studied in 2 sets of experiments. In the first set, each subject was given no treatment and was studied before and for 8 hr after exposure to **toluene** diisocyanate. In the second set, 2 to 4 wk later, each subject was studied before treatment and then during treatment with prednisone (50 mg once a day for 3 days, orally), both before and after exposure to **toluene** diisocyanate. To assess late asthmatic reactions to **toluene** diisocyanate FEV1 /was measured/ immediately before and after exposure, then hourly for 8 hr. To assess changes in airway responsiveness, a /measurement was made of/ the provocation dose (mg) of methacholine causing a 20% decrease in FEV1 (PD20FEV1) before and 8 hr after exposure to **toluene** diisocyanate. When the subjects received no prednisione treatment, **toluene** diisocyanate caused late asthmatic reactions and increased airway responsiveness. By contrast, when the subjects received prednisone, **toluene** diisocyanate caused no late asthmatic reaction or increased airway responsiveness. Prednisone did not change baseline airway caliber or airway responsiveness. These results suggest that late asthmatic reactions and the associated increase in airway responsiveness induced by **toluene** diisocyanate in "sensitized" subjects may depend on the development of a steroid-responsive acute inflammatory reaction within the airways.
[Fabbri LM; Am Rev Respir Dis 132 (5): 1010-4 (1985)]**PEER REVIEWED**

Case reports of keratophathy in polyurethane production workers were examined. The experimental production of similar conditions was studied in cats and a monkey. A male polyurethane worker complained of blurred vision which improved over weekends away from work. The only significant finding on examination of the eyes was subepithelial corneal vesicles of 30 to 50 micrometers in diameter. A second patient, a female worker from the same facility, also complained of attacks of blurred vision. Slit lamp examination showed deep or subepithelial vacuolization only in the palpebral aperture. ... Corneas were normal between 3 day and 2 weeks. Exposure to **toluene** diisocyanate did not result in the clinical appearance of the eye resembling that of the workers.
[Potts AM et al; Am J Indust Med 9 (2): 203-13 (1986)]**PEER REVIEWED**

Symptoms and lung function of workers exposed to isocyanates in polyurethane foam factories were studied. A group of 67 workers was examined for **toluene**-diisocyanate ... exposure. Measurements were made by samples obtained from subject carried pumps. Interviews were also conducted for information of symptoms involving the nose, eyes, upper airways, and lung. Another group of 56 nonexposed workers was determined by spirometry and nitrogen wash out prior to the work shift. The exposed workers were examined again immediately after work. The variables studied were forced expired vital capacity and forced expired volume in 1 second. ... The highest exposure group was foaming machine workers, with a day mean exposure of 0.023 mg/cu m. Nonsmokers showed an increased frequency of symptoms involving the nose, throat, and dyspnea. Smokers had no significant increase. Smokers of the exposed group reported coughing. Only smokers reported symptoms classified as chronic bronchitis, with frequency independent of exposure. Decreased forced expired vital capacity and forced expired volume were observed in the exposed group. This group also showed increased expired vital capacity. Lung function impairment was restricted to smokers. Spirometric and nitrogen washout variables did not change significantly during the work shift. Decreasing spirometric values with increased exposure was seen in smokers. Conclusions indicate that mean exposure of 0.01 mg/cu m/day to isocyanates may give an increased frequency of symptoms in nonsmokers.

A survey of the incidence of occupational asthma in a steel coating factory was conducted. The survey was prompted by two male employees developing symptoms suggestive of occupational asthma. The cohort consisted of 221 males employed in the coating shop. A respiratory questionnaire was administered. Spirometric tests were conducted. Peak expiratory flow rate studies were performed on 50 subjects. Twenty one subjects reported symptoms of occupational asthma. Sixty three had other work related symptoms and 58 had respiratory symptoms unrelated to work. The mean length of employment of the subjects with asthmatic symptoms was 7.7 years. All symptomatic subjects had significantly reduced 1 second forced expiratory volumes, compared to asymptomatic workers. 21% of the peak expiratory flow rates were indicative of work related asthma. Two symptomatic subjects were administered inhalation challenge tests with **toluene** diisocyanate after it was discovered that one of the coatings that had been used for 8 years released **toluene** diisocyanate during the coating process. Both subjects showed decreases in forced expiratory volumes of at least 15% below the baseline values. Environmental sampling for **toluene** diisocyanate indicated concentrations ranging from below 0.001 to 0.026 ppm. The coating containing **toluene** diisocyanate was removed from the process. A follow-up survey conducted 1 year later showed that 17 of the symptomatic subjects had become asymptomatic or improved.
[Venables KM et al; Brit J Indus Med 42 (8): 517-24 (1985)]**PEER REVIEWED**

The presence of different thresholds on bronchial reactivity to **toluene** diisocyanate was tested in 20 spray painters employed in the furniture industry and affected by TDI induced asthma. Bronchial provocation tests failed to demonstrate nonspecific hyperreactivity to methacholine. Exposure of the workers to **toluene** diisocyanate in concentrations ranging from 0.02 to 0.25 ppm demonstrated the occurrence of low, moderate and high thresholds of airways response to **toluene** diisocyanate in nine, seven and four patients, respectively. There was no association between the **toluene** diisocyanate response threshold and the positive response pattern to the lower range of **toluene** diisocyanate levels, but six of the nine patients with low threshold of response to **toluene** diisocyanate and six of the 11

patients with moderate or high thresholds had nonspecific bronchial hyperreactivity. The response to **toluene** diisocyanate also was not associated with the duration of the asthmatic condition, smoking, cessation of work or nonspecific response to methacholine. The pattern of response was not dose dependent in ten of 13 patients who had two positive bronchial provocation tests with different levels of **toluene** diisocyanate, although dual responses were recorded in three patients who had late reactions at low concentrations of **toluene** diisocyanate. The value of forced expiratory volume in one second, recorded during immediate reactions, showed a dose response relationship, in that it declined by 28.4% at lower **toluene** diisocyanate levels as compared to 38.3% following inhalation of higher doses of the compound; no such association was established for the late reaction to **toluene** diisocyanate. The results conclude that patients who are sensitive to **toluene** diisocyanate may have different thresholds of response to the agent.
[Paggiaro PL et al; Respiration 50 (3): 167-73 (1986)]**PEER REVIEWED**

Respiratory variables were measured in workers exposed to **toluene** diisocyanate in Canada. Exposure and effect relationships were studied. Results from 95 isocyanate workers were compared with unexposed workers. Exposed workers were grouped according to production areas based on isocyanate concentrations measured. Individual monitors were worn to identify exposure for some workers. Symptoms and history of respiratory illness were compared through questionnaires. Pulmonary function tests included forced vital capacity, forced expiratory volume in 1 second, and forced expiratory flow at 50% and 75% of vital capacity. Pulmonary function was measured at the beginning and end of work shifts on Monday, Wednesday, and Friday of a work week. Regression analysis of exposure concentration and other variables was attempted. When comparisons were adjusted for smoking habits, exposed workers had a significantly lower family history of respiratory complaints. Isocyanate workers had slightly lower base line lung function than comparisons, but had significantly higher declines in pulmonary function over the work week. A 5% or greater decline over a day occurred in 44 percent of exposed but only 22% of comparison workers. Foam line and finishing area workers had greatest declines in forced vital capacity and forced expiratory volume in 1 second. It was concluded that although regression analysis does not show an exposure/effect relationship, an all or none effect may be operating with acute and chronic compartments. However, sample size may have been insufficient.

All workers develop eye, nose, and throat irritation at 0.5 ppm. Sensitized individuals may manifest symptoms at levels as low as 0.02 ppm.
[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 880]**PEER REVIEWED**

A worker developed **toluene** diisocyanate induced asthma in 1974. On reassessment, 11 yr after leaving the chemical plant where **toluene** diisocyanate was produced, he had no respiratory symptoms and normal bronchial reactivity in response to methacholine, and showed no reaction when challenged with a

subirritant concn of **toluene** diisocyanate. He developed asthma within five months of returning to the workplace. Repeat challenge testing showed bronchial hyperreactivity to methacholine and to the specific sensitising agent, **toluene** diisocyanate. This clinical pattern could be due to underlying **toluene** diisocyanate sensitivity with resolution and reappearance of hyperresponsiveness to methacholine and **toluene** diisocyanate reactivity associated with workplace **toluene** diisocyanate exposure. Alternatively, this worker may have developed sensitisation to **toluene** diisocyanate anew.
[Banks DE, Rando RJ; Thorax 43 (8): 1988 660-2]**PEER REVIEWED**

An investigation of the persistence of isocyanate induced asthma in workers with negligible occupational exposure was carried out. Six asthmatic workers, proven to be **toluene** diisocyanate sensitive by inhalation challenge testing in a longitudinal study of respiratory health risks associated with polyurethane foam production, were examined. The subjects were followed for 5 yr during which they completed a respiratory symptom questionnaire annually. Pulmonary function and responsiveness to methacholine challenge were measured annually. **toluene** diisocyanate concn in their breathing zones were measured. After the original survey the six subjects were transferred to areas thought to have negligible **toluene** diisocyanate exposures. None of the subjects had respiratory or asthmatic complaints before they started work in polyurethane production. The respiratory symptoms of the subjects did not improve during the followup period. All six had bronchial hyperresponsiveness to methacholine that did not resolve over time. Three subjects demonstrated deficits in 1 second forced expiratory volume of greater than 15% on one of the testing days during the followup period. The need for less or additional asthma therapy of the subjects could not be predicted. The mean time weighted average **toluene** diisocyanate exposure experienced by the subjects was 0.64 ppb; less than 5% of the OSHA standard of 20 ppb. It was concluded that although the outcome of isocyanate induced asthma cannot be predicted, the asthmatic symptoms of these workers have persisted despite the negligible **toluene** diisocyanate exposures.
[Banks DE et al; Chest 97 (1): 121-5 (1990)]**PEER REVIEWED**

The prevention of airway inflammation caused by **toluene** diisocyanate by prednisone was studied. Healthy **toluene** diisocyanate sensitive individuals were exposed to 0.018 ppm **toluene** diisocyanate in a test chamber. Bronchoalveolar lavage fluid was collected with a flexible fiberoptic bronchoscope. The lavage fluid was spun in a cytocentrifuge and stained with May/Grunwald/Giemsa for differential cell count. The total cell count was performed on resuspended cell pellets. A late asthmatic response was characterized by the occurrence of less than 20% of free expiratory volume in 1 second. The airway responsiveness was assessed by the reaction to methacholine. The cumulative dose of methacholine that produced a 20% decrease in forced expiratory volume in 1 second was used to measure airway responsiveness. Five subjects who received no prednisone treatment developed a late or dual asthmatic reaction. The albumin concn and total number of cells increased in subjects that were given no prednisone compared to controls. There was a significant increase in the number of neutrophils and a small increase in eosinophilia. There was no significant difference in the counts of other cell types. Results suggest that **toluene** diisocyanate induce late asthmatic reactions causing airway inflammation and that prednisone inhibits these reactions.
[Boschetto P et al; J Allergy Clin Immunol 80 (3):261-267 (1987)]**PEER REVIEWED**

Two men were exposed to **toluene** diisocyanate atmospheres at three different air concn (ca 25, 50 and 70 ug/cu m). The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8-cu m stainless-steel test chamber. The effective exposure

period was 4 hr. The isomeric composition of the air in the test chamber was 30% 2,4-**toluene** diisocyanate and 70% 2,6-**toluene** diisocyanate. The concn of **toluene** diisocyanate in air of the test chamber was determined by an HPLC method using the 9-(N-methyl-amino-methyl)-anthracene reagent and by a continuous-monitoring filter-tape instrument. Following the hydrolysis of plasma and urine, the related amines, 2,4-toluenediamine and 2,6-toluenediamine, were determined as pentafluoropropionic anhydride derivatives by capillary gas chromatography using selected ion monitoring in the electron impact mode. In plasma, 2,4- and 2,6-toluenediamine showed a rapid-phase elimination half-time of ca 2-5 hr, and that for the slow phase was greater than 6 days. A connection was observed between concn of 2,4- and 2,6-**toluene** diisocyanate in air and the levels of 2,4- and 2,6-toluenediamine in plasma. The cumulated amount of 2,4-toluenediamine excreted in the urine over 24 hr was ca 15%-19% of the estimated inhaled dose of 2,4-**toluene** diisocyanate, and that of 2,6-toluenediamine was ca 17%-23% of the inhaled dose of 2,6-**toluene** diisocyanate. A connection was found between the cumulated (24 hr) urinary excretion of 2,4- and 2,6-toluenediamine and the air concn of 2,4- and 2,6-**toluene** diisocyanate in the test chamber.
[Brorson T et al; Int Arch Occup Environ Health 63 (4): 253-9 (1991)]**PEER REVIEWED**

Thirty factory workers whose annual exposure to **toluene** diisocyanate amounted to 280 hr were examined. Seven of them had been removed from their jobs for presenting respiratory symptomatology and a further five were removed for presenting bronchial asthma. Their medical histories were consulted and further measures were taken such as a radiological thorax study, total immunoglobulin-E, **toluene** diisocyanate, diphenylmethane diisocyanate and hexamethylene diisocyanate RAST, a basal spirometric study and finally a provocation test. The Rast proved negative in every case. In the spirometric study carried out on the provocation test, four cases showed a significant decrease in the forced expiratory volume in 1 second over 20% and over 40% in the FMEF and PEFR. There was no connection between the four patients who presented an elevated total immunoglobulin-E and the four who presented a positive provocation test. The provocation test proved negative in five of the seven patients removed from their places of work. Two of the four workers who responded positively to the provocation test remained in their places of work during the **toluene** diisocyanate foam test without showing any symptoms. The patients who presented symptoms did not appear to present bronchial obstruction during the provocation test. Nonetheless, patients who seemingly had not shown any symptoms presented what appeared to be bronchial obstruction.

The nature of neurohumoral regulation was studied in 125 healthy workers, aged 20-40 yr, with different length of service and **toluene** diisocyanate exposure levels. Adrenal gland activity and some haematological parameters were determined. Neurohumoral regulation of adaptation processes in **toluene** diisocyanate exposed persons seemed to display some cyclicity, somehow related to the length of service. Two early regulatory phases (service up to 3 yr) had common features unrelated to the exposure levels, while after 3 yr of employment some dissimilarities evolved which did depend on the **toluene** diisocyanate exposure levels.
[Ermakova GA, Kryzanovskaja NA; Gigiena truda i Professional'nye Zabolevanija (7): 22-35 (1988)]**PEER REVIEWED**

Sensitized subjects may develop symptoms of asthma after exposure to isocyanates in their place of work. After challenge with isocyanates in the laboratory, sensitized subjects develop immediate, late and

dual asthmatic reactions. **Toluene** diisocyanate might cause late asthmatic reactions and increase bronchial responsiveness by causing an acute inflammatory reaction in the airways, and that airway inflammation may be responsible for persistence of occupational asthma induced by isocyanates. To test these hypotheses, sensitized subjects were examined during asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. It was observed that late and dual, but not early, asthmatic reactions are associated with a transient increase of bronchial responsiveness which is associated with an acute inflammatory reaction of the airways characterized by an increase of neutrophils followed by eosinophils, by an increase of leukotriene B4 and albumin in bronchoalveolar lavage fluid, and that all these effects are inhibited by steroids. Longitudinal studies suggest that the majority of subjects with occupational asthma continue to have persistent asthma months and yrs after the cessation of exposure, and the results of our studies combined with the results of studies performed by others suggest that the persistence of asthma may be related to the persistence of airway inflammation.
[Fabbri LM et al; Eur Respir J (Suppl 13): 136-38 (1991)]**PEER REVIEWED**

A shortened protocol was developed for the epidemiological measurement of bronchial responsiveness to methacholine without compromising sensitivity, power, precision or safety, and without distorting the numerical value of the PD20.FEV1 (the cumulative dose from a doubling incremental sequence which provokes a 20% decrement in forced expiratory volume in 1 second). It was used in a survey of 254 polyurethane workers (83% of the eligible workforce) exposed occupationally to **toluene** diisocyanate. The mean duration of each test proved to be 38 min, it was well tolerated and 64 workers (25%) proved to be reactors. PD20.FEV1 appeared to be distributed unimodally. It was significantly correlated with questionnaire records of shortness of breath, chest tightness, and wheeze; and with pre-shift forced expiratory volume in 1 second and FEF25-75. Even the reactors requiring the highest dose of 640 cumulative inhalation units (1 unit = one 8.9 ul inhalation of methacholine 1 mg/ml) to generate a PD20 measurement reported significantly more wheeze than the non-reactors. This indicates that the test had clinical meaning throughout its dose range of 0.3-640 units. No correlation was found between PD20 and individual changes in ventilatory function across the working shift, but mean shift changes were negligible and not statistically significant. PD20 was also found to be unrelated to age, sex, race, smoking, cough and atopy.
[Hendrick DJ; Bull Eur Physiopathol Respir 23 (6): 555-9 (1987)]**PEER REVIEWED**

Among the painters handling polyurethane varnish in two furniture manufacturing factories with high **toluene** diisocyanate exposure (0.79 mg/cu m and 0.31 mg/cu m), 26.3% and 15% subjects, respectively displayed asthmatic symptoms, lung function loss, and an increment in mast cell degranulation percentage specific to **toluene** diisocyanate. Some cases of **toluene** diisocyanate linked contact dermatitis were also found among them, being elucidated by positive patch testing to **toluene** diisocyanate. However, the previous abnormalities could not be verified among the painters from another factory with **toluene** diisocyanate concn below the TLV of it (0.11 mg/cu m). It was concluded that both pulmonary hypersensitivity and contact sensitization to **toluene** diisocyanate had occurred in some of the painters included in this study, and that the immunologic effects of **toluene** diisocyanate was concn dependent.
[Huang J et al; Arch Environ Contam Toxicol 21 (4): 607-11 (1991)]**PEER REVIEWED**

The importance of airways inflammation for the development of bronchial hyperresponsiveness and for

exacerbation of asthma was investigated in subjects with occupational asthma. Subjects sensitized to isocyanates, a small molecular weight compound that causes occupational asthma were examined. Studies in asthmatic subjects sensitized to **toluene** diisocyanate demonstrated that late, but not early, asthmatic reactions induced by **toluene** diisocyanate were associated with an acute increase in bronchial responsiveness, and with a marked infiltration of neutrophils and a slight infiltration of eosinophils into the airways, both prevented by steroids. As the late asthmatic reactions and the increase in responsiveness induced by **toluene** diisocyanate were prevented by steroids, but not by indomethacin, it was speculated that cell membrane phospholipid metabolites, which are inhibited by steroids but not by indomethacin, may be involved in **toluene** diisocyanate induced hyperresponsiveness. The results of these studies suggest that bronchial hyperresponsiveness and exacerbation of asthma may be related to inflammation of the airways and that cell membrane phospholipid metabolites may be involved.
[Mapp CE et al; Bull Eur Physiopathol Respir 23 (6): 583-6 (1987)]**PEER REVIEWED**

A study of individuals with occupational asthma induced by **toluene** diisocyanate was conducted. This was a followup of 35 patients, 25 males, with a history of isocyanate sensitization. They had 3 to 41 years' occupational exposure to isocyanate compounds. The subjects had been diagnosed with isocyanate asthma on the basis of their response to bronchial challenge with **toluene** diisocyanate. They were examined an average of 11 mo after diagnosis. They underwent bronchial challenge with **toluene** diisocyanate and methacholine. Forced expiratory volumes in 1 second were measured. Symptoms reported by the subjects were recorded. Twenty seven subjects were still asthmatic at followup as shown by a positive reaction to **toluene** diisocyanate challenge. They showed a deterioration in their forced expiratory volumes in 1 second and response to methacholine similar to that seen at diagnosis. Seventy seven percent of these subjects continued to have recurring attacks of dyspnea, wheezing, and cough which required medication. Twenty two of the asthma subjects had been removed from exposure. Subjects who recovered (did not react to **toluene** diisocyanate at the followup examination) showed an improvement in their forced expiratory volumes in 1 second and a reduced response to methacholine. At the time of diagnosis they tended to have an immediate or dual asthmatic reaction and were younger than the other subjects. The asthmatic subjects had dual or late reactions at diagnosis. It was concluded that respiratory symptoms, isocyanate sensitization, and airway hyperresponsiveness may persist for some time after exposure to **toluene** diisocyanate has ended.
[Mapp CE et al; Am Rev Respir Dis 137 (6): 1326-9 (1988)]**PEER REVIEWED**

Six workers with occupational asthma due to **toluene** diisocyanate were studied. For each worker a detailed clinical and occupational history was taken, and lung function measurement and skin intradermal tests for common allergens were carried out. Methacholine inhalation challenge was performed before **toluene** diisocyanate inhalation, and 8 hr after **toluene** diisocyanate inhalation. Methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, but went into the asthmatic range after **toluene** diisocyanate inhalation. These cases provid evidence that asthma can be induced by **toluene** diisocyanate in the absence of airway hyperresponsiveness. They further demonstrate that an isolated negative methacholine inhalation test cannot be used to exclude sensitization to **toluene** diisocyanate. Screening and follow-up studies on workers exposed on **toluene** diisocyanate require serial measurements of airway responsiveness and of variable air-flow obstruction.
[Mapp CE et al; Eur J Respir Dis 68 (2): 89-95 (1986)]**PEER REVIEWED**

The clinical findings and the results of inhalation challenge with **toluene** diisocyanate and methacholine in 113 subjects with a history of exposure to **toluene** diisocyanate and work-related respiratory symptoms are reported. Only some of the subjects (40.7%) had isocyanate asthma, diagnosed by a positive **toluene** diisocyanate inhalation challenge. Most reactors had a dual (30.4%) or a late (41.3%) response. The interval between the last occupational exposure and the specific challenge was significantly shorter in reactors, and among this group the number of immediate reactions to **toluene** diisocyanate decr progressively with an incr interval. The reactors had a significantly higher proportion of positive responses to methacholine and a significantly lower mean PD[1][5] FEV[1] (provocative dose of methacholine which provoked a 15% decrease in forced expiratory volume in 1 second): reactors 557:g, SEM 92.3; non-reactors 1346:g, SEM 128, P < .01. Methacholine challenge could not identify subjects with isocyanate asthma.
[Moscato G et al; J Occup Med 33 (6): 720-5 (1991)]**PEER REVIEWED**

Toluene diisocyanate is commonly used as the 2,4 and 2,6 isomers. NIOSH has estimated that 50,000 to 100,000 workers in the United States are regularly exposed to diisocyanates. As of 1977, 49,996 were estimated to be exposed to **toluene** diisocyanate alone. Methods for measuring diisocyanate exposures were considered. The current American Conference of Governmental Industrial Hygienists' recommended standard is 0.005 ppm time weighted average and 0.02 ppm peak for four 15 min periods a day. Results of exposure measurements taken in industry were summarized. Health effects of diisocyanates were discussed. In laboratory animals, **toluene** diisocyanate has caused inflammation and necrosis when applied directly to the skin, conjunctivitis when applied to the eyes, and rhinitis, laryngitis, tracheitis, bronchitis, and pneumonia when inhaled. Diisocyanates are potent pulmonary sensitizers capable of causing isocyanate asthma in humans. They can induce nonspecific airways disease and hypersensitivity pneumonitis after either acute or chronic exposure.
[Musk AW et al; Am J Ind Med 13 (3): 331-49 (1988)]**PEER REVIEWED**

A 46 yr old man who had worked in a paint processing plast for over 29 yr was admitted to our hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonitis due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against **toluene** diisocyanate-human serum albumin and diphenylmethane diisocyanate-human serum albumin, precipitating antibody against **toluene** diisocyanate-human serum albumin, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coombs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggests the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.
[Nozawa S et al; Nippon Kyobu Shikkan Gakkai Zasshi 27 (11): 1335-41 (1989)]**PEER REVIEWED**

Pulmonary function tests were done and compared to current and past potential exposure levels of **toluene** diisocyanate for 57 **toluene** diisocyanate manufacturing workers and 89 workers not exposed to **toluene** diisocyanate or other known respiratory hazards. The average **toluene** diisocyanate plant experience was 4.1 yr (standard deviation = 2.8). Routine industrial hygiene measurements have shown

toluene diisocyanate exposure below a time-weighted average of 0.005 ppm and a short-term exposure level of 0.02 ppm. A certified industrial hygienist ranked department and job classification by level of potential exposure to **toluene** diisocyanate (none, low, moderate, and high). A questionnaire was administered to determine the prevalence of respiratory symptoms and smoking habits. Using backward regression analysis, cumulative pack-years of cigarette smoking and prevalence of lower respiratory symptoms were statistically significant predictors of a standardized forced expiratory volume at 1 second; however, **toluene** diisocyanate exposure, whether classified as current, highest career level, cumulative, or cumulative highest-to-date, was not associated with a decline in forced expiratory volume.
[Olsen GW et al; J Occup Med 31 (8): 664-7 (1989)]**PEER REVIEWED**

Fifty seven polyurethane foam manufacturing workers and 24 reference workers were followed for 4 yr to clarify the effects on pulmonary function of working in polyurethane foam factories with exposure to **toluene** diisocyanate. No significant differences in the average annual losses of pulmonary function for 4 yr were observed among the 28 polyurethane foam workers whose **toluene** diisocyanate exposure levels were very low (mean = 0.1 ppb, group L), the remaining 29 polyurethane foam workers with mean **toluene** diisocyanate exposure of 5.7 ppb (group H), and the reference workers. However, 15 polyurethane foam workers in group H who had experienced peak exposure excursions to 30 ppb or above with a mean concn of 8.2 ppb showed significantly larger average annual losses in percentage maximal mid-expiratory flow, forced expiratory volume in 1 sec ratio to vital capacity, and forced expiratory flow at 25% of forced vital capacity than expected, and significantly larger average annual losses in some obstructive pulmonary function indices than those of the 14 remaining polyurethane foam workers in group H whose peak exposure excursion levels were 3-14 ppb with a mean time-weighted average of 1.7 ppb, group L, and the reference workers. These findings suggest that the peak exposure excursion level of **toluene** diisocyanate might be important in inducing obstructive pulmonary function changes in the polyurethane foam workers rather than the TWA exposure levels, though further comparative studies of the AAL in those who are exposed to different peak exposure excursion levels but the same mean exposure levels are necessary. From the standpoint of prevention, the proposition that peak exposure excursion levels exceeding 20 ppb should be avoided is reasonable.
[Omae K et al; Int Arch Occup Environ Health 63 (8): 565-9 (1992)]**PEER REVIEWED**

To evaluate the morphologic basis of the different outcomes of **toluene** diisocyanate asthma after quitting occupational exposure, ten patients with **toluene** diisocyanate asthma were examined who showed, at diagnosis, a positive **toluene** diisocyanate challenge test and nonspecific bronchial hyperresponsiveness to methacholine. After diagnosis, all patients ceased work and a 4 to 40 mo follow-up was obtained with three to eight determinations of the cumulative dose producing a 15% fall in forced expiratory volume in 1 second to methacholine in each patient. Bronchoalveolar lavage and biopsy of bronchial muscosa were performed 3 to 39 mo after cessation of work, in the absence of acute exacerbations of the disease. Total cell count in bronchoalveolar lavage fluid was moderately increased in four of ten patients, eosinophils were increased in five of ten patients, and neutrophils were increased in eight of ten patients. Mucosal biopsy specimens of main or lobar bronchi were available in eight of ten patients; epithelial damage and thickening of basement membrane was observed in almost all patients, as well as a mild to moderate inflammatory reaction in the submucosa, mainly represented by lymphocytes, eosinophils, and neutrophils. No relationship was observed between the cellularity of bronchoalveolar lavage and the degree of nonspecific bronchial hyperresponsiveness at the time of bronchoalveolar lavage; mean values of total cells and differential count were not different between patients with

presence or absence of the different histologic findings. Mucosal biopsy and bronchoalveolar lavage were performed also in four subjects exposed to dusts without respiratory symptoms or nonspecific bronchial hyperresponsiveness; similar findings were obtained except for the absence of eosinophils in bronchoalveolar lavage and a lesser degree of basement membrane thickening and inflammatory reaction in the submucosa. The study of the changes in nonspecific bronchial hyperresponsiveness after quitting exposure showed that five of ten patients had a significant improvement in nonspecific bronchial hyperresponsiveness to methacholine, as evaluated by a positive significant linear regression between months of work cessation and forced expiratory volume in 1 sec of methacholine; only one of these five patients had an increased number of eosinophils in bronchoalveolar lavage fluid. By contrast, four of the five patients with persistent nonspecific bronchial hyperresponsiveness after quitting exposure had an increased number of eosinophil in bronchoalveolar lavage. It is suggested that persistent nonspecific bronchial hyperresponsiveness in **toluene** diisocyanate asthma after cessation of work may be related to an inflammatory reaction in which eosinophil infiltration seems to be a major determinant.
[Paggiaro P et al; Chest 98 (3): 536-42 (1990)]**PEER REVIEWED**

The effect of cessation of exposure to **toluene** diisocyanate was studied in six patients with **toluene** diisocyanate induced asthma, proved by a positive inhalation challenge with **toluene** diisocyanate. Bronchial challenges with **toluene** diisocyanate and methacholine were performed, and lobar bronchial biopsies were taken at diagnosis and 6 mo later, after cessation of exposure. Biopsies from four nonasthmatic control subjects were also examined. At diagnosis, asthmatic subjects had thickened reticular basement membrane ($p < 0.05$) and increased numbers of mononuclear cells ($p < 0.05$) and eosinophils ($p < 0.05$) in the lamina propria when compared with control subjects. Electron microscopy showed degranulation of eosinophils and mast cells in asthmatics. Six months after cessation of exposure, the thickness of reticular basement membrane was significantly reduced compared with that at diagnosis ($p < 0.05$), and it decr to values similar to those of control biopsies. Inflammatory cell numbers in bronchial mucosa of asthmatic subjects did not change significantly 6 mo after removal from exposure, and degranulation of eosinophils and mast cells was still present. At the end of the study, airwa hyperresponsiveness to methacholine and/or sensitivity to **toluene** diisocyanate persisted in most of the asthmatic patients despite the cessation of exposure and the disappearance of asthmatic symptoms. In conclusion, in patients with occupational asthma induced by **toluene** diisocyanate, the avoidance of exposure to the sensitizing agent for 6 mo is able to reverse the reticular basement membrane thickening in the bronchial mucosa, but th inflammatory cell infiltrate, the specific sensitivity to **toluene** diisocyanate, and the nonspecific airway hyperreactivity may persist.
[Saetta M et al; Am Rev Respir Dis 145 (1): 169-74 (1992)]**PEER REVIEWED**

Forty-three workers exposed to low levels of **toluene** diisocyanate during the process of producing polyurethane forms were examined immunologically for immunoglobulin-G, A, M, and E and serum enzyme activities such as serum angiotensin converting enzyme, serum lysozyme and glycylproline dipeptidyl aminopeptidase. Air concn of **toluene** diisocyanate was annually measured in various places of work during the past five years from 1979 to 1983. The results obtained in the present study were as follows. The air concn of **toluene** diisocyanate at all places of work was below the permissible concn level of 0.02 ppm throughout the study period. Subjective symptoms and abnormal findings on chest X-ray considered directly related to **toluene** diisocyanate exposure were no observed. No remarkable abnormal findings in blood cell counts and in serum biochemical studies could be seen in any of the workers. The serum immunoglobulin-G levels in workers directly exposed to **toluene** diisocyanate were

significantly higher ($p < 0.05$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers. In the study of serum enzymatic activity, serum lysozyme activity in workers exposed directly to **toluene** diisocyanate was significantly higher ($p < 0.01$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers.
[Taniwaki H et al; Sangyo Igaku 29 (2): 130-5 (1987)]**PEER REVIEWED**

A case of building related health complaints was investigated with respect to the relationship among frequency of symptoms, antibodies to albumin conjugates of formaldehyde, **toluene** diisocyanate, and trimellitic anhydride, and volatile organic chemicals. The indoor air concn of volatile organic chemicals, formaldehyde, **toluene** diisocyanate and trimellitic anhydride did not exceed Fed-OSHA and ACGIH permissible standards. However, formaldehyde concn ranged between 0.05 and 0.08 ppm. The reported symptoms were multiple, involving the eyes, nose, sinuses, throat, lungs, skeletomuscular system and central nervous system. Anti-formaldehyde, **toluene** diisocyanate, and trimellitic anhydride isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. The data suggest that a synergistic immunological response to airborne chemicals may be occurring in these subjects. In conclusion, immunological monitoring of affected individuals where chemicals are suspected may prove to be useful in future investigations of building related illness.
[Thrasher JD et al; Am J Ind Med 15 (2): 187-95 (1989)]**PEER REVIEWED**

Diisocyanate inhalation tests (maximal concn, 20 ppb; exposure time, 1-2 hr) were performed using **toluene** diisocyanate (TDI, n = 15) and diphenylmethane diisocyanate (MDI, n = 7) as well as methacholine challenges in 19 workers who had a clinical history of **toluene** diisocyanate/diphenylmethane diisocyanate induced asthma. Additionally volunteers were tested who had n previous contact with diisocyanates: 10 healthy individuals with a negative methacholine test and 14 patients with asthma and a positive methacholine test were exposed to **toluene** diisocyanate. In all, 1 of the normal volunteers and 3 of the patients with asthma unrelated to diisocyanates showed a positive airway reaction to **toluene** diisocyanate, and 13 of the 19 diisocyanate workers displayed a positive result in the **toluene** diisocyanate/diphenylmethane diisocyanate inhalation test; however, only 6 of these 13 individuals reacted to methacholine. Furthermore, 3 of the 6 patients with a negative **toluene** diisocyanate/diphenylmethane diisocyanate challenge test demonstrated a significant response to methacholine. It was concluded that bronchial hyperreactivity as evaluated by the methacholine challenge test is not closely related to isocyanate induced bronchoconstriction and, therefore, the metacholine challenge is only of limited diagnostic value in patients with suspected isocyanate induced asthma.
[Vogelmeier C et al; Int Arch Occup Environ Health 63 (1): 9-13 (1991)]**PEER REVIEWED**

An outbreak of occupational asthma due to **toluene** diisocyanate among industrial workers was described. Four employees at a velcro/like tape manufacturing factory in Taipei, Taiwan were seen in an outpatient clinic complaining of cough, shortness of breath, and wheezing. The symptoms became worse at night and improved after long holidays. The patients' job involved applying an adhesive to the tape. Thirty eight of 45 employees were interviewed by questionnaire and given pulmonary function tests. The pulmonary function tests were given during a workday, after a 10 day holiday, and 5 mo after control measures such as process isolation, improved ventilation, and substitution for **toluene** diisocyanate were instituted. Industrial hygiene sampling for **toluene** diisocyanate was conducted. Fourteen workers had symptoms of asthma or asthmatic bronchitis. The highest attack rate occurred in workers employed in the

tape processing area where the adhesive was applied. Workers in the tape processing area also showed the greatest decr in 1 second forced expiratory volume and forced vital capacity over the workday. Mean **toluene** diisocyanate concn ranged from 0.012 to 0.047 ppm, the highest occurring in the tape processing area and the lowest in the weaving area. The prevalence of asthmatic symptoms was significantly correlated with **toluene** diisocyanate concn. The forced expiratory volume in 1 second and forced vital capacity values were significantly improved after the 10 day holiday and 5 mo after the control methods were instituted. No asthmatic symptoms were reported after 5 mo. It was concluded that **toluene** diisocyanate was responsible for the outbreak and improving the work environment was effective in reducing exposure to **toluene** diisocyanate.

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint materials containing **toluene** diisocyanate. His symptoms began 6 to 8 hr after exposure to the agent and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate-human serum albumin was present in bronchoalveolar lavage fluid and sera: IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate-human serum albumin. The histologic findings suggested hypersensitivity pneumonitis. The results of bronchoalveolar lavage, which was repeated on four separate occasions, showed lymphocytosis and a predominance of suppressor cytotoxic T cells. The findings from serial determinations of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to the agent.

A series of workers with exposure to and respiratory symptoms from **toluene** diisocyanate was compared with a group of exposed, asymptomatic workers and with normal controls using immunologic and clinical evaluations. Improved understanding of **toluene** diisocyanate-induced respiratory disease may best be achieved by categorizing the symptomatic workers into at least 3 and possibly 4 groups: immunologic asthma; pre-existing chronic respiratory disease exacerbated or unaffected by **toluene** diisocyanate; asthma coincidental with exposure, and possibly respiratory disease secondary to toxic or inflammatory mechanisms.
[Patterson R et al; Int Arch Allergy Appl Immunol 84 (1): 93-100 (1987)]**PEER REVIEWED**

Subjects exposed to 0.0010 to 0.0015 ppm of **toluene** diisocyanate demonstrated a normal age and smoking-related rate of decline in forced expiratory volume in 1 second and no evidence that it was related to isocyanate exposures.
[Musk AW et al; J Occup Med 27 (12): 917-20 (1985)]**PEER REVIEWED**

Twelve subjects were studied with inhalation challenge testing to **toluene** diisocyanate because of suspected asthma based on a consistent clinical and occupational history. In seven cases, asthma was documented by a positive inhalation challenge to low levels of **toluene** diisocyanate. Six of the seven reactors had persistent respiratory symptoms and required daily treatment even though they had been removed from isocyanate exposure for intervals as long as 12 years (mean 4.5 years). These six reactors had either dual (four cases) or late bronchospasm (two cases) to less than 20 ppb and all had a positive methacholine or cold air challenge prior to study. The one reactor with a negative methacholine challenge had a positive (immediate) bronchospastic response to a challenge performed one week after removal from isocyanate exposure. Five workers had a negative challenge, two of whom had persistent respiratory symptoms and positive methacholine challenges at the time of inhalation testing. ... Respiratory symptoms may persist following long-term removal from occupational exposure to and are associated with nonspecific bronchial hyperreactivity. The sensitivity may also persist for a long time even in the absence of any additional occupational exposure. Long-term prospective studies of symptomatic isocyanate workers are needed to fully define the extent of this problem.
[Moller DR et al; Chest 90 (4): 499 (1986)]**PEER REVIEWED**

Two workers who developed asthmatic symptoms were studied with inhalation provocation tests using ... **toluene** diisocyanate. Subjects did not show asthmatic reations to TDI challenge.

Amine induced asthma was studied in polyurethane foam workers. A total of 12 subjects, occupationally exposed to polyurethane foams, who complained of wheezing and breathlessness at work were tested. Subjects were given 20 to 2000 ug methacholine. Forced expiratory volume in 1 sec was measured. Subjects were challenged with 0.01 ppm **toluene** diisocyanate for 15 min in an atmosphere chamber. Forced expiratory volume in 1 sec was measured. Positive tests were considered as a 15% fall in forced

expiratory volume in 1 sec. High sensitivity to methacholine was seen in ten subjects with a 15% fall in forced expiratory volume in 1 sec at <1000 ug; normal subjects responded at 2000 ug. All subjects reacted to **toluene** diisocyanate.
[Cardura F, Moscata G; Brit J Indus Med 41: 552-3 (1984)]**PEER REVIEWED**

... The toxicity of inhaled vapors of diisocyanates is summarized. Humans are exposed to high concentrations of diisocyanates in polyurethane industries. Toxic symptoms are acute inflammation with lachrymation, rhinitis, soreness and burning in the throat and upper part of the chest, and coughing. Fire fighters are particularly prone to these clinical symptoms. The toxic limit value for **toluene** diisocyanate is 0.005 ppm. Exposure to diisocyanates can cause asthma.
[Davies RJ; Clinics in Immunology and Allergy 4 (1): 103-23 (1984)]**PEER REVIEWED**

The respiratory status of factory workers exposed continously to isocyanates over 10 years was studied. A total of 80 workers in two facilities that manufactured fixtures used in the interiors of cars were examined and underwent spirometry before and after work. Of these, 12 were comparisons not exposed to **toluene** diisocyanate. Subjects included those previously examined in 1971. Ventilatory capacity tests were performed inlcuding forced expiratory volume in 1 sec and forced vital capacity testing. Annual decrements were calculated. The mean average concentration of **toluene** diisocyanate was not more than 0.0033 ppm respectively. Subjects who had been studied previously had a mean forced vital capacity of 104.6% and a mean forced expiratory volume in 1 sec of 107% of predicted values. Three subjects with significant obstruction in the lung function tests were smokers. The comparisons in facility 1 had a significantly lower percentage of the predicted forced fital capacity and forced expiratory volume than the exposed population. Most of the data from 1971 for annual decrement calculations were not reliable. A 10% decrement in forced vital capacity and forced expiratory volume in 1 second was indicative of significant postshift decline and would indicate the presence of isocyanate asthma or hypersensitivity; no subject at either facility met the criteria.
[Gee JB; Morgan WKC; J Occup Med 27 (1): 15-8 (1985)]**PEER REVIEWED**

The mechanism by which late asthmatic reactions are induced by **toluene** diisocyanate, a low molecular weight chemical that causes occupational asthma in exposed subjects, is unknown. An investigation was conducted to determine whether early and late asthmatic reactions induced by **toluene** diisocyanate are associated with changes in airway responsiveness to methacholine and airway inflammation as determined by bronchoalveolar lavage. Forced expiratory volume in 1 second was measured before and at regular intervals after exposure to **toluene** diisocyanate and dose-response curves to methacholine and bronchoalveolar lavage at 8 hr after **toluene** diisocyanate /were performed/ in a group of 6 subjects with late asthmatic reactions and in 6 subjects with only early asthmatic reactions. The same procedure was followed 2 hr after **toluene** diisocyanate in a group of 6 subjects with previously documented late asthmatic reactions and in a group of 6 subjects without any previously documented asthmatic reaction after **toluene** diisocyanate. In subjects with late asthmatic reactions, neutrophils were increased at both 2 hr and 8 hr and eosinophils and airway responsiveness were increased only at 8 hr. By contrast, neutrophils, eosinophils and airway responsiveness were not increased at 8 hr after **toluene** diisocyanate in subjectswith an early asthmatic reaction or at 2 hr after **toluene** diisocyanate in normal control subjects. These results suggest that late asthmatic reactions to **toluene** diisocyanate, and the associated increase in airway responsiveness may be caused by airway inflammation.

To determine whether late asthmatic reactions and the associated increase in airway induced by **toluene** diisocyanate are linked to airway inflammation, inhibition by prednisone was investigated. Ten "sensitized" subjects were studied in 2 sets of experiments. In the first set, each subject was given no treatment and was studied before and for 8 hr after exposure to **toluene** diisocyanate. In the second set, 2 to 4 wk later, each subject was studied before treatment and then during treatment with prednisone (50 mg once a day for 3 days, orally), both before and after exposure to **toluene** diisocyanate. To assess late asthmatic reactions to **toluene** diisocyanate FEV1 /was measured/ immediately before and after exposure, then hourly for 8 hr. To assess changes in airway responsiveness, a /measurement was made of/ the provocation dose (mg) of methacholine causing a 20% decrease in FEV1 (PD20FEV1) before and 8 hr after exposure to **toluene** diisocyanate. When the subjects received no prednisione treatment, **toluene** diisocyanate caused late asthmatic reactions and increased airway responsiveness. By contrast, when the subjects received prednisone, **toluene** diisocyanate caused no late asthmatic reaction or increased airway responsiveness. Prednisone did not change baseline airway caliber or airway responsiveness. These results suggest that late asthmatic reactions and the associated increase in airway responsiveness induced by **toluene** diisocyanate in "sensitized" subjects may depend on the development of a steroid-responsive acute inflammatory reaction within the airways.
[Fabbri LM; Am Rev Respir Dis 132 (5): 1010-4 (1985)]**PEER REVIEWED**

Case reports of keratophathy in polyurethane production workers were examined. The experimental production of similar conditions was studied in cats and a monkey. A male polyurethane worker complained of blurred vision which improved over weekends away from work. The only significant finding on examination of the eyes was subepithelial corneal vesicles of 30 to 50 micrometers in diameter. A second patient, a female worker from the same facility, also complained of attacks of blurred vision. Slit lamp examination showed deep or subepithelial vacuolization only in the palpebral aperture. ... Corneas were normal between 3 day and 2 weeks. Exposure to **toluene** diisocyanate did not result in the clinical appearance of the eye resembling that of the workers.
[Potts AM et al; Am J Indust Med 9 (2): 203-13 (1986)]**PEER REVIEWED**

Symptoms and lung function of workers exposed to isocyanates in polyurethane foam factories were studied. A group of 67 workers was examined for **toluene**-diisocyanate ... exposure. Measurements were made by samples obtained from subject carried pumps. Interviews were also conducted for information of symptoms involving the nose, eyes, upper airways, and lung. Another group of 56 nonexposed workers was determined by spirometry and nitrogen wash out prior to the work shift. The exposed workers were examined again immediately after work. The variables studied were forced expired vital capacity and forced expired volume in 1 second. ... The highest exposure group was foaming machine workers, with a day mean exposure of 0.023 mg/cu m. Nonsmokers showed an increased frequency of symptoms involving the nose, throat, and dyspnea. Smokers had no significant increase. Smokers of the exposed group reported coughing. Only smokers reported symptoms classified as chronic bronchitis, with frequency independent of exposure. Decreased forced expired vital capacity and forced expired

volume were observed in the exposed group. This group also showed increased expired vital capacity. Lung function impairment was restricted to smokers. Spirometric and nitrogen washout variables did not change significantly during the work shift. Decreasing spirometric values with increased exposure was seen in smokers. Conclusions indicate that mean exposure of 0.01 mg/cu m/day to isocyanates may give an increased frequency of symptoms in nonsmokers.
[Alexanderson R et al; Internat Archives of Occup Environ Health 55 (2): 149-57 (1985)]**PEER REVIEWED**

A survey of the incidence of occupational asthma in a steel coating factory was conducted. The survey was prompted by two male employees developing symptoms suggestive of occupational asthma. The cohort consisted of 221 males employed in the coating shop. A respiratory questionnaire was administered. Spirometric tests were conducted. Peak expiratory flow rate studies were performed on 50 subjects. Twenty one subjects reported symptoms of occupational asthma. Sixty three had other work related symptoms and 58 had respiratory symptoms unrelated to work. The mean length of employment of the subjects with asthmatic symptoms was 7.7 years. All symptomatic subjects had significantly reduced 1 second forced expiratory volumes, compared to asymptomatic workers. 21% of the peak expiratory flow rates were indicative of work related asthma. Two symptomatic subjects were administered inhalation challenge tests with **toluene** diisocyanate after it was discovered that one of the coatings that had been used for 8 years released **toluene** diisocyanate during the coating process. Both subjects showed decreases in forced expiratory volumes of at least 15% below the baseline values. Environmental sampling for **toluene** diisocyanate indicated concentrations ranging from below 0.001 to 0.026 ppm. The coating containing **toluene** diisocyanate was removed from the process. A follow-up survey conducted 1 year later showed that 17 of the symptomatic subjects had become asymptomatic or improved.
[Venables KM et al; Brit J Indus Med 42 (8): 517-24 (1985)]**PEER REVIEWED**

The presence of different thresholds on bronchial reactivity to **toluene** diisocyanate was tested in 20 spray painters employed in the furniture industry and affected by TDI induced asthma. Bronchial provocation tests failed to demonstrate nonspecific hyperreactivity to methacholine. Exposure of the workers to **toluene** diisocyanate in concentrations ranging from 0.02 to 0.25 ppm demonstrated the occurrence of low, moderate and high thresholds of airways response to **toluene** diisocyanate in nine, seven and four patients, respectively. There was no association between the **toluene** diisocyanate response threshold and the positive response pattern to the lower range of **toluene** diisocyanate levels, but six of the nine patients with low threshold of response to **toluene** diisocyanate and six of the 11 patients with moderate or high thresholds had nonspecific bronchial hyperreactivity. The response to **toluene** diisocyanate also was not associated with the duration of the asthmatic condition, smoking, cessation of work or nonspecific response to methacholine. The pattern of response was not dose dependent in ten of 13 patients who had two positive bronchial provocation tests with different levels of **toluene** diisocyanate, although dual responses were recorded in three patients who had late reactions at low concentrations of **toluene** diisocyanate. The value of forced expiratory volume in one second, recorded during immediate reactions, showed a dose response relationship, in that it declined by 28.4% at lower **toluene** diisocyanate levels as compared to 38.3% following inhalation of higher doses of the compound; no such association was established for the late reaction to **toluene** diisocyanate. The results conclude that patients who are sensitive to **toluene** diisocyanate may have different thresholds of response to the agent.

[Paggiaro PL et al; Respiration 50 (3): 167-73 (1986)]**PEER REVIEWED**

Respiratory variables were measured in workers exposed to **toluene** diisocyanate in Canada. Exposure and effect relationships were studied. Results from 95 isocyanate workers were compared with unexposed workers. Exposed workers were grouped according to production areas based on isocyanate concentrations measured. Individual monitors were worn to identify exposure for some workers. Symptoms and history of respiratory illness were compared through questionnaires. Pulmonary function tests included forced vital capacity, forced expiratory volume in 1 second, and forced expiratory flow at 50% and 75% of vital capacity. Pulmonary function was measured at the beginning and end of work shifts on Monday, Wednesday, and Friday of a work week. Regression analysis of exposure concentration and other variables was attempted. When comparisons were adjusted for smoking habits, exposed workers had a significantly lower family history of respiratory complaints. Isocyanate workers had slightly lower base line lung function than comparisons, but had significantly higher declines in pulmonary function over the work week. A 5% or greater decline over a day occurred in 44 percent of exposed but only 22% of comparison workers. Foam line and finishing area workers had greatest declines in forced vital capacity and forced expiratory volume in 1 second. It was concluded that although regression analysis does not show an exposure/effect relationship, an all or none effect may be operating with acute and chronic compartments. However, sample size may have been insufficient.

All workers develop eye, nose, and throat irritation at 0.5 ppm. Sensitized individuals may manifest symptoms at levels as low as 0.02 ppm.
[Ellenhorn, M.J. and D.G. Barceloux. Medical Toxicology - Diagnosis and Treatment of Human Poisoning. New York, NY: Elsevier Science Publishing Co., Inc. 1988. 880]**PEER REVIEWED**

A worker developed **toluene** diisocyanate induced asthma in 1974. On reassessment, 11 yr after leaving the chemical plant where **toluene** diisocyanate was produced, he had no respiratory symptoms and normal bronchial reactivity in response to methacholine, and showed no reaction when challenged with a subirritant concn of **toluene** diisocyanate. He developed asthma within five months of returning to the workplace. Repeat challenge testing showed bronchial hyperreactivity to methacholine and to the specific sensitising agent, **toluene** diisocyanate. This clinical pattern could be due to underlying **toluene** diisocyanate sensitivity with resolution and reappearance of hyperresponsiveness to methacholine and **toluene** diisocyanate reactivity associated with workplace **toluene** diisocyanate exposure. Alternatively, this worker may have developed sensitisation to **toluene** diisocyanate anew.
[Banks DE, Rando RJ; Thorax 43 (8): 1988 660-2]**PEER REVIEWED**

An investigation of the persistence of isocyanate induced asthma in workers with negligible occupational exposure was carried out. Six asthmatic workers, proven to be **toluene** diisocyanate sensitive by inhalation challenge testing in a longitudinal study of respiratory health risks associated with

polyurethane foam production, were examined. The subjects were followed for 5 yr during which they completed a respiratory symptom questionnaire annually. Pulmonary function and responsiveness to methacholine challenge were measured annually. **toluene** diisocyanate concn in their breathing zones were measured. After the original survey the six subjects were transferred to areas thought to have negligible **toluene** diisocyanate exposures. None of the subjects had respiratory or asthmatic complaints before they started work in polyurethane production. The respiratory symptoms of the subjects did not improve during the followup period. All six had bronchial hyperresponsiveness to methacholine that did not resolve over time. Three subjects demonstrated deficits in 1 second forced expiratory volume of greater than 15% on one of the testing days during the followup period. The need for less or additional asthma therapy of the subjects could not be predicted. The mean time weighted average **toluene** diisocyanate exposure experienced by the subjects was 0.64 ppb; less than 5% of the OSHA standard of 20 ppb. It was concluded that although the outcome of isocyanate induced asthma cannot be predicted, the asthmatic symptoms of these workers have persisted despite the negligible **toluene** diisocyanate exposures.
[Banks DE et al; Chest 97 (1): 121-5 (1990)]**PEER REVIEWED**

The prevention of airway inflammation caused by **toluene** diisocyanate by prednisone was studied. Healthy **toluene** diisocyanate sensitive individuals were exposed to 0.018 ppm **toluene** diisocyanate in a test chamber. Bronchoalveolar lavage fluid was collected with a flexible fiberoptic bronchoscope. The lavage fluid was spun in a cytocentrifuge and stained with May/Grunwald/Giemsa for differential cell count. The total cell count was performed on resuspended cell pellets. A late asthmatic response was characterized by the occurrence of less than 20% of free expiratory volume in 1 second. The airway responsiveness was assessed by the reaction to methacholine. The cumulative dose of methacholine that produced a 20% decrease in forced expiratory volume in 1 second was used to measure airway responsiveness. Five subjects who received no prednisone treatment developed a late or dual asthmatic reaction. The albumin concn and total number of cells increased in subjects that were given no prednisone compared to controls. There was a significant increase in the number of neutrophils and a small increase in eosinophilia. There was no significant difference in the counts of other cell types. Results suggest that **toluene** diisocyanate induce late asthmatic reactions causing airway inflammation and that prednisone inhibits these reactions.
[Boschetto P et al; J Allergy Clin Immunol 80 (3):261-267 (1987)]**PEER REVIEWED**

Two men were exposed to **toluene** diisocyanate atmospheres at three different air concn (ca 25, 50 and 70 ug/cu m). The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8-cu m stainless-steel test chamber. The effective exposure period was 4 hr. The isomeric composition of the air in the test chamber was 30% 2,4-**toluene** diisocyanate and 70% 2,6-**toluene** diisocyanate. The concn of **toluene** diisocyanate in air of the test chamber was determined by an HPLC method using the 9-(N-methyl-amino-methyl)-anthracene reagent and by a continuous-monitoring filter-tape instrument. Following the hydrolysis of plasma and urine, the related amines, 2,4-toluenediamine and 2,6-toluenediamine, were determined as pentafluoropropionic anhydride derivatives by capillary gas chromatography using selected ion monitoring in the electron impact mode. In plasma, 2,4- and 2,6-toluenediamine showed a rapid-phase elimination half-time of ca 2-5 hr, and that for the slow phase was greater than 6 days. A connection was observed between concn of 2,4- and 2,6-**toluene** diisocyanate in air and the levels of 2,4- and 2,6-toluenediamine in plasma. The cumulated amount of 2,4-toluenediamine excreted in the urine over 24 hr was ca 15%-19% of the

estimated inhaled dose of 2,4-**toluene** diisocyanate, and that of 2,6-toluenediamine was ca 17%-23% of the inhaled dose of 2,6-**toluene** diisocyanate. A connection was found between the cumulated (24 hr) urinary excretion of 2,4- and 2,6-toluenediamine and the air concn of 2,4- and 2,6-**toluene** diisocyanate in the test chamber.
[Brorson T et al; Int Arch Occup Environ Health 63 (4): 253-9 (1991)]**PEER REVIEWED**

Thirty factory workers whose annual exposure to **toluene** diisocyanate amounted to 280 hr were examined. Seven of them had been removed from their jobs for presenting respiratory symptomatology and a further five were removed for presenting bronchial asthma. Their medical histories were consulted and further measures were taken such as a radiological thorax study, total immunoglobulin-E, **toluene** diisocyanate, diphenylmethane diisocyanate and hexamethylene diisocyanate RAST, a basal spirometric study and finally a provocation test. The Rast proved negative in every case. In the spirometric study carried out on the provocation test, four cases showed a significant decrease in the forced expiratory volume in 1 second over 20% and over 40% in the FMEF and PEFR. There was no connection between the four patients who presented an elevated total immunoglobulin-E and the four who presented a positive provocation test. The provocation test proved negative in five of the seven patients removed from their places of work. Two of the four workers who responded positively to the provocation test remained in their places of work during the **toluene** diisocyanate foam test without showing any symptoms. The patients who presented symptoms did not appear to present bronchial obstruction during the provocation test. Nonetheless, patients who seemingly had not shown any symptoms presented what appeared to be bronchial obstruction.
[Duce F et al; Allergol Immunopathol (Madr) 16 (3): 139-44 (1988)]**PEER REVIEWED**

The nature of neurohumoral regulation was studied in 125 healthy workers, aged 20-40 yr, with different length of service and **toluene** diisocyanate exposure levels. Adrenal gland activity and some haematological parameters were determined. Neurohumoral regulation of adaptation processes in **toluene** diisocyanate exposed persons seemed to display some cyclicity, somehow related to the length of service. Two early regulatory phases (service up to 3 yr) had common features unrelated to the exposure levels, while after 3 yr of employment some dissimilarities evolved which did depend on the **toluene** diisocyanate exposure levels.
[Ermakova GA, Kryzanovskaja NA; Gigiena truda i Professional'nye Zabolevanija (7): 22-35 (1988)]**PEER REVIEWED**

Sensitized subjects may develop symptoms of asthma after exposure to isocyanates in their place of work. After challenge with isocyanates in the laboratory, sensitized subjects develop immediate, late and dual asthmatic reactions. **Toluene** diisocyanate might cause late asthmatic reactions and increase bronchial responsiveness by causing an acute inflammatory reaction in the airways, and that airway inflammation may be responsible for persistence of occupational asthma induced by isocyanates. To test these hypotheses, sensitized subjects were examined during asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. It was observed that late and dual, but not early, asthmatic reactions are associated with a transient increase of bronchial responsiveness which is associated with an acute inflammatory reaction of the airways characterized by an increase of neutrophils followed by eosinophils, by an increase of leukotriene B4 and albumin in bronchoalveolar lavage fluid, and that all these effects are inhibited by steroids. Longitudinal studies suggest that the majority of subjects with occupational asthma continue to have persistent asthma months and yrs after the cessation of exposure,

and the results of our studies combined with the results of studies performed by others suggest that the persistence of asthma may be related to the persistence of airway inflammation.
[Fabbri LM et al; Eur Respir J (Suppl 13): 136-38 (1991)]**PEER REVIEWED**

A shortened protocol was developed for the epidemiological measurement of bronchial responsiveness to methacholine without compromising sensitivity, power, precision or safety, and without distorting the numerical value of the PD20.FEV1 (the cumulative dose from a doubling incremental sequence which provokes a 20% decrement in forced expiratory volume in 1 second). It was used in a survey of 254 polyurethane workers (83% of the eligible workforce) exposed occupationally to **toluene** diisocyanate. The mean duration of each test proved to be 38 min, it was well tolerated and 64 workers (25%) proved to be reactors. PD20.FEV1 appeared to be distributed unimodally. It was significantly correlated with questionnaire records of shortness of breath, chest tightness, and wheeze; and with pre-shift forced expiratory volume in 1 second and FEF25-75. Even the reactors requiring the highest dose of 640 cumulative inhalation units (1 unit = one 8.9 ul inhalation of methacholine 1 mg/ml) to generate a PD20 measurement reported significantly more wheeze than the non-reactors. This indicates that the test had clinical meaning throughout its dose range of 0.3-640 units. No correlation was found between PD20 and individual changes in ventilatory function across the working shift, but mean shift changes were negligible and not statistically significant. PD20 was also found to be unrelated to age, sex, race, smoking, cough and atopy.
[Hendrick DJ; Bull Eur Physiopathol Respir 23 (6): 555-9 (1987)]**PEER REVIEWED**

Among the painters handling polyurethane varnish in two furniture manufacturing factories with high **toluene** diisocyanate exposure (0.79 mg/cu m and 0.31 mg/cu m), 26.3% and 15% subjects, respectively displayed asthmatic symptoms, lung function loss, and an increment in mast cell degranulation percentage specific to **toluene** diisocyanate. Some cases of **toluene** diisocyanate linked contact dermatitis were also found among them, being elucidated by positive patch testing to **toluene** diisocyanate. However, the previous abnormalities could not be verified among the painters from another factory with **toluene** diisocyanate concn below the TLV of it (0.11 mg/cu m). It was concluded that both pulmonary hypersensitivity and contact sensitization to **toluene** diisocyanate had occurred in some of the painters included in this study, and that the immunologic effects of **toluene** diisocyanate was concn dependent.
[Huang J et al; Arch Environ Contam Toxicol 21 (4): 607-11 (1991)]**PEER REVIEWED**

The importance of airways inflammation for the development of bronchial hyperresponsiveness and for exacerbation of asthma was investigated in subjects with occupational asthma. Subjects sensitized to isocyanates, a small molecular weight compound that causes occupational asthma were examined. Studies in asthmatic subjects sensitized to **toluene** diisocyanate demonstrated that late, but not early, asthmatic reactions induced by **toluene** diisocyanate were associated with an acute increase in bronchial responsiveness, and with a marked infiltration of neutrophils and a slight infiltration of eosinophils into the airways, both prevented by steroids. As the late asthmatic reactions and the increase in responsiveness induced by **toluene** diisocyanate were prevented by steroids, but not by indomethacin, it was speculated that cell membrane phospholipid metabolites, which are inhibited by steroids but not by indomethacin, may be involved in **toluene** diisocyanate induced hyperresponsiveness. The results of these studies suggest that bronchial hyperresponsiveness and exacerbation of asthma may be related to

inflammation of the airways and that cell membrane phospholipid metabolites may be involved.
[Mapp CE et al; Bull Eur Physiopathol Respir 23 (6): 583-6 (1987)]**PEER REVIEWED**

A study of individuals with occupational asthma induced by **toluene** diisocyanate was conducted. This was a followup of 35 patients, 25 males, with a history of isocyanate sensitization. They had 3 to 41 years' occupational exposure to isocyanate compounds. The subjects had been diagnosed with isocyanate asthma on the basis of their response to bronchial challenge with **toluene** diisocyanate. They were examined an average of 11 mo after diagnosis. They underwent bronchial challenge with **toluene** diisocyanate and methacholine. Forced expiratory volumes in 1 second were measured. Symptoms reported by the subjects were recorded. Twenty seven subjects were still asthmatic at followup as shown by a positive reaction to **toluene** diisocyanate challenge. They showed a deterioration in their forced expiratory volumes in 1 second and response to methacholine similar to that seen at diagnosis. Seventy seven percent of these subjects continued to have recurring attacks of dyspnea, wheezing, and cough which required medication. Twenty two of the asthma subjects had been removed from exposure. Subjects who recovered (did not react to **toluene** diisocyanate at the followup examination) showed an improvement in their forced expiratory volumes in 1 second and a reduced response to methacholine. At the time of diagnosis they tended to have an immediate or dual asthmatic reaction and were younger than the other subjects. The asthmatic subjects had dual or late reactions at diagnosis. It was concluded that respiratory symptoms, isocyanate sensitization, and airway hyperresponsiveness may persist for some time after exposure to **toluene** diisocyanate has ended.
[Mapp CE et al; Am Rev Respir Dis 137 (6): 1326-9 (1988)]**PEER REVIEWED**

Six workers with occupational asthma due to **toluene** diisocyanate were studied. For each worker a detailed clinical and occupational history was taken, and lung function measurement and skin intradermal tests for common allergens were carried out. Methacholine inhalation challenge was performed before **toluene** diisocyanate inhalation, and 8 hr after **toluene** diisocyanate inhalation. Methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, but went into the asthmatic range after **toluene** diisocyanate inhalation. These cases provid evidence that asthma can be induced by **toluene** diisocyanate in the absence of airway hyperresponsiveness. They further demonstrate that an isolated negative methacholine inhalation test cannot be used to exclude sensitization to **toluene** diisocyanate. Screening and follow-up studies on workers exposed on **toluene** diisocyanate require serial measurements of airway responsiveness and of variable air-flow obstruction.
[Mapp CE et al; Eur J Respir Dis 68 (2): 89-95 (1986)]**PEER REVIEWED**

The clinical findings and the results of inhalation challenge with **toluene** diisocyanate and methacholine in 113 subjects with a history of exposure to **toluene** diisocyanate and work-related respiratory symptoms are reported. Only some of the subjects (40.7%) had isocyanate asthma, diagnosed by a positive **toluene** diisocyanate inhalation challenge. Most reactors had a dual (30.4%) or a late (41.3%) response. The interval between the last occupational exposure and the specific challenge was significantly shorter in reactors, and among this group the number of immediate reactions to **toluene** diisocyanate decr progressively with an incr interval. The reactors had a significantly higher proportion of positive responses to methacholine and a significantly lower mean PD[1][5] FEV[1] (provocative dose of methacholine which provoked a 15% decrease in forced expiratory volume in 1 second): reactors 557:g, SEM 92.3; non-reactors 1346:g, SEM 128, P < .01. Methacholine challenge could not identify

subjects with isocyanate asthma.
[Moscato G et al; J Occup Med 33 (6): 720-5 (1991)]**PEER REVIEWED**

Toluene diisocyanate is commonly used as the 2,4 and 2,6 isomers. NIOSH has estimated that 50,000 to 100,000 workers in the United States are regularly exposed to diisocyanates. As of 1977, 49,996 were estimated to be exposed to **toluene** diisocyanate alone. Methods for measuring diisocyanate exposures were considered. The current American Conference of Governmental Industrial Hygienists' recommended standard is 0.005 ppm time weighted average and 0.02 ppm peak for four 15 min periods a day. Results of exposure measurements taken in industry were summarized. Health effects of diisocyanates were discussed. In laboratory animals, **toluene** diisocyanate has caused inflammation and necrosis when applied directly to the skin, conjunctivitis when applied to the eyes, and rhinitis, laryngitis, tracheitis, bronchitis, and pneumonia when inhaled. Diisocyanates are potent pulmonary sensitizers capable of causing isocyanate asthma in humans. They can induce nonspecific airways disease and hypersensitivity pneumonitis after either acute or chronic exposure.
[Musk AW et al; Am J Ind Med 13 (3): 331-49 (1988)]**PEER REVIEWED**

A 46 yr old man who had worked in a paint processing plast for over 29 yr was admitted to our hospital with complaints of nocturnal dyspnea and dry cough. A chest X-ray film showed diffuse granular shadows in bilateral lungs. Pulmonary function tests revealed reduction of diffusing capacity and restrictive impairments. Hypersensitivity pneumonitis due to isocyanates was speculated from his occupational history and clinical course. Positive skin tests against **toluene** diisocyanate-human serum albumin and diphenylmethane diisocyanate-human serum albumin, precipitating antibody against **toluene** diisocyanate-human serum albumin, and negative lymphocyte stimulating tests of peripheral blood and bronchoalveolar lavage fluid were also noticed. Environmental provocation test was positive. Histological findings of transbronchial lung biopsy specimens showed diffuse alveolitis and Masson body, but no granulomas. According to these results, the patient was diagnosed as hypersensitivity pneumonitis due to **toluene** diisocyanate. Type III allergy of Gell-Coombs seems to participate in this case. The granulomatous lesion is seen less frequently in isocyanate related hypersensitivity pneumonitis than in hypersensitivity pneumonitis induced by organic dusts, which suggests the difference in immunological and histological reactions between both types of hypersensitivity pneumonitis.
[Nozawa S et al; Nippon Kyobu Shikkan Gakkai Zasshi 27 (11): 1335-41 (1989)]**PEER REVIEWED**

Pulmonary function tests were done and compared to current and past potential exposure levels of **toluene** diisocyanate for 57 **toluene** diisocyanate manufacturing workers and 89 workers not exposed to **toluene** diisocyanate or other known respiratory hazards. The average **toluene** diisocyanate plant experience was 4.1 yr (standard deviation = 2.8). Routine industrial hygiene measurements have shown **toluene** diisocyanate exposure below a time-weighted average of 0.005 ppm and a short-term exposure level of 0.02 ppm. A certified industrial hygienist ranked department and job classification by level of potential exposure to **toluene** diisocyanate (none, low, moderate, and high). A questionnaire was administered to determine the prevalence of respiratory symptoms and smoking habits. Using backward regression analysis, cumulative pack-years of cigarette smoking and prevalence of lower respiratory symptoms were statistically significant predictors of a standardized forced expiratory volume at 1 second; however, **toluene** diisocyanate exposure, whether classified as current, highest career level, cumulative, or cumulative highest-to-date, was not associated with a decline in forced expiratory volume.
[Olsen GW et al; J Occup Med 31 (8): 664-7 (1989)]**PEER REVIEWED**

Fifty seven polyurethane foam manufacturing workers and 24 reference workers were followed for 4 yr to clarify the effects on pulmonary function of working in polyurethane foam factories with exposure to **toluene** diisocyanate. No significant differences in the average annual losses of pulmonary function for 4 yr were observed among the 28 polyurethane foam workers whose **toluene** diisocyanate exposure levels were very low (mean = 0.1 ppb, group L), the remaining 29 polyurethane foam workers with mean **toluene** diisocyanate exposure of 5.7 ppb (group H), and the reference workers. However, 15 polyurethane foam workers in group H who had experienced peak exposure excursions to 30 ppb or above with a mean concn of 8.2 ppb showed significantly larger average annual losses in percentage maximal mid-expiratory flow, forced expiratory volume in 1 sec ratio to vital capacity, and forced expiratory flow at 25% of forced vital capacity than expected, and significantly larger average annual losses in some obstructive pulmonary function indices than those of the 14 remaining polyurethane foam workers in group H whose peak exposure excursion levels were 3-14 ppb with a mean time-weighted average of 1.7 ppb, group L, and the reference workers. These findings suggest that the peak exposure excursion level of **toluene** diisocyanate might be important in inducing obstructive pulmonary function changes in the polyurethane foam workers rather than the TWA exposure levels, though further comparative studies of the AAL in those who are exposed to different peak exposure excursion levels but the same mean exposure levels are necessary. From the standpoint of prevention, the proposition that peak exposure excursion levels exceeding 20 ppb should be avoided is reasonable.
[Omae K et al; Int Arch Occup Environ Health 63 (8): 565-9 (1992)]**PEER REVIEWED**

To evaluate the morphologic basis of the different outcomes of **toluene** diisocyanate asthma after quitting occupational exposure, ten patients with **toluene** diisocyanate asthma were examined who showed, at diagnosis, a positive **toluene** diisocyanate challenge test and nonspecific bronchial hyperresponsiveness to methacholine. After diagnosis, all patients ceased work and a 4 to 40 mo follow-up was obtained with three to eight determinations of the cumulative dose producing a 15% fall in forced expiratory volume in 1 second to methacholine in each patient. Bronchoalveolar lavage and biopsy of bronchial muscosa were performed 3 to 39 mo after cessation of work, in the absence of acute exacerbations of the disease. Total cell count in bronchoalveolar lavage fluid was moderately increased in four of ten patients, eosinophils were increased in five of ten patients, and neutrophils were increased in eight of ten patients. Mucosal biopsy specimens of main or lobar bronchi were available in eight of ten patients; epithelial damage and thickening of basement membrane was observed in almost all patients, as well as a mild to moderate inflammatory reaction in the submucosa, mainly represented by lymphocytes, eosinophils, and neutrophils. No relationship was observed between the cellularity of bronchoalveolar lavage and the degree of nonspecific bronchial hyperresponsiveness at the time of bronchoalveolar lavage; mean values of total cells and differential count were not different between patients with presence or absence of the different histologic findings. Mucosal biopsy and bronchoalveolar lavage were performed also in four subjects exposed to dusts without respiratory symptoms or nonspecific bronchial hyperresponsiveness; similar findings were obtained except for the absence of eosinophils in bronchoalveolar lavage and a lesser degree of basement membrane thickening and inflammatory reaction in the submucosa. The study of the changes in nonspecific bronchial hyperresponsiveness after quitting exposure showed that five of ten patients had a significant improvement in nonspecific bronchial hyperresponsiveness to methacholine, as evaluated by a positive significant linear regression between months of work cessation and forced expiratory volume in 1 sec of methacholine; only one of these five patients had an increased number of eosinophils in bronchoalveolar lavage fluid. By contrast, four of the five patients with persistent nonspecific bronchial hyperresponsiveness after quitting exposure had an

increased number of eosinophil in bronchoalveolar lavage. It is suggested that persistent nonspecific bronchial hyperresponsiveness in **toluene** diisocyanate asthma after cessation of work may be related to an inflammatory reaction in which eosinophil infiltration seems to be a major determinant.
[Paggiaro P et al; Chest 98 (3): 536-42 (1990)]**PEER REVIEWED**

The effect of cessation of exposure to **toluene** diisocyanate was studied in six patients with **toluene** diisocyanate induced asthma, proved by a positive inhalation challenge with **toluene** diisocyanate. Bronchial challenges with **toluene** diisocyanate and methacholine were performed, and lobar bronchial biopsies were taken at diagnosis and 6 mo later, after cessation of exposure. Biopsies from four nonasthmatic control subjects were also examined. At diagnosis, asthmatic subjects had thickened reticular basement membrane ($p < 0.05$) and increased numbers of mononuclear cells ($p < 0.05$) and eosinophils ($p < 0.05$) in the lamina propria when compared with control subjects. Electron microscopy showed degranulation of eosinophils and mast cells in asthmatics. Six months after cessation of exposure, the thickness of reticular basement membrane was significantly reduced compared with that at diagnosis ($p < 0.05$), and it decr to values similar to those of control biopsies. Inflammatory cell numbers in bronchial mucosa of asthmatic subjects did not change significantly 6 mo after removal from exposure, and degranulation of eosinophils and mast cells was still present. At the end of the study, airwa hyperresponsiveness to methacholine and/or sensitivity to **toluene** diisocyanate persisted in most of the asthmatic patients despite the cessation of exposure and the disappearance of asthmatic symptoms. In conclusion, in patients with occupational asthma induced by **toluene** diisocyanate, the avoidance of exposure to the sensitizing agent for 6 mo is able to reverse the reticular basement membrane thickening in the bronchial mucosa, but th inflammatory cell infiltrate, the specific sensitivity to **toluene** diisocyanate, and the nonspecific airway hyperreactivity may persist.
[Saetta M et al; Am Rev Respir Dis 145 (1): 169-74 (1992)]**PEER REVIEWED**

Forty-three workers exposed to low levels of **toluene** diisocyanate during the process of producing polyurethane forms were examined immunologically for immunoglobulin-G, A, M, and E and serum enzyme activities such as serum angiotensin converting enzyme, serum lysozyme and glycylproline dipeptidyl aminopeptidase. Air concn of **toluene** diisocyanate was annually measured in various places of work during the past five years from 1979 to 1983. The results obtained in the present study were as follows. The air concn of **toluene** diisocyanate at all places of work was below the permissible concn level of 0.02 ppm throughout the study period. Subjective symptoms and abnormal findings on chest X-ray considered directly related to **toluene** diisocyanate exposure were no observed. No remarkable abnormal findings in blood cell counts and in serum biochemical studies could be seen in any of the workers. The serum immunoglobulin-G levels in workers directly exposed to **toluene** diisocyanate were significantly higher ($p < 0.05$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers. In the study of serum enzymatic activity, serum lysozyme activity in workers exposed directly to **toluene** diisocyanate was significantly higher ($p < 0.01$) than those in workers indirectly exposed to **toluene** diisocyanate and in non-exposed workers.
[Taniwaki H et al; Sangyo Igaku 29 (2): 130-5 (1987)]**PEER REVIEWED**

A case of building related health complaints was investigated with respect to the relationship among frequency of symptoms, antibodies to albumin conjugates of formaldehyde, **toluene** diisocyanate, and trimellitic anhydride, and volatile organic chemicals. The indoor air concn of volatile organic chemicals, formaldehyde, **toluene** diisocyanate and trimellitic anhydride did not exceed Fed-OSHA and ACGIH permissible standards. However, formaldehyde concn ranged between 0.05 and 0.08 ppm. The reported

symptoms were multiple, involving the eyes, nose, sinuses, throat, lungs, skeletomuscular system and central nervous system. Anti-formaldehyde, **toluene** diisocyanate, and trimellitic anhydride isotypes were found in 12 of 14 full-time employees and were nondetectable in one part-time employee. The data suggest that a synergistic immunological response to airborne chemicals may be occurring in these subjects. In conclusion, immunological monitoring of affected individuals where chemicals are suspected may prove to be useful in future investigations of building related illness.
[Thrasher JD et al; Am J Ind Med 15 (2): 187-95 (1989)]**PEER REVIEWED**

Diisocyanate inhalation tests (maximal concn, 20 ppb; exposure time, 1-2 hr) were performed using **toluene** diisocyanate (TDI, n = 15) and diphenylmethane diisocyanate (MDI, n = 7) as well as methacholine challenges in 19 workers who had a clinical history of **toluene** diisocyanate/diphenylmethane diisocyanate induced asthma. Additionally volunteers were tested who had n previous contact with diisocyanates: 10 healthy individuals with a negative methacholine test and 14 patients with asthma and a positive methacholine test were exposed to **toluene** diisocyanate. In all, 1 of the normal volunteers and 3 of the patients with asthma unrelated to diisocyanates showed a positive airway reaction to **toluene** diisocyanate, and 13 of the 19 diisocyanate workers displayed a positive result in the **toluene** diisocyanate/diphenylmethane diisocyanate inhalation test; however, only 6 of these 13 individuals reacted to methacholine. Furthermore, 3 of the 6 patients with a negative **toluene** diisocyanate/diphenylmethane diisocyanate challenge test demonstrated a significant response to methacholine. It was concluded that bronchial hyperreactivity as evaluated by the methacholine challenge test is not closely related to isocyanate induced bronchoconstriction and, therefore, the metacholine challenge is only of limited diagnostic value in patients with suspected isocyanate induced asthma.
[Vogelmeier C et al; Int Arch Occup Environ Health 63 (1): 9-13 (1991)]**PEER REVIEWED**

An outbreak of occupational asthma due to **toluene** diisocyanate among industrial workers was described. Four employees at a velcro/like tape manufacturing factory in Taipei, Taiwan were seen in an outpatient clinic complaining of cough, shortness of breath, and wheezing. The symptoms became worse at night and improved after long holidays. The patients' job involved applying an adhesive to the tape. Thirty eight of 45 employees were interviewed by questionnaire and given pulmonary function tests. The pulmonary function tests were given during a workday, after a 10 day holiday, and 5 mo after control measures such as process isolation, improved ventilation, and substitution for **toluene** diisocyanate were instituted. Industrial hygiene sampling for **toluene** diisocyanate was conducted. Fourteen workers had symptoms of asthma or asthmatic bronchitis. The highest attack rate occurred in workers employed in the tape processing area where the adhesive was applied. Workers in the tape processing area also showed the greatest decr in 1 second forced expiratory volume and forced vital capacity over the workday. Mean **toluene** diisocyanate concn ranged from 0.012 to 0.047 ppm, the highest occurring in the tape processing area and the lowest in the weaving area. The prevalence of asthmatic symptoms was significantly correlated with **toluene** diisocyanate concn. The forced expiratory volume in 1 second and forced vital capacity values were significantly improved after the 10 day holiday and 5 mo after the control methods were instituted. No asthmatic symptoms were reported after 5 mo. It was concluded that **toluene** diisocyanate was responsible for the outbreak and improving the work environment was effective in reducing exposure to **toluene** diisocyanate.
[Wang JD et al; Am J Ind Med 14 (1): 73-8 (1988)]**PEER REVIEWED**

A 41 yr old automobile paint sprayer showed the clinical features of hypersensitivity pneumonitis 1 wk after he had begun to work with paint materials containing **toluene** diisocyanate. His symptoms began 6 to 8 hr after exposure to the agent and spontaneously disappeared by the next morning. He had diffuse, fine reticulonodular shadows on a chest roentgenogram and a restrictive impairment of pulmonary function. Immunoglobulin G antibody to **toluene** diisocyanate-human serum albumin was present in bronchoalveolar lavage fluid and sera: IgA antibody was present only in bronchoalveolar lavage fluid. Also, the patient had sensitized bronchoalveolar lymphocytes to **toluene** diisocyanate-human serum albumin. The histologic findings suggested hypersensitivity pneumonitis. The results of bronchoalveolar lavage, which was repeated on four separate occasions, showed lymphocytosis and a predominance of suppressor cytotoxic T cells. The findings from serial determinations of humoral antibodies showed no changes consistent with the results of clinical and laboratory studies. In contrast, blastogenic responses of bronchoalveolar lymphocytes to **toluene** diisocyanate markedly decr, and the patient showed clinical improvement despite continued exposure to the agent.

Medical Surveillance:

A SCREENING PROGRAM WAS UNDERTAKEN AT A RESEARCH & DEVELOPMENT FACILITY OF A LARGE **TOLUENE**-DIISOCYANATE (TDI) MANUFACTURING CORPORATION. THE PURPOSE WAS TO DETERMINE THE OCCURRENCE OF ANTIBODIES TO TDI IN SELECTED WORKER POPULATIONS. NO TOLYL-REACTIVE IMMUNOGLOBULIN-E ANTIBODIES WERE DETECTED IN SERA WHEN WORKERS WERE EXPOSED ONLY TO AMBIENT TDI CONCN. WORKERS HAD ACUTE EXPOSURES TO TDI AS A RESULT OF SPILLS OR SPLASHES. ANTIBODY RESPONSES DEVELOPED IN 3 OF 4 INDIVIDUALS WHOSE ACUTE EXPOSURES WERE ACCOMPANIED BY IMMEDIATE RESPIRATORY SYMPTOMATOLOGY & A DECREASED FORCED EXPIRATORY VOLUME. AN ANTIBODY RESPONSE DEVELOPED IN 1 OF 9 WORKERS & IMMEDIATE RESPIRATORY SYMPTOMS, BUT NO SPIROMETRIC CHANGES UPON ACUTE TDI EXPOSURE. ROUTINE SEROLOGIC SCREENING OF WORKERS FOR TOLYL-REACTIVE ANTIBODIES MAY BE OF VALUE IN CONFIRMING SUSPECTED ISOCYANATE EXPOSURE & IN PROVIDING AN EARLY WARNING OF DEVELOPING TDI HYPERSENSITIVITY.
[KAROL MH; J OCCUP MED 23 (11): 741 (1981)]**PEER REVIEWED**

MEDICAL EVALUATIONS OF 15 WORKERS WERE MADE TO DETERMINE THE HEALTH EFFECTS OF EXPOSURE TO TDI, PHOSGENE & TDA. THE FOLLOWING STEPS WERE RECOMMENDED: THE ENTIRE FACTORY POPULATION SHOULD BE SURVEYED PERIODICALLY FOR SYMPTOMS OF LOWER RESPIRATORY TRACT DISEASES & LUNG FUNCTION ABNORMALITIES THAT MAY BE CAUSED BY CHEMICAL EXPOSURE; TDI EXPOSURE SHOULD BE ENDED FOR SENSITIZED WORKERS OR FOR THOSE WITH EXCESSIVE DECLINE IN LUNG FUNCTION.
[COSTELLO RJ, PETERS JM; HEALTH HAZARD EVALUATION DETERMINATION REPORT NO HE-78-31-623, OLIN CORPORATION, ASHTABULA, OHIO 44004; REPORT NIOSH-HE-78-31-623, ORDER NO PB80-195274 (1979)]**PEER REVIEWED**

Comprehensive preplacement medical examinations should be given to each employee. The examination should include a pulmonary function test including FEV1, FVC, and FEV1/FVC, a history of diisocyanate exposure, smoking history, and history of respiratory conditions. The medical data obtained in the pre-placement examination can be used as a base line for periodic examination. Periodic examinations may be useful in detecting a reduction in lung function. Lung function tests, pulmonary history, and pulmonary physical exam should be repeated at least annually. All medical records, including pulmonary function and related medical tests, should be maintained for 30 years.

Probable Routes of Human Exposure:

Exposure to **toluene** diisocyanate is primarily occupational via inhalation or dermal contact with the aerosol or vapor. Workers may also be exposed through skin contact with freshly cured foam or as a result of spills or splashes. (SRC)
PEER REVIEWED

THE RESPIRATORY HEALTH OF 277 WORKERS IN A NEW **TOLUENE** DIISOCYANATE (TDI) MANUFACTURING PLANT WAS STUDIED PROSPECTIVELY DURING 5 YR OF EXPOSURE. PERSONAL TDI MONITORS WERE USED TO CONTINUOUSLY MEASURE PEAK & 8-HR TIME-WEIGHTED AVG (TWA) CONCN IN MORE THAN 2000 SAMPLES. REGRESSION OF ANNUAL CHANGE ON SMOKING (PACK-YEARS), ATOPIC STATUS & CUMULATIVE TDI EXPOSURE, DICHOTOMIZED AT 68.2 PPB MONTHS INTO LOW & HIGH EXPOSURE GROUPS, SHOWED SIGNIFICANT EFFECTS OF SMOKING ON SPIROMETRIC TESTS & LUNG VOLUMES. AFTER ADJUSTING FOR PACK-YEARS OF SMOKING, THE 74 MEN IN THE HIGH CUMULATIVE TDI EXPOSURE CATEGORY HAD SIGNIFICANTLY LARGER DECLINE IN FEV1 (1-S FORCED EXPIRATORY VOLUME), % FEV (% FORCED EXPIRATORY VOLUME) & FEF25-75% (FORCED EXPIRATORY FRACTION FROM 25 TO 75% VITAL CAPACITY) THAN DID THE 149 MEN IN THE LOW CATEGORY. ANNUAL CHANGE IN FEV1 WAS THEN EXAMINED IN 6 SMOKING-EXPOSURE CATEGORIES: IN NEVER-SMOKERS, AVG ANNUAL DECLINE WAS 38 ML/YR GREATER IN THOSE WITH HIGHER CUMULATIVE TDI EXPOSURE.

VAPORS OF THESE COMPD INVARIABLY BECOME AIRBORNE IN POLYMERIZATION REACTIONS, ESP SINCE HEAT & GAS ARE EVOLVED. /**TOLUENE** DIISOCYANATES/
[Hamilton, A., and H. L. Hardy. Industrial Toxicology. 3rd ed. Acton, Mass.: Publishing Sciences Group, Inc., 1974. 335]**PEER REVIEWED**

NIOSH (NOHS Survey 1972-1974) has statistically estimated that 29,284 workers are exposed to TDI in the USA(1). NIOSH (NOES Survey 1981-1983) has statistically estimated that 6,044 workers are exposed to TDI in the USA(2). Since the NOES survey excludes exposure to trade name chemicals which may contain the chemical, occupational exposure could be considerably higher(SRC).
[(1) NIOSH; National Occupational Health Survey (1974) (2) NIOSH; National Occupational Exposure Survey (1983)]**PEER REVIEWED**

Concentration medians for 2,4-**toluene** diisocyanate in 2 plants producing flexible polyurethane foam were 0.70 and 0.33 ppb for the mixing and finishing ends, respectively(1). The respective median values for 2,6-TDI were 0.91 and 1.1 ppb. Maximum concentrations of 2,6-TDI exceeded 64 ppb at the finishing end(1).
[(1) Rando RJ et al; Am Ind Hyg Assoc J 45: 199-203 (1984)]**PEER REVIEWED**

In a Finnish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(1). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(1). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4-isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(1). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(1). TDI levels of 1.3-2.8 ppb were detected in air inside a Swedish factory manufacturing polyurethanes(2).
[(1) Rosenberg C, Savolainen H; J Chromatography 367: 385-92 (1986) (2) Audunsson G et al; Intern J Environ Anal Chem 20: 85-100 (1985)]**PEER REVIEWED**

Mean concn ranges of TDI reported in ambient workplace air were 0.7-710 ug/cu m in TDI production, ND - 1490 ug/cu m during polyurethane foam production, 70-140 mg/cu m during elastomer production, 13 - 1050 ug/cu m during polyurethane foam use, 10-710 ug/cu m during polyurethane spray paint use, and <1-740 ug/cu m during the production of polyurethane-coated wire(1). Mean concn in personal samples ranged from ND-540 ug/cu m during polyurethane foam production and 2-1220 ug/cu m during polyurethane spray foam use(1). Additionally, mean concn of TDI released from insulation in a ship's hold was reported to be 120-150 ug/cu m and that released from coated fabric in a workplace 2-10 ug/cu m(1). During the outdoor application of TDI foam to a 40 ft diameter storage tanks, the mean atmospheric TDI concentration downwind from the spray gun was 0.3 ppm at 8 ft, 0.02 ppm at 40 ft, and 0.002 ppm at 150 ft(2). TDI was not detected more than 8 ft upwind of the spray gun(2). Air samples taken within two ft of the foam surface immediately after spraying had ceased was found to be 0.03 ppm(2). Mean TDI concentrations near the pumping equipment during material transfer was 0.02 ppm(2).

The following Overview, *** **TOLUENE** DIISOCYANATE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Toluene** diisocyanate is an irritant to skin, lungs, conjunctiva and gastrointestinal tract. Euphoria, ataxia, mental aberrations, sensitization (primarily respiratory), bronchitis, emphysema and cor pulmonale can occur.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Severe conjunctival irritation and lacrimation from liquid or high vapor concentrations is likely. Lower concentrations may produce a burning or prickling sensation.
- Glaucoma and iridocyclitis have been reported with a splash accident.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Burning or irritation of the nose and throat, cough, laryngitis, chest pain, and asthmatic syndrome (chemical bronchitis with severe bronchospasm), sensation of oppression or constriction of the chest, bronchitis, emphysema and cor pulmonale may occur.

- Respiratory symptoms may recur several years after discontinuation of exposure.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Acute exposures may produce headache, insomnia, euphoria, ataxia, anxiety neurosis with depression, or paranoid tendencies.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Inhalation of vapor or aerosol may produce vomiting and abdominal pain. Epigastric and substernal pain may be secondary to the paroxysmal or persistent cough associated with inhalation.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Irritation and inflammation are common. Dermal absorption is low.

IMMUNOLOGIC

0.2.19.1 ACUTE EXPOSURE

- Elevated specific IgE and IgG antibodies have been detected in sensitized and exposed workers. The presence of antibodies does is an indicator of exposure but not of sensitization.

CARCINOGENICITY

0.2.21.1 IARC CATEGORY

- **Toluene** diisocynate has been classified as a 2B agent: possibly carcinogenic to humans, based on sufficient evidence of carcinogenicity in experimental animals and no human data (IARC, 1987).

0.2.21.2 HUMAN OVERVIEW

- **Toluene** diisocyanate is considered a suspected or possible human carcinogen, based on sufficient evidence of carcinogenicity or tumors (spleen, subcutaneous, hepatic, ovarian, peritoneum, mammary gland tissues) in experimental animals (IARC, 1987; US DHHS, 1994; ACGIH, 1995).

Laboratory:

- Monitor respiratory function closely.

Treatment Overview:

ORAL EXPOSURE

- Due to the irritant nature of this substance, emesis is not advised.
- DILUTION: Immediately dilute with 4 to 8 ounces (120 to 240 mL) of milk or water (not to exceed 15 mL/kg in a child).
- ACTIVATED CHARCOAL: Administer charcoal as slurry (240 mL water/30 g charcoal). Usual dose: 25 to 100 g in adults/adolescents, 25 to 50 g in children (1 to 12 years), and 1 g/kg in infants less than 1 year old.
- Monitor patient for respiratory distress. If a cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis and pneumonia.
- Allergic reaction: Sensitized individuals should be cautioned to avoid further exposure as serious allergic reactions may result.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- Randomized, double-blind cross-over studies showed minimal efficacy of bronchodilators. This could be due to the absence of airway hyperresponsiveness in some TDI-induced asthma.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- Available dose-response information concerning humans pertains to inhalational exposure. Concentrations of 2.5 ppm are considered Immediately Dangerous to Life or Health. A fatality in an asthmatic who continued exposure to TDI has been reported.
- The recommended short term exposure limits for TDI in industry is 0.02 ppm. TDI does not have sufficient warning properties (e.g. odor or eye irritancy) at air concentrations below the recommended short term exposure limit.

Groups of 120 male and 120 female CD-1 mice, three to four weeks old, were exposed to 0, 0.05, or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production grade **toluene** diisocyanate (approx 80% 2,4 isomer & 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 104 wk. There was a significant reduction in body weight in the high-dose group /sex not stated/ and a significant increase in mortality in both high and low-dose females by the termination of the study. No such effect was seen in males. Neither the types of tumor observed nor their incidences were dose-related, and both corresponded to those seen in historical controls for this strain of mice. However, dose-related pathological changes were observed in the nasal cavity (chronic or necrotic rhinitis), together with changes in the lower respiratory tract (interstitial pneumonia, catarrhal bronchitis) in both groups.

The **toluene** diisocyanate induced delayed type hypersensitivity reaction in the ear of male mice was investigated and compared with the picryl chloride induced one. The results obtained were as follows: 1) When 1% **toluene** diisocyanate solution (20 ul/ear) as a challenging concentration was used for 7 week old ICR mice, distinct ear swelling was observed in every group sensitized with various concentrations (1-5%, 100 ul/animal) of **toluene** diisocyanate solution, and the swelling rate was the same or higher than that of picryl chloride induced delayed type hypersensitivity. 2) Five, 7 and 13 week old ICR mice showed a similar high response in TDI induced delayed type hypersensitivity, whereas the reactivity of 16 week old ICR mice was significantly lower than that of the above mentioned younger mice. 3) In both **toluene** diisocyanate and picryl chloride induced delayed type hypersensitivity reaction, ICR and BALB/c mice showed a similar high response, whereas the reactivity of ddY mice was significantly lower. The effects of dexamethasone and indomethacin were investigated with the **toluene** diisocyanate induced delayed type hypersensitivity model. The delayed type hypersensitivity reaction was suppressed significantly by both drugs, but the suppressive effects of dexamethasone were higher than that of indomethacin. All the above results indicate that the **toluene** diisocyanate induced delayed type hypersensitivity model in mice taking dye leakage as an index may be useful for evaluation of drugs for disorders derived from delayed type hypersensitivity reactions.
[Tominaga M et al; Jpn J Pharmacol 39 (2): 163-71 (1985)]**PEER REVIEWED**

Exposing guinea pigs to **toluene** diisocyanate causes an acute increase in airway responsiveness to inhaled acetylcholine. The mechanism of this increase in airway responsiveness is unknown. Capsaicin-sensitive afferent nerves and the tachykinins they release upon activation are important in controlling bronchomotor tone in guinea pigs. To determine whether tachykinins are important in **toluene** diisocyanate induced airway hyperresponsiveness, the effects of tachykinin depletion were studied using capsaicin, and competitive tachykinin antagonism, using (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P, on **toluene** diisocyanate induced airway hyperresponsiveness. In 9 of 9 untreated animals, **toluene** diisocyanate exposure caused a large and significant increase in airway responsiveness to acetylcholine. The mean concentration of acetylcholine required to decrease specific airway conductance by 50% below baseline (the PD50) was 1.51% before **toluene** diisocyanate exposure and 0.17% after **toluene** diisocyanate exposure ($p < 0.0005$). Capsaicin treatment had no effect on the PD50 but prevented the **toluene** diisocyanate induced increase in airway responsiveness in 10 of 12 animals. (The PD50 was 1.03% before **toluene** diisocyanate and 1.27% after **toluene** diisocyanate exposure.) Treatment with the tachykinin antagonist (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P also abolished the **toluene** diisocyanate induced increase in airway responsiveness in all 5 animals treated. Although **toluene** diisocyanate exposure also caused airway edema, the effect of capsaicin treatment on **toluene** diisocyanate induced hyperresponsiveness did not result from prevention of airway edema. **Toluene** diisocyanate exposure caused a marked increase in tracheal extravasation of intravenously administered Evans blue dye that was not prevented by capsaicin treatment.
[Thompson JE et al; Am Rev Respir Dis 136 (1): 43-9 (1987)]**PEER

REVIEWED**

The changes in airway responsiveness to increasing doses of an acetylcholine aerosol in anesthetized and ventilated guinea pigs 2, 6, or 24 hr after exposure to air or 1 ppm **toluene** diisocyanate were examined. Pulmonary resistance after the animals inhaled a buffered saline aerosol was used as baseline and was similar for air and groups. The concentration of acetylcholine calculated to cause a 200% increase in pulmonary resistance was significantly lower for animals studied at 2 hr (0.68%) or at 6 hr (0.77%), but not at 24 hr (2.39%), after than for air animals (3.07%). The increase in airway responsiveness in the exposed animals was associated with histologic changes in the trachea and intrapulmonary airways. Exposure to 2 ppm caused a patchy loss of cilia, shedding of epithelial cells into the airway lumen, and an influx of inflammatory cells into the trachea and other airways. In the lamina propria of the trachea, the concentration of extravascular polymorphonuclear leukocytes was 13 to 26-fold greater in animals studied 2 or 6 hr after exposure to 2 ppm **toluene** diisocyanate or at 2 hr after 1 ppm **toluene** diisocyanate than in animals exposed to air. The concentration of polymorphonuclear leukocytes in the epithelium was significantly increased only in animals examined 2 hr after 2 ppm **toluene** diisocyanate. Exposure to **toluene** diisocyanate also caused an influx of eosinophils into the tracheal mucosa. This influx occurred later and was more persistent than the influx of polymorphonuclear leukocytes. These results indicate that a single exposure to **toluene** diisocyanate can cause an increase in airway responsiveness that is associated with epithelial injury and acute airwayinflammation.
[Gordon T et al; Am Rev Respir Dis 132 (5): 1106-12 (1985)]**PEER REVIEWED**

The effect of exposure to **toluene** diisocyanate vapor on pulmonary performance was studied in guinea pigs. Female English smooth haired guinea pigs were exposed to 1.4 ppm **toluene** diisocyanate vapor or air for 3 hours per day for 4 days, or to 0.02 ppm **toluene** diisocyanate for 6 hours per day for 70 days. Pulmonary performance was evaluated by the ventilatory response of the animals to 10% carbon dioxide. Serum antibodies to **toluene** diisocyanate were measured on days 22 and 50 and **toluene** diisocyanate pulmonary hypersensitivity was measured on days 37 and 38. Lung tissue histopathology was evaluated in all animals on day 50 following **toluene** diisocyanate exposure. Pulmonary response to 10% carbon dioxide diminished by 30 to 50% following **toluene** diisocyanate exposures at 1.4 ppm up to day 14. The ventilatory response showed recovery during the next 5 weeks. In contrast, animals exposed to 0.02 ppm **toluene** diisocyanate daily for 70 days showed no change in ventilatory response, nor did control animals that were not exposed to **toluene** diisocyanate. Antibodies were detected on day 22 and pulmonary hyprsensitivity to **toluene** diisocyanate was found in all animals exposed to 1.4 ppm **toluene** diisocyanate. No antibodies to **toluene** diisocyanate nor pulmonary hypersensitivity were detected in animals exposed to 0.02 ppm **toluene** diisocyanate or in control animals. Lung tissue on day 50 in the 1.4 ppm **toluene** diisocyanate exposed animals showed multifocal subchronic interstitial inflammation, localized pleural thickening, and peripheral lymphoid hyperplasia. No apparent abnormalities were observed in lung tissue of the 0.02 ppm exposed group. Exposure to 1.4 or 0.02 ppm **toluene** diisocyanate resulted in measurable and no apparent pulmonary toxicity in guinea pigs, respectively. The 10 percent carbon dioxide challenge provide several advantages for measuring pulmonary function.
[Wang KL et al; J Toxicol Environ Health 15 (1): 137-48 (1985)]**PEER REVIEWED**

Groups of 50 F344/N rats of each sex and 50 B6C3F1 mice of each sex were gavaged with corn oil or a mixture of **toluene** diisocyanate in corn oil for 5 days per wk for 105 or 106 wk. Female rats and mice were given doses of 60 or 120 mg/kg body weight, while male rats received 30 or 60 mg/kg, and male

mice received 120 or 240 mg/kg. The **toluene** diisocyanate reacted with the moisture in the corn oil vehicle resulting in doses that were 10% to 23% below the target dose concn. The chemical product used was commercial grade **toluene** diisocyanate, which was an 80%-20% mixture of the 2,4- and 2,6-isomers. Chemical disposition and metabolism studies were conducted with each of the radiolabelled **toluene** diisocyanate isomers in male rats. Absorption of both of the **toluene** diisocyanate isomers occurred, with the highest concn found in the stomach, cecum, large intestine, and bladder. Excretion occurred via the feces and urine. The major metabolic products from the metabolism of 2,4-**toluene** diisocyanate were shown to be identical with those from the metabolism of the carcinogen, 2,4-diaminotoluene, whereas the metabolism of the 2,6-**toluene** diisocyanate isomer yielded one major product, identified as 2,6-bis(acetylamino)**toluene**. Greater than 10% depression in body weight gain occurred in all dosed groups of rats throughout most of the study. The major non-neoplastic lesions that were observed in both sexes of the **toluene** diisocyanate exposed rats were dose related incr in acute broncho-pneumonia, characterized as chemical pneumonitis, with incidences as high as 50%. In mice mean body weight gain was depressed in dosed male and in high dose females. The principle non-neoplastic lesion in mice that was attributed to chemical treatment was cytomegaly of the kidney tubular epithelium in males. Survival in all groups of dosed rats was significantly lower than in controls. A dose-dependent pattern of mortality did not commence until 70 wk of exposure, demonstrating that **toluene** diisocyanate elicited a cumulative toxic response. There was also significantly lower survival in high dose male, but not female mice, by comparison to controls. Despite the reduction of power and sensitivity in the rat studies caused by early mortality, statistically significant incr in tumor incidences were observed in many different target organs. **Toluene** diisocyanate was carcinogenic in F344/N rats, causing sc fibromas and fibrosarcomas in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland tumors in females.
[Dieter MP et al; Toxicol Ind Health 6 (6): 599-621 (1990)]**PEER REVIEWED**

Toluene diisocyanate is a causative agent in occupational asthma. Through an oral catheter **toluene** diisocyanate, 0.03 ul, dissolved in 0.02 ml olive oil, was superfused on the tracheobronchial mucosa of anaesthetized guinea pigs. **Toluene** diisocyanate induced plasma exudation into both airway tissue and lumen (peak effect: 5 hr; duration approximately 17 hr). Light microscopy examinations demonstrated that the epithelium was not disrupted by this process (and that microvessels are abundant just beneath the epithelium). At days 6 and 21 after exposure to **toluene** diisocyanate PAS-positive cells were increased, but no other histological alterations were found. Also, the occurrence of peptide containing nerve fibres was not altered by **toluene** diisocyanate. After **toluene** diisocyanate exposure the airway smooth muscle tone was elevated as examined in vitro at base-line and at conc response to carbachol. The largest incr in tone were recorded 21 days after exposure to **toluene** diisocyanate. The abnormally large tone was not associated with an increased thickness of the smooth muscle layer nor was it associated with reduced effects of either beta 2-agonist (terbutaline) or xanthine (theophylline) relaxants. It is concluded that **toluene** diisocyanate induced plasma exudation into guinea pig airways for 17 hr without disrupting the epithelial lining and without causing major changes in the airway peptidergic innervation. Both the airway tone, and the number of mucous cells, are increased for at least 3 wk after exposure to **toluene** diisocyanate.
[Persson CG et al; Clin Exp Allergy 21 (6): 715-24 (1991)]**PEER REVIEWED**

Toluene diisocyanate was mutagenic in Salmonella typhimurium strains TA98 and TA100 in the presence (but not the absence) of Aroclor 1254-induced male Sprague Dawley rat or male Syrian hamster liver S9; it was not mutagenic in strains TA 1535 or 1537.

National Toxicology Program Studies:

Groups of 50 female F344/N rats and 50 female B6C3F1 mice were administered commercial grade **toluene** diisocyanate (80% 2,4- and 20% 2,6-) in corn oil by gavage at doses of 60 or 120 mg/kg body weight, 5 days per week for 105 or 106 weeks. Groups of 50 male F344/N rats received 30 or 60 mg/kg and groups of 50 male B6C3F1 mice received 120 or 240 mg/kg on the same schedule. Dosage analyses of **toluene** diisocyanate indicated that the chemical had reacted in the corn oil vehicle, resulting in actual gavage concentrations 77% to 90% of theoretical values. Groups of 50 rats and 50 mice of each sex received corn oil only and served as vehicle controls. Survival in all groups of dosed rats in the 2-year studies was shorter (P less than or equal to 0.005) than that of the controls; depressions in mean body weight gain relative to controls were greater than 10% in all dosed rat groups throughout most of the study. A dose-dependent pattern of cumulative toxicity began at 70 weeks and culminated in excessive mortality, indicating the estimated maximum tolerated dose had been exceeded for rats. Acute bronchopneumonia occurred at increased incidences in groups of dosed male and female rats (males: control, 2/50; low dose, 6/50; high dose, 14/50; females: 1/50, 10/50, 25/49). /Results indicated that/ commercial grade **toluene** diisocyanate in corn oil was carcinogenic for F344/N rats, causing subcutaneous fibromas and fibrosarcomas (combined) in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland fibroadenomas in females. **Toluene** diisocyanate was not carcinogenic for male B6C3F1 mice. TDI was carcinogenic for female B6C3F1 mice, causing hemangiomas or hemangiosarcomas (combined), as well as hepatocellular adenomas.

Groups of 120 male and 120 female CD-1 mice, three to four weeks old, were exposed to 0, 0.05, or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production grade **toluene** diisocyanate (approx 80% 2,4 isomer & 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 104 wk. There was a significant reduction in body weight in the high-dose group /sex not stated/ and a significant increase in mortality in both high and low-dose females by the termination of the study. No such effect was seen in males. Neither the types of tumor observed nor their incidences were dose-related, and both corresponded to those seen in historical controls for this strain of mice. However, dose-related pathological changes were observed in the nasal cavity (chronic or necrotic rhinitis), together with changes in the lower respiratory tract (interstitial pneumonia, catarrhal bronchitis) in both groups.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 303 (1986)]**PEER REVIEWED**

Groups of 126 male and 126 female Sprague Dawley CD rats, six to nine weeks old, were exposed to 0, 0.05 or 0.15 ppm (0, 0.36 or 1.07 mg/cu m) production-grade **toluene** diisocyanate (approx 80% 2,4 isomer and 20% 2,6 isomer) in an inhalation chamber for 6 hr/day on 5 days/wk for 108 wk or 110 wk. A significant reduction in weight gain was observed during the first 12 wk of the study among the high-dose animals of each sex, but body wt gain was similar in all groups thereafter. No significant difference in mortality between treated and control groups of either sex was reported. Tumor incidences and types were reported to be similar in control and treated groups.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 304 (1986)]**PEER REVIEWED**

Rats receiving up to 240 mg/kg **toluene** diisocyanate by gavage daily on 5 days/wk for 13 wk were found to suffer from mild to moderate bronchopneumonia.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 306 (1986)]**PEER REVIEWED**

In dogs, a correlation has been made between immunological and respiratory responses to **toluene** diisocyanate. Dogs exposed once every second week for 41 wk to 1 mg/kg **toluene** diisocyanate delivered as an aerosol intratracheally developed a systemic immune response to **toluene** diisocyanate conjugated with dog serum albumin as well as immediate-type airway responses.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 307 (1986)]**PEER REVIEWED**

The **toluene** diisocyanate induced delayed type hypersensitivity reaction in the ear of male mice was investigated and compared with the picryl chloride induced one. The results obtained were as follows: 1) When 1% **toluene** diisocyanate solution (20 ul/ear) as a challenging concentration was used for 7 week old ICR mice, distinct ear swelling was observed in every group sensitized with various concentrations (1-5%, 100 ul/animal) of **toluene** diisocyanate solution, and the swelling rate was the same or higher than

that of picryl chloride induced delayed type hypersensitivity. 2) Five, 7 and 13 week old ICR mice showed a similar high response in TDI induced delayed type hypersensitivity, whereas the reactivity of 16 week old ICR mice was significantly lower than that of the above mentioned younger mice. 3) In both **toluene** diisocyanate and picryl chloride induced delayed type hypersensitivity reaction, ICR and BALB/c mice showed a similar high response, whereas the reactivity of ddY mice was significantly lower. The effects of dexamethasone and indomethacin were investigated with the **toluene** diisocyanate induced delayed type hypersensitivity model. The delayed type hypersensitivity reaction was suppressed significantly by both drugs, but the suppressive effects of dexamethasone were higher than that of indomethacin. All the above results indicate that the **toluene** diisocyanate induced delayed type hypersensitivity model in mice taking dye leakage as an index may be useful for evaluation of drugs for disorders derived from delayed type hypersensitivity reactions.
[Tominaga M et al; Jpn J Pharmacol 39 (2): 163-71 (1985)]**PEER REVIEWED**

Exposing guinea pigs to **toluene** diisocyanate causes an acute increase in airway responsiveness to inhaled acetylcholine. The mechanism of this increase in airway responsiveness is unknown. Capsaicin-sensitive afferent nerves and the tachykinins they release upon activation are important in controlling bronchomotor tone in guinea pigs. To determine whether tachykinins are important in **toluene** diisocyanate induced airway hyperresponsiveness, the effects of tachykinin depletion were studied using capsaicin, and competitive tachykinin antagonism, using (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P, on **toluene** diisocyanate induced airway hyperresponsiveness. In 9 of 9 untreated animals, **toluene** diisocyanate exposure caused a large and significant increase in airway responsiveness to acetylcholine. The mean concentration of acetylcholine required to decrease specific airway conductance by 50% below baseline (the PD50) was 1.51% before **toluene** diisocyanate exposure and 0.17% after **toluene** diisocyanate exposure ($p < 0.0005$). Capsaicin treatment had no effect on the PD50 but prevented the **toluene** diisocyanate induced increase in airway responsiveness in 10 of 12 animals. (The PD50 was 1.03% before **toluene** diisocyanate and 1.27% after **toluene** diisocyanate exposure.) Treatment with the tachykinin antagonist (D-Argl, D-Pro2, D-Trp7.9, Leull) substance P also abolished the **toluene** diisocyanate induced increase in airway responsiveness in all 5 animals treated. Although **toluene** diisocyanate exposure also caused airway edema, the effect of capsaicin treatment on **toluene** diisocyanate induced hyperresponsiveness did not result from prevention of airway edema. **Toluene** diisocyanate exposure caused a marked increase in tracheal extravasation of intravenously administered Evans blue dye that was not prevented by capsaicin treatment.
[Thompson JE et al; Am Rev Respir Dis 136 (1): 43-9 (1987)]**PEER REVIEWED**

The changes in airway responsiveness to increasing doses of an acetylcholine aerosol in anesthetized and ventilated guinea pigs 2, 6, or 24 hr after exposure to air or 1 ppm **toluene** diisocyanate were examined. Pulmonary resistance after the animals inhaled a buffered saline aerosol was used as baseline and was similar for air and groups. The concentration of acetylcholine calculated to cause a 200% increase in pulmonary resistance was significantly lower for animals studied at 2 hr (0.68%) or at 6 hr (0.77%), but not at 24 hr (2.39%), after than for air animals (3.07%). The increase in airway responsiveness in the exposed animals was associated with histologic changes in the trachea and intrapulmonary airways. Exposure to 2 ppm caused a patchy loss of cilia, shedding of epithelial cells into the airway lumen, and an influx of inflammatory cells into the trachea and other airways. In the lamina propria of the trachea, the concentration of extravascular polymorphonuclear leukocytes was 13 to 26-fold greater in animals

studied 2 or 6 hr after exposure to 2 ppm **toluene** diisocyanate or at 2 hr after 1 ppm **toluene** diisocyanate than in animals exposed to air. The concentration of polymorphonuclear leukocytes in the epithelium was significantly increased only in animals examined 2 hr after 2 ppm **toluene** diisocyanate. Exposure to **toluene** diisocyanate also caused an influx of eosinophils into the tracheal mucosa. This influx occurred later and was more persistent than the influx of polymorphonuclear leukocytes. These results indicate that a single exposure to **toluene** diisocyanate can cause an increase in airway responsiveness that is associated with epithelial injury and acute airwayinflammation.
[Gordon T et al; Am Rev Respir Dis 132 (5): 1106-12 (1985)]**PEER REVIEWED**

The effect of exposure to **toluene** diisocyanate vapor on pulmonary performance was studied in guinea pigs. Female English smooth haired guinea pigs were exposed to 1.4 ppm **toluene** diisocyanate vapor or air for 3 hours per day for 4 days, or to 0.02 ppm **toluene** diisocyanate for 6 hours per day for 70 days. Pulmonary performance was evaluated by the ventilatory response of the animals to 10% carbon dioxide. Serum antibodies to **toluene** diisocyanate were measured on days 22 and 50 and **toluene** diisocyanate pulmonary hypersensitivity was measured on days 37 and 38. Lung tissue histopathology was evaluated in all animals on day 50 following **toluene** diisocyanate exposure. Pulmonary response to 10% carbon dioxide diminished by 30 to 50% following **toluene** diisocyanate exposures at 1.4 ppm up to day 14. The ventilatory response showed recovery during the next 5 weeks. In contrast, animals exposed to 0.02 ppm **toluene** diisocyanate daily for 70 days showed no change in ventilatory response, nor did control animals that were not exposed to **toluene** diisocyanate. Antibodies were detected on day 22 and pulmonary hyprsensitivity to **toluene** diisocyanate was found in all animals exposed to 1.4 ppm **toluene** diisocyanate. No antibodies to **toluene** diisocyanate nor pulmonary hypersensitivity were detected in animals exposed to 0.02 ppm **toluene** diisocyanate or in control animals. Lung tissue on day 50 in the 1.4 ppm **toluene** diisocyanate exposed animals showed multifocal subchronic interstitial inflammation, localized pleural thickening, and peripheral lymphoid hyperplasia. No apparent abnormalities were observed in lung tissue of the 0.02 ppm exposed group. Exposure to 1.4 or 0.02 ppm **toluene** diisocyanate resulted in measurable and no apparent pulmonary toxicity in guinea pigs, respectively. The 10 percent carbon dioxide challenge provide several advantages for measuring pulmonary function.
[Wang KL et al; J Toxicol Environ Health 15 (1): 137-48 (1985)]**PEER REVIEWED**

Groups of 50 F344/N rats of each sex and 50 B6C3F1 mice of each sex were gavaged with corn oil or a mixture of **toluene** diisocyanate in corn oil for 5 days per wk for 105 or 106 wk. Female rats and mice were given doses of 60 or 120 mg/kg body weight, while male rats received 30 or 60 mg/kg, and male mice received 120 or 240 mg/kg. The **toluene** diisocyanate reacted with the moisture in the corn oil vehicle resulting in doses that were 10% to 23% below the target dose concn. The chemical product used was commercial grade **toluene** diisocyanate, which was an 80%-20% mixture of the 2,4- and 2,6-isomers. Chemical disposition and metabolism studies were conducted with each of the radiolabelled **toluene** diisocyanate isomers in male rats. Absorption of both of the **toluene** diisocyanate isomers occurred, with the highest concn found in the stomach, cecum, large intestine, and bladder. Excretion occurred via the feces and urine. The major metabolic products from the metabolism of 2,4-**toluene** diisocyanate were shown to be identical with those from the metabolism of the carcinogen, 2,4-diaminotoluene, whereas the metabolism of the 2,6-**toluene** diisocyanate isomer yielded one major product, identified as 2,6-bis(acetylamino)**toluene**. Greater than 10% depression in body weight gain occurred in all dosed groups of rats throughout most of the study. The major non-neoplastic lesions that

were observed in both sexes of the **toluene** diisocyanate exposed rats were dose related incr in acute broncho-pneumonia, characterized as chemical pneumonitis, with incidences as high as 50%. In mice mean body weight gain was depressed in dosed male and in high dose females. The principle non-neoplastic lesion in mice that was attributed to chemical treatment was cytomegaly of the kidney tubular epithelium in males. Survival in all groups of dosed rats was significantly lower than in controls. A dose-dependent pattern of mortality did not commence until 70 wk of exposure, demonstrating that **toluene** diisocyanate elicited a cumulative toxic response. There was also significantly lower survival in high dose male, but not female mice, by comparison to controls. Despite the reduction of power and sensitivity in the rat studies caused by early mortality, statistically significant incr in tumor incidences were observed in many different target organs. **Toluene** diisocyanate was carcinogenic in F344/N rats, causing sc fibromas and fibrosarcomas in males and females, pancreatic acinar cell adenomas in males, and pancreatic islet cell adenomas, neoplastic nodules of the liver, and mammary gland tumors in females.
[Dieter MP et al; Toxicol Ind Health 6 (6): 599-621 (1990)]**PEER REVIEWED**

Toluene diisocyanate is a causative agent in occupational asthma. Through an oral catheter **toluene** diisocyanate, 0.03 ul, dissolved in 0.02 ml olive oil, was superfused on the tracheobronchial mucosa of anaesthetized guinea pigs. **Toluene** diisocyanate induced plasma exudation into both airway tissue and lumen (peak effect: 5 hr; duration approximately 17 hr). Light microscopy examinations demonstrated that the epithelium was not disrupted by this process (and that microvessels are abundant just beneath the epithelium). At days 6 and 21 after exposure to **toluene** diisocyanate PAS-positive cells were increased, but no other histological alterations were found. Also, the occurrence of peptide containing nerve fibres was not altered by **toluene** diisocyanate. After **toluene** diisocyanate exposure the airway smooth muscle tone was elevated as examined in vitro at base-line and at conc response to carbachol. The largest incr in tone were recorded 21 days after exposure to **toluene** diisocyanate. The abnormally large tone was not associated with an increased thickness of the smooth muscle layer nor was it associated with reduced effects of either beta 2-agonist (terbutaline) or xanthine (theophylline) relaxants. It is concluded that **toluene** diisocyanate induced plasma exudation into guinea pig airways for 17 hr without disrupting the epithelial lining and without causing major changes in the airway peptidergic innervation. Both the airway tone, and the number of mucous cells, are increased for at least 3 wk after exposure to **toluene** diisocyanate.

Metabolism/Pharmacokinetics:

Metabolism/Metabolites:

A technique for detectingurinary amine metabolites in rats exposed to **toluene** diisocyanate was evaluated. Skin tissue of rats was exposed to 40% **toluene**-2,4-diisocyanate solution in di-n-butyl-ether liquid. Rats were exposed daily for 3 hr on 4 consecutive days. Urine was collected in metabolic cages for 18 hr after the last exposure. Chromatographic techniques were used for nitrogen selective detection of nonderivatized amines. An autolinear temperature programmer was employed to analyze derivatized amine. The identity of the amine was confirmed by gas chromatography/mass spectrometry. A linear correlation was found between **toluene**-2,4-diamine added to urine and peak height. Peak height and recovery from the non hydrolyzed and from the hydrolyzed urine was about 85 and 70%, respectively. No free **toluene**-2,4-diamine or free **toluene**-2,4-diisocyanate was detected in the urine of rats exposed to **toluene**-2,4-diamine in hydrolyzed urine was 1.5 micrograms per milliliter. Gas chromatography/mass spectrometry confirmed the identity of the amine. /This/ highly sensitive technique tested is easy to apply and is effective for trace assays of amines.
[Rosenberg C; J Chromatography 323 (2): 429-33 (1985)]**PEER REVIEWED**

Epithelial injury and inflammation are involved in airway hyperresponsiveness and asthma induced by **toluene** diisocyanate. In that isocyanates are insoluble and highly reactive compounds, bronchial epithelial cells may represent the most important target cells of their toxic effect. We hypothesized that damage to airway epithelium by **toluene** diisocyanate may result in the release of metabolites of arachidonic acid, which are known to promote inflammation and to alter epithelial cell function and airway smooth muscle responsiveness. To test this hypothesis we examined eicosanoid products in the culture media of bronchial epithelial cells exposed in vitro to 8 and 18 ppb **toluene** diisocyanate. Epithelial cells derived from human bronchi obtained at surgery were cultured to confluency on collagen-coated microporous membranes. Those cells, which expressed differentiated characteristics of epithelial cells (they showed keratin-containing filaments and had a cobblestone appearance), were alternatively exposed to **toluene** diisocyanate or air for 30 min in a specially designed in vitro chamber. The production of metabolites of arachidonic acid was assessed by measuring the release of immunoreactive products into the cell medium at the end of the exposure and during a 2 hr period after exposure. This method revealed a predominant isocyanate induced release of immunoreactive 15-hydroxyeicosatetraenoic acid. Release rate of this compound tended to be dose-related and was associated with cell damage as assessed by the release of lactate dehydrogenase in the medium.
[Mattoli S et al; J Cell Physiol 142 (2): 379-85 (1990)]**PEER REVIEWED**

It has been previously shown that tachykinin depletion or antagonism prevented the increase in airway responsiveness to inhaled acetylcholine caused by exposure to **toluene** diisocyanate in awake guinea pigs. To insure that the effects of tachykinins were not limited to the extrathoracic airways and were not dependent on effects of **toluene** diisocyanate on baseline airway caliber, airway responsiveness to acetylcholine inhaled through tracheostomy in anesthetized and ventilated guinea pigs that were exposed

to **toluene** diisocyanate or air after treatment with the tachykinin antagonist spantide, the tachykinin metabolism inhibitor phosphoramidon, or the vehicles for each drug were determined. When these drugs were administered before and during **toluene** diisocyanate exposure, spantide significantly inhibited the **toluene** diisocyanate induced increase in acetylcholine responsiveness and phosphoramidon significantly potentiated this effect, whereas neither drug altered acetylcholine responsiveness in air exposed animals. To determine whether tachykinins were exerting their effect primarily during **toluene** diisocyanate exposure or during the subsequent acetylcholine challenge, the effect of each drug on acetylcholine responsiveness was also examined when the drugs were given after **toluene** diisocyanate exposure. At that time, spantide did not inhibit **toluene** diisocyanate induced acetylcholine hyperresponsiveness and phosphoramidon did not potentiate it. Neither drug nor **toluene** diisocyanate increased pulmonary resistance measured through a tracheostomy in these anesthetized and ventilated animals. These results suggest that the **toluene** diisocyanate induced increase in acetylcholine responsiveness is mediated by release of tachykinins into the intrathoracic airways during exposure to **toluene** diisocyanate.
[Sheppard D, Scypinski L; Am Rev Respir Dis 138 (3): 547-51 (1988)]**PEER REVIEWED**

Five men were exposed to **toluene** diisocyanate atmospheres for 7.5 hr. The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8 cu m stainless steel test chamber. The mean air concn of **toluene** diisocyanate was ca 40 ug/cu m, which corresponds to the TLV of Sweden. The inhaled doses of 2,4- and 2,6-**toluene** diisocyanate were ca 120 ug. **Toluene** diisocyanate in the test chamber air was determined by an HPLC method using the 9-(N-methylaminomethyl)-anthracene reagent and by a continuous monitoring filter-tape instrument. After hydrolysis of plasma and urine, the related amines, 2,4- and 2,6-toluenediamine 2,4-, and 2,6-TDA), were determined as pentafluoropropionic anhydride derivatives by capillary gas-chromatography using selected ion monitoring in the electron-impact mode. The urinary elimination of the toluenediamines showed a possible biphasic pattern, with rapid first phases for 2,4-toluenediamine (mean half-life for the concn in urine, 1.9 hr) and for 2,6-toluenediamine (mean half-life for the concn in urine, 1.6 hr). The cumulative amount of 2,4-toluenediamine excreted in urine within 28 hr ranged from 8% to 14% of the estimated dose of 2,4-**toluene** diisocyanate, and the cumulative amount of 2,6-toluenediamine in urine ranged from 14% to 18% of the 2,6-**toluene** diisocyanate dose. The average urinary level of 2,4-toluenediamine was 5 ug/l in the 6 to 8 hr sample (range 2.8-9.6 ug/l), and the corresponding value fo 2,6-toluenediamine was 8.6 ug/l (range, 5.6-16.6 ug/l). Biological monitoring of exposure to 2,4- and 2,6-**toluene** diisocyanate by analysis of 2,4- and 2,6-toluenediamine in urine is feasible.
[Skarping G et al; Int Arch Occup Environ Health 63 (2): 83-8 (1991)]**PEER REVIEWED**

Mechanism of Action:

SERUM FROM 26 PERSONS SHOWN TO REACT TO PROVOCATIVE INHALATION CHALLENGE WITH LOW CONCN OF **TOLUENE** DIISOCYANATE WAS TESTED BY RADIOALLERGOSORBENT TEST (RAST) USING A P-TOLYL ISOCYANATE-HUMAN SERUM ALBUMIN (TMI-HSA) CONJUGATE. POSITIVE RESULTS WERE OBTAINED IN 15-19% OF **TOLUENE** DIISOCYANATE REACTORS, DEPENDING ON THE METHOD OF EVALUTION. **TOLUENE** DIISOCYANATE ASTHMA MAY BE A COMPLEX SYNDROME WITH SEVERAL TYPES OF REACTIONS POSSIBLE, INCLUDING AN IMMUNOGLOBULIN-E MECHANISM IN SOME INDIVIDUALS. THE THEORY THAT **TOLUENE** DIISOCYANATE ASTHMA IS BASED

SOLELY ON AN IMMUNE MECHANISM IS NOT SUPPORTED. THE FINDINGS DO NOT DISAGREE WITH THE HYPOTHESIS THAT **TOLUENE** DIISOCYANATE REACTIVITY MAY BE MEDIATED BY A PHARMACOLOGIC MECHANISM.
[BUTCHER BT ET AL; J ALLERGY CLIN IMMUNOL 66 (3): 213 (1980)]**PEER REVIEWED**

To investigate the role of pharmacological mechanisms in **toluene** diisocyanate induced occupational asthma, the effects of **toluene** diisocyanate on rat trachea ring and lung parenchymal strip were studied in vitro. The most prominent effect observed was a stimulation of metacholine induced contraction of the tracheal ring by 1M **toluene** diisocyanate (added in dimethyl sulfoxide). The results were less pronounced when **toluene** diisocyanate was added from a stock solution prepared in water, which is possibly due to copolymerisation. It is concluded that the pharmacological effect of **toluene** diisocyanate may result from an autonomic imbalance between cholinergic and B-adrenergic neural control.
[Borm PJA et al; Br J Ind Med 46 (1): 56-9 (1989)]**PEER REVIEWED**

A study of the occurrence of serum immunoglobulin-E and immunoglobulin-G antibodies in workers with isocyanate induced asthma was conducted. The study group consisted of 62 workers (58 males) being evaluated for occupational asthma. Thirty nine had been exposed to hexamethylene diisocyanate, 17 to diphenylmethane diisocyanate, and six to **toluene** diisocyanate. The subjects completed a respiratory and occupational questionnaire. Spirometric tests were administered. Skin prick tests were performed with 15 common inhalant allergens and **toluene** diisocyanate, hexamethylene diisocyanate, and diphenylmethane diisocyanate human serum albumin conjugates. Blood samples were collected and assayed for specific serum immunoglobulin-G and immunoglobulin-E antibodies to hexamethylene diisocyanate, diphenylmethan diisocyanate, and **toluene** diisocyanate. Specific inhalation challenges were conducted with hexamethylene diisocyanate, diphenylmethane diisocyanate, and **toluene** diisocyanate. Specific inhalation challenge with **toluene** diisocyanate, hexamethylene diisocyanate, or diphenylmethane diisocyanate induced significant bronchoconstriction in half of the subjects, late reactions being the most common. Twenty subjects had significantly elevated immunoglobulin-G concn and nine had significantly elevated immunoglobulin-G plus immunoglobulin-E concn. Six of 12 subjects with elevated immunoglobulin-E and immunoglobulin-G antibodies had positive skin prick tests for hexamethylene diisocyanate and one was sensitized to diphenylmethane diisocyanate. It was concluded that an association between isocyanate specific antibodies and the results of specific inhalation challenge tests has been established. This suggests that isocyanate induced asthma may involve an immunological mechanism.
[Cartier A et al; J Allergy Clin Immunol 84 (4 Part 1): 507-14 (1989)]**PEER REVIEWED**

The influence of cyclophosphamide induced granulocyte depletion on **toluene** diisocyanate related changes in airway reactivity and pathology was assessed in guinea pigs. Twelve cyclophosphamide-treated and 12 control animals comprising each group were studied physiologically before and 2 hr after a single 10 min exposure to 3 ppm of **toluene** diisocyanate. Reactivity was determined in intact unanesthetized animals by measuring specific airway conductance before and during intravenous acetylcholine infusion. After testing, tracheal tissue for light microscopic examination was obtained from three hyperreactive guinea pigs in each exposed group and compared with tissue from treated and control animals (n = 3 each) that had not been **toluene** diisocyanate exposed. Cyclophosphamide treatment caused substantial decr in both circulating and airway granulocyte counts. However, the incidence and degree of bronchial hyperreactivity that occurred 2 hr post-**toluene**

diisocyanate was similar in the untreated and treated groups. Results indicate that **toluene** diisocyanate induced bronchial hyperreactivity 1) occurs shortly after a brief high concn exposure and 2) appears independent of circulating or airway granulocyte counts.
[Cibulas W Jr et al; J Appl Physiol 64 (5): 1773-8 (1988)]**PEER REVIEWED**

To determine the importance of airway inflammation for the development of late asthmatic reactions, we examined sensitized subjects during late asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. Late asthmatic reactions are associated with a transient increase of bronchial responsiveness and, at the same time, with an increase of neutrophils followed by eosinophils, and of leukotriene B4 and albumin in bronchoalveolar lavage fluid. Late asthmatic reactions, increased bronchial responsiveness, and increase of neutrophils, eosinophils, leukotriene B4, and albumin concn in bronchoalveolar lavage induced by exposure to **toluene** diisocyanate are all prevented by pretreatment with prednisone but not with the nonsteroidal anti-inflammatory agent indomethacin. Aerosolized steroids (beclomethasone and dexamethasone isonicotinate) completely inhibit late asthmatic reactions induced by **toluene** diisocyanate, whereas theophylline has a partial, and verapamil, ketotifen, and cromolyn have no protective effect. These results suggest that late asthmatic reactions induced by **toluene** diisocyanate may be caused by airway inflammation, and that anti-inflammatory steroids should be recommended in the prophylaxis of **toluene** diisocyanate asthma.
[Fabbri LM et al; Am Rev Respir Dis 143 (3 Pt 2): 537-8 (1991)]**PEER REVIEWED**

The effects of **toluene** diisocyanate on T-cell subpopulations and circulating lymphocytes in ten persons (five males)): 19 to 50 yr old, with **toluene** diisocyanate induced occupational asthma were examined. Five subjects revealed early and late asthmatic reactions to **toluene** diisocyanate (dual responders) and five revealed late asthmatic reactions (late responders). Subjects underwent inhalation challenge with 0.005 to 0.015 ppm **toluene** diisocyanate or filtered air for 10 to 30 min on two occasions. One second forced expiratory volumes were measured before and at periodic intervals between 30 min and 24 hr after challenge. Venous blood samples were drawn 30 min and 8, 24, 48, and 72 hr after **toluene** diisocyanate. Total and differential leukocyte counts and T-cell subpopulations were determined. The five dual responders demonstrated forced expiratory volume in 1 sec decreased indicative of early and late asthmatic reactions and the five late responders demonstrated forced expiratory volume in 1 second decr indicative of a late asthmatic reaction. **Toluene** diisocyanate challenge did not affect the number of circulating erythrocytes and leukocytes. The percentage of eosinophils was significantly increased 24 hr after challenge and sustained for up to 48 hr. The percentages of neutrophils, lymphocytes, and monocytes were not altered by **toluene** diisocyanate. Among the T-lymphocyte subpopulation, the proportion of CD8(+) lymphocytes was significantly increased 8 hr after **toluene** diisocyanate challenge. The increase was more pronounced in the lat responders. An additional increase in CD8(+) lymphocytes occurred 48 hr post exposure in seven subjects but was unrelated to responder type. The number of CD4(+) cells did not change. This resulted in a decrease in the CD4(+)/CD8(+) ratio 8 and 48 hr after **toluene** diisocyanate challenge. It was concluded that **toluene** diisocyanate induced late asthmatic reactions are associated with an increase in the number of suppressor/cytotoxic lymphocytes and eosinophils in peripheral blood.
[Finotto S et al; Br J Ind Med 48 (2):116-21 (1991)]**PEER REVIEWED**

Intravenously administered endotoxin inhibits the polymorphonuclear leukocyte dependent airway edema produced in guinea pigs exposed to **toluene** diisocyanate. Tumor necrosis factor is produced in

vivo by peripheral blood monocytes and tissue macrophages stimulated with endotoxin and has been shown to activate polymorphonuclear leukocyte's and vascular endothelial cells. To determine whether the inhibition of airway edema is mediated by tumor necrosis factor, guinea pigs were treated with intravenous saline or 75,000 U/kg recombinant human tumor necrosis factor 1.5 hr before exposure to air or 3 ppm **toluene** diisocyanate for 1 hr. Animals were then injected intravenously with 50 mg/kg Evans blue dye as a marker of protein extravasation. Saline-treated animals exposed to **toluene** diisocyanate had a significant increase in tracheal Evans blue dye extravasation (85 + or - 6.5 ug dye/g trachea, mean + or - standard error) compared with saline-treated animals exposed to air (31.3 + or - 2.5, $P < 0.001$). The tracheal extravasation of Evans blue dye was significantly inhibited ($P < 0.05$) in **toluene** diisocyanate exposed animals treated with tumor necrosis factor (64.7 + or - 7.5). Neither heat-inactivated tumor necrosis factor (104.9 + or - 9.5) nor tumor necrosis factor neutralized with a monoclonal antibody against tumor necrosis factor (99.7 + or - 17.9) inhibited **toluene** diisocyanate induced airway edema. In addition, treatment with 15,000 U/kg (99.9 + or - 21.3) or 150,000 U/kg (103.2 + or - 17.6) interleukin 1, a monokine also produced in response to endotoxin, did not prevent airway edema. These results suggest that tumor necrosis factor released in response to endotoxin mediates endotoxin's inhibition of a polymorphonuclear leukocyte dependent airway edema.
[Gordon T, Sheppard D; J Appl Physiol 64 (4): 1988 1688-92]**PEER REVIEWED**

Serum immunoglobulin-G and immunoglobulin-E to isocyanate haptenized human serum albumin (HSA) were estimated by ELISA in 55 isocyanate workers who underwent isocyanate inhalation challenge studies in Montreal, Canada. The challenges were negative in 29 workers and positive in 26 workers. Isocyanate antibodies were estimated by ELISA index. The mean immunoglobulin-G indices were found to be significantly higher in the challenge-positive workers, and there was a similar trend for the immunoglobulin-E indices. Antibody specificities for **toluene** diisocyanate-human serum albumin, diphenylmethane diisocyanate-human serum albumin, and hexamethylene diisocyanate-human serum albumin were determined by inhibition studies with a variety of isocyanate haptenized carriers. The other isocyanate substituted carriers were either noninhibitory or caused only partial inhibition as contrasted with the complete inhibition achieved by human serum albumin conjugated to the isocyanate to which the worker was exposed. We interpret these specificity studies as indicating that the inhalation of isocyanates results in production of antibody that recognizes new antigenic determinants that develop from the coupling of isocyanates to homologous proteins.
[Grammer LC et al; J Allergy Clin Immunol 86 (1): 94-8 (1990)]**PEER REVIEWED**

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concn ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concn of tolyl group after 72 hr and persists at a nanomolar level even 2 wk following the exposure. The initial rate of (14)C uptake is also a linear function of the concn of **toluene** diisocyanate when expressed either as concn (ppm) or as concn multiplied by duration of exposure (ppm.hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm.hr. Finally, the inclusion of the data on methyl isocyanate indicates that the uptake into arterial blood is a function of

exposure concn, independent of isocyanate structure.
[Kennedy AL et al; Toxicol Appl Pharmacol 100 (2): 280-92 (1989)]**PEER REVIEWED**

Isocyanates are an important cause of occupational asthma. The mechanism of isocyanate induced asthma is still unknown. To determine whether **toluene** diisocyanate stimulates the 'efferent' function of peripheral endings of capsaicin-sensitive sensory nerves, we investigated the effect of **toluene** diisocyanate in the rat isolated urinary bladder, a preparation in which the action of capsaicin has been well characterized. **Toluene** diisocyanate (0.03 mM) produced a concn dependent contraction of the bladder strips. It maximal effect was about 50 % of the response to capsaicin (1 uM). Previous exposure of the strips to capsaicin followed by washing out produced complete unresponsiveness, both to the first exposure to **toluene** diisocyanate and to a second exposure of capsaicin. Further, the response to both **toluene** diisocyanate and capsaicin was completely prevented by extrinsic bladder denervation, achieved by bilateral removal of pelvic ganglia (72 hr before). Repeated exposure of the rat bladder to **toluene** diisocyanate reduced the capsaicin-evoked release of calcitonin gene-related peptide like immunoreactivity (CGRP-LI), taken as biochemical marker of activation of these sensory nerves. These experiments provide the first evidence that **toluene** diisocyanate activates directly or indirectly the efferent function of capsaicin-sensitive primary sensory nerves.
[Mapp CE et al; Eur J Pharmacol 180 (1): 113-8 (1990)]**PEER REVIEWED**

The in vivo exposure to an asthmogenic stimulus, **toluene** diisocyanate, causes airway epithelial damage associated with inflammation and increased bronchial hyperresponsiveness. The latter mechanisms might partly be mediated by the release of eicosanoids from bronchial epithelial cells. Previously it has been demonstrated that the in vitro exposure of bronchial epithelial cells to **toluene** diisocyanate results in the release of immunoreactive 15-hydroxyeicosatetraenoic acid, a product of activation of the 15-lipoxygenase pathway with inflammatory properties. Present study shows that **toluene** diisocyanate induced release of 15-hydroxyeicosatetraenoic acid from epithelial cells can be prevented by nedocromil sodium, an anti-asthmatic drug with anti-inflammatory properties. This mode of action of the compound may explain its clinical effectiveness in asthma.
[Mattoli S et al; Int Arch Allergy Appl Immunol 92 (1): 16-22 (1990)]**PEER REVIEWED**

To determine whether early and/or late asthmatic responses induced by **toluene** diisocyanate are caused by a reflex mechanism involving stimulation of muscarinic receptors, we studied the effect of the muscarinic antagonist atropine on early and late airway response induced by **toluene** diisocyanate. A preliminary study was conducted in asthmatics to assess whether the selected dose of atropine provided adequate muscarinic blockade. On different days we measured the provocation dose (in mg) of carbachol causing a 15% decrease in forced expiratory volume in 1 second (PD15FEV1) without and with atropine premedication (0.008 or 0.012 mg/kg sc atropine 30 or 90 min before carbachol challenge test). 0.008 to 0.012 mg/kg sc atropine increased the PD15FEV1 carbachol by 6 to 10 fold, inducing a consistent and prolonged decrease in nonspecific bronchial hyperresponsiveness to cholinergic agent. 10 Subjects with a history of sensitization to **toluene** diisocyanate were then examined in 2 sets of experiments. In the first set of experiments, the subjects were studied before and after exposure to **toluene** diisocyanate (0.04 ppm; 30 min) after no treatment. In the second set of experiments, carried out 1 to 2 wk later, the same procedure was repeated after treatment with atropine (0.008 to 0.012 mg/kg atropine sulfate administered sc 30 min before **toluene** diisocyanate challenge, and then at 90 min intervals after **toluene** diisocyanate

exposure); all patients showed symptoms of atropine effect (dryness of mouth, cycloplegia, increased heart rate).
[Paggiaro P et al; Am Rev Respir Dis 136 (5): 1237-41 (1987)]**PEER REVIEWED**

Light and electron microscopic structure of lobar bronchial biopsies were examined of nine subjects with occupational asthma induced by **toluene** diisocyanate and of four control nonasthmatic subjects who had never been exposed to **toluene** diisocyanate. Inflammatory cell numbers were separately assessed in the intact epithelium, in the more superficial layer of the submucosa, and in the total submucosa. Asthmatic subjects had an increased number of inflammatory cells in the airway mucosa compared with control subjects. Eosinophils were significantly increased in all compartments, CD45-positive cells were significantly increased in the epithelium and in the more superficial layer of the submucosa, and mast cells were significantly increased only in epithelium. By electron microscopy eosinophils and mast cells appeare degranulated only in asthmatic patients. In the areas of epithelium that appeared intact by light microscopy, electron microscopy showed that, although the intercellular spaces between columnar cells were similar in asthmatic and control groups, the intercellular spaces between basal cells were significantly wider in patients with asthma. Patients with **toluene** diisocyanate induced asthma also had a thicker subepithelial reticular layer, where immunohistochemistry showed the presence of collagen III. In conclusion, in patients with asthma induced by **toluene** diisocyanate, the airway mucosa shows pathologic features, such as inflammatory cell infiltrate and thickening of subepithelial collagen, similar to those described in atopic asthma.
[Saetta M et al; Am Rev Respir Dis 145 (1): 160-8 (1992)]**PEER REVIEWED**

Serum neutrophil chemotactic activity, which is associated with mast cell or basophil activation, was quantitated to determine if mast cell or basophil mediators are released during bronchoprovocation-inhalation challenge with subirritant levels of **toluene** diisocyanate. Four subjects with suspected **toluene** diisocyanate induced asthma and four mite-sensitive subjects with asthma who served as a comparison group were studied. neutrophil chemotactic activity was measured in a multiwell, microchemotaxis chamber. Blood samples were collected, and forced expiratory volume in 1 second measurements were performed before challenge and at regular intervals during the subsequent 24 hr. Three of four workers clinically sensitive to **toluene** diisocyanate reacted to a subirritant **toluene** diisocyanate exposure. There was no increase in neutrophil chemotactic activity during placebo challenges. neutrophil chemotactic activity increased in the three **toluene** diisocyanate sensitive workers during early and late asthmatic reactions in quantities proportional to the forced expiratory volume in 1 second decline. No increase in neutrophil chemotactic activity was found during **toluene** diisocyanate exposures in the **toluene** diisocyanate negative worker. Gel filtration analysis demonstrated the main neutrophil chemotactic activity fraction eluted with macromolecules of an estimated molecular weight greater than 440,000 daltons. This characteristic is compatible with neutrophil chemotactic factor of basophil or mast cell origin. The kinetics of neutrophil chemotactic activity release were similar in mite- and **toluene** diisocyanate induced asthmatic reactions. A high correlation ($r = 0.97$; $p = 0.0006$) was obtained between the percent decrease in forced expiratory volume in 1 second during early asthmatic reactions and percent increase in neutrophil chemotactic activity. These observations support the hypothesis that activation of mast cells or basophils is associated with **toluene** diisocyanate induced early and late asthmatic reaction.
[Sastre J et al; J Allergy Clin Immunol 85 (3): 567-72 (1990)]**PEER

REVIEWED**

In order to determine whether treatment with ketotifen inhibits asthmatic reactions induced by **toluene** di-isocyanate, six sensitized subjects with previously demonstrated dual or late asthmatic reaction after inhalation challenge with **toluene** diisocyanate were studied. Ketotifen (1 mg bid, orally) or placebo was administered for 7 days to the examined subjects, according to a double-blind, cross-over, placebo controlled study design. When the subjects were treated with either ketotifen or placebo, forced expiratory volume in 1 second markedly decr after exposure to **toluene** diisocyanate. These results suggest that the anti-asthmatic agent ketotifen is not effective in **toluene** diisocyanate induced asthma and suggest that it should not be used in the prophylaxis of asthmatic reactions induced by **toluene** diisocyanate in sensitized subjects.
[Tossin L et al; Clin Exp Allergy 19 (2): 177-82 (1989)]**PEER REVIEWED**

The beta-adrenoceptors on intact peripheral blood lymphocytes were studied in 21 allergic asthmatics, 11 **toluene** diisocyanate asthmatics and 17 normal subjects with radioligand binding assay technique. The airway responsiveness to methacholine provocation test was determined. The results indicated that beta-adrenoceptor Bmax values in allergic and **toluene** diisocyanate asthmatics were reduced but the affinity between receptor and ligand was increased; there was a positive correlation between the values of Bmax and forced expiratory volume in 1 second%, V25/Pr in both asthmatic groups, a positive correlation between the values of Bmax and PC20 in allergic asthmatics. The beta-adrenoceptor responsiveness was remarkably reduced in allergic asthmatics.
[Yang ZF et al; Chin J Tuberc Respir Dis 12 (3): 143-146, 190-191. (1989)]**PEER REVIEWED**

Leukotriene B4 release from the lungs of sensitized subjects during asthmatic reactions induced by **toluene** diisocyanate was investigated. Three groups of **toluene** diisocyanate sensitized subjects were examined, one after no exposure to **toluene** diisocyanate, the second 8 hr after an exposure to **toluene** diisocyanate that caused an early asthmatic reaction, and the third 8 hr after an exposure to **toluene** diisocyanate that caused a late asthmatic reaction. Bronchoalveolar lavage fluid was analysed by reverse-phase HPLC and by specific radioimmunoassay. The mean concn of leukotriene B4 was higher (0.31 + or - 0.09 (standard error) ng/ml, range 0.15-0.51) in bronchoalveolar lavage fluid of sensitized subjects who developed a late asthmatic reaction than in bronchoalveolar lavage fluid of subjects who developed an early asthmatic reaction (0.05 + or - 0.04 ng/ml, range 0-0.224), and no leukotriene B4 was detectable in the control subjects. Bronchoalveolar lavage was also performed 8 hr after **toluene** diisocyanate exposure on four **toluene** diisocyanate sensitized late-dual reactors who were on steroid treatment. In this group of subjects no leukotriene B4 was detectable. These results suggest that leukotriene B4 may be involved in late asthmatic reactions induced by **toluene** diisocyanate.

Interactions:

The effects of methacholine inhalation on airway responsiveness in **toluene** diisocyanate induced asthma were studied in six workers with a history of sensitivity to **toluene** diisocyanate. Symptoms among subjects included shortness of breath, wheezing, cough, and chest tightness at work, during the evening, or at night. A detailed cllnical and occupational history was taken for each subject, and lung function measurement and skin intradermal tests for common allergens were conducted. Airway responsiveness to

methacholine was assessed before subjects were exposed for 30 minutes to 0.02 part per million **toluene** diisocyanate in an exposure chamber. Eight hours after **toluene** diisocyanate inhalation, airway responsiveness to methacholine was again determined. Forced expiratory volume was the measure of airway responsiveness. Although methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, the challenge went into the asthmatic range after **toluene** diisocyanate inhalation. Airway responsiveness increased significantly 8 hours after **toluene** diisocyanate challenge in the subjects and was accompanied by a decrease in forced expiratory volume. The late asthmatic reaction began between 3 and 5 hours asthma can be induced by **toluene** diisocyanate in the absence of airway responsiveness.

Metabolism/Metabolites:

A technique for detectingurinary amine metabolites in rats exposed to **toluene** diisocyanate was evaluated. Skin tissue of rats was exposed to 40% **toluene**-2,4-diisocyanate solution in di-n-butyl-ether liquid. Rats were exposed daily for 3 hr on 4 consecutive days. Urine was collected in metabolic cages for 18 hr after the last exposure. Chromatographic techniques were used for nitrogen selective detection of nonderivatized amines. An autolinear temperature programmer was employed to analyze derivatized amine. The identity of the amine was confirmed by gas chromatography/mass spectrometry. A linear correlation was found between **toluene**-2,4-diamine added to urine and peak height. Peak height and recovery from the non hydrolyzed and from the hydrolyzed urine was about 85 and 70%, respectively. No free **toluene**-2,4-diamine or free **toluene**-2,4-diisocyanate was detected in the urine of rats exposed to **toluene**-2,4-diamine in hydrolyzed urine was 1.5 micrograms per milliliter. Gas chromatography/mass spectrometry confirmed the identity of the amine. /This/ highly sensitive technique tested is easy to apply and is effective for trace assays of amines.
[Rosenberg C; J Chromatography 323 (2): 429-33 (1985)]**PEER REVIEWED**

Epithelial injury and inflammation are involved in airway hyperresponsiveness and asthma induced by **toluene** diisocyanate. In that isocyanates are insoluble and highly reactive compounds, bronchial epithelial cells may represent the most important target cells of their toxic effect. We hypothesized that damage to airway epithelium by **toluene** diisocyanate may result in the release of metabolites of arachidonic acid, which are known to promote inflammation and to alter epithelial cell function and airway smooth muscle responsiveness. To test this hypothesis we examined eicosanoid products in the culture media of bronchial epithelial cells exposed in vitro to 8 and 18 ppb **toluene** diisocyanate. Epithelial cells derived from human bronchi obtained at surgery were cultured to confluency on collagen-coated microporous membranes. Those cells, which expressed differentiated characteristics of epithelial cells (they showed keratin-containing filaments and had a cobblestone appearance), were alternatively exposed to **toluene** diisocyanate or air for 30 min in a specially designed in vitro chamber. The production of metabolites of arachidonic acid was assessed by measuring the release of immunoreactive products into the cell medium at the end of the exposure and during a 2 hr period after exposure. This method revealed a predominant isocyanate induced release of immunoreactive 15-hydroxyeicosatetraenoic acid. Release rate of this compound tended to be dose-related and was associated with cell damage as assessed by the release of lactate dehydrogenase in the medium.
[Mattoli S et al; J Cell Physiol 142 (2): 379-85 (1990)]**PEER REVIEWED**

It has been previously shown that tachykinin depletion or antagonism prevented the increase in airway responsiveness to inhaled acetylcholine caused by exposure to **toluene** diisocyanate in awake guinea pigs. To insure that the effects of tachykinins were not limited to the extrathoracic airways and were not dependent on effects of **toluene** diisocyanate on baseline airway caliber, airway responsiveness to acetylcholine inhaled through tracheostomy in anesthetized and ventilated guinea pigs that were exposed to **toluene** diisocyanate or air after treatment with the tachykinin antagonist spantide, the tachykinin metabolism inhibitor phosphoramidon, or the vehicles for each drug were determined. When these drugs

were administered before and during **toluene** diisocyanate exposure, spantide significantly inhibited the **toluene** diisocyanate induced increase in acetylcholine responsiveness and phosphoramidon significantly potentiated this effect, whereas neither drug altered acetylcholine responsiveness in air exposed animals. To determine whether tachykinins were exerting their effect primarily during **toluene** diisocyanate exposure or during the subsequent acetylcholine challenge, the effect of each drug on acetylcholine responsiveness was also examined when the drugs were given after **toluene** diisocyanate exposure. At that time, spantide did not inhibit **toluene** diisocyanate induced acetylcholine hyperresponsiveness and phosphoramidon did not potentiate it. Neither drug nor **toluene** diisocyanate increased pulmonary resistance measured through a tracheostomy in these anesthetized and ventilated animals. These results suggest that the **toluene** diisocyanate induced increase in acetylcholine responsiveness is mediated by release of tachykinins into the intrathoracic airways during exposure to **toluene** diisocyanate.
[Sheppard D, Scypinski L; Am Rev Respir Dis 138 (3): 547-51 (1988)]**PEER REVIEWED**

Five men were exposed to **toluene** diisocyanate atmospheres for 7.5 hr. The **toluene** diisocyanate atmospheres were generated by a gas-phase permeation method, and the exposures were performed in an 8 cu m stainless steel test chamber. The mean air concn of **toluene** diisocyanate was ca 40 ug/cu m, which corresponds to the TLV of Sweden. The inhaled doses of 2,4- and 2,6-**toluene** diisocyanate were ca 120 ug. **Toluene** diisocyanate in the test chamber air was determined by an HPLC method using the 9-(N-methylaminomethyl)-anthracene reagent and by a continuous monitoring filter-tape instrument. After hydrolysis of plasma and urine, the related amines, 2,4- and 2,6-toluenediamine 2,4-, and 2,6-TDA), were determined as pentafluoropropionic anhydride derivatives by capillary gas-chromatography using selected ion monitoring in the electron-impact mode. The urinary elimination of the toluenediamines showed a possible biphasic pattern, with rapid first phases for 2,4-toluenediamine (mean half-life for the concn in urine, 1.9 hr) and for 2,6-toluenediamine (mean half-life for the concn in urine, 1.6 hr). The cumulative amount of 2,4-toluenediamine excreted in urine within 28 hr ranged from 8% to 14% of the estimated dose of 2,4-**toluene** diisocyanate, and the cumulative amount of 2,6-toluenediamine in urine ranged from 14% to 18% of the 2,6-**toluene** diisocyanate dose. The average urinary level of 2,4-toluenediamine was 5 ug/l in the 6 to 8 hr sample (range 2.8-9.6 ug/l), and the corresponding value fo 2,6-toluenediamine was 8.6 ug/l (range, 5.6-16.6 ug/l). Biological monitoring of exposure to 2,4- and 2,6-**toluene** diisocyanate by analysis of 2,4- and 2,6-toluenediamine in urine is feasible.

Mechanism of Action:

SERUM FROM 26 PERSONS SHOWN TO REACT TO PROVOCATIVE INHALATION CHALLENGE WITH LOW CONCN OF **TOLUENE** DIISOCYANATE WAS TESTED BY RADIOALLERGOSORBENT TEST (RAST) USING A P-TOLYL ISOCYANATE-HUMAN SERUM ALBUMIN (TMI-HSA) CONJUGATE. POSITIVE RESULTS WERE OBTAINED IN 15-19% OF **TOLUENE** DIISOCYANATE REACTORS, DEPENDING ON THE METHOD OF EVALUTION. **TOLUENE** DIISOCYANATE ASTHMA MAY BE A COMPLEX SYNDROME WITH SEVERAL TYPES OF REACTIONS POSSIBLE, INCLUDING AN IMMUNOGLOBULIN-E MECHANISM IN SOME INDIVIDUALS. THE THEORY THAT **TOLUENE** DIISOCYANATE ASTHMA IS BASED SOLELY ON AN IMMUNE MECHANISM IS NOT SUPPORTED. THE FINDINGS DO NOT DISAGREE WITH THE HYPOTHESIS THAT **TOLUENE** DIISOCYANATE REACTIVITY MAY BE MEDIATED BY A PHARMACOLOGIC MECHANISM.
[BUTCHER BT ET AL; J ALLERGY CLIN IMMUNOL 66 (3): 213 (1980)]**PEER REVIEWED**

To investigate the role of pharmacological mechanisms in **toluene** diisocyanate induced occupational asthma, the effects of **toluene** diisocyanate on rat trachea ring and lung parenchymal strip were studied in vitro. The most prominent effect observed was a stimulation of metacholine induced contraction of the tracheal ring by 1M **toluene** diisocyanate (added in dimethyl sulfoxide). The results were less pronounced when **toluene** diisocyanate was added from a stock solution prepared in water, which is possibly due to copolymerisation. It is concluded that the pharmacological effect of **toluene** diisocyanate may result from an autonomic imbalance between cholinergic and B-adrenergic neural control.
[Borm PJA et al; Br J Ind Med 46 (1): 56-9 (1989)]**PEER REVIEWED**

A study of the occurrence of serum immunoglobulin-E and immunoglobulin-G antibodies in workers with isocyanate induced asthma was conducted. The study group consisted of 62 workers (58 males) being evaluated for occupational asthma. Thirty nine had been exposed to hexamethylene diisocyanate, 17 to diphenylmethane diisocyanate, and six to **toluene** diisocyanate. The subjects completed a respiratory and occupational questionnaire. Spirometric tests were administered. Skin prick tests were performed with 15 common inhalant allergens and **toluene** diisocyanate, hexamethylene diisocyanate, and diphenylmethane diisocyanate human serum albumin conjugates. Blood samples were collected and assayed for specific serum immunoglobulin-G and immunoglobulin-E antibodies to hexamethylene diisocyanate, diphenylmethan diisocyanate, and **toluene** diisocyanate. Specific inhalation challenges were conducted with hexamethylene diisocyanate, diphenylmethane diisocyanate, and **toluene** diisocyanate. Specific inhalation challenge with **toluene** diisocyanate, hexamethylene diisocyanate, or diphenylmethane diisocyanate induced significant bronchoconstriction in half of the subjects, late reactions being the most common. Twenty subjects had significantly elevated immunoglobulin-G concn and nine had significantly elevated immunoglobulin-G plus immunoglobulin-E concn. Six of 12 subjects with elevated immunoglobulin-E and immunoglobulin-G antibodies had positive skin prick tests for hexamethylene diisocyanate and one was sensitized to diphenylmethane diisocyanate. It was concluded that an association between isocyanate specific antibodies and the results of specific inhalation challenge tests has been established. This suggests that isocyanate induced asthma may involve an immunological

mechanism.
[Cartier A et al; J Allergy Clin Immunol 84 (4 Part 1): 507-14 (1989)]**PEER REVIEWED**

The influence of cyclophosphamide induced granulocyte depletion on **toluene** diisocyanate related changes in airway reactivity and pathology was assessed in guinea pigs. Twelve cyclophosphamide-treated and 12 control animals comprising each group were studied physiologically before and 2 hr after a single 10 min exposure to 3 ppm of **toluene** diisocyanate. Reactivity was determined in intact unanesthetized animals by measuring specific airway conductance before and during intravenous acetylcholine infusion. After testing, tracheal tissue for light microscopic examination was obtained from three hyperreactive guinea pigs in each exposed group and compared with tissue from treated and control animals (n = 3 each) that had not been **toluene** diisocyanate exposed. Cyclophosphamide treatment caused substantial decr in both circulating and airway granulocyte counts. However, the incidence and degree of bronchial hyperreactivity that occurred 2 hr post-**toluene** diisocyanate was similar in the untreated and treated groups. Results indicate that **toluene** diisocyanate induced bronchial hyperreactivity 1) occurs shortly after a brief high concn exposure and 2) appears independent of circulating or airway granulocyte counts.
[Cibulas W Jr et al; J Appl Physiol 64 (5): 1773-8 (1988)]**PEER REVIEWED**

To determine the importance of airway inflammation for the development of late asthmatic reactions, we examined sensitized subjects during late asthmatic reactions induced by exposure to **toluene** diisocyanate in the laboratory. Late asthmatic reactions are associated with a transient increase of bronchial responsiveness and, at the same time, with an increase of neutrophils followed by eosinophils, and of leukotriene B4 and albumin in bronchoalveolar lavage fluid. Late asthmatic reactions, increased bronchial responsiveness, and increase of neutrophils, eosinophils, leukotriene B4, and albumin concn in bronchoalveolar lavage induced by exposure to **toluene** diisocyanate are all prevented by pretreatment with prednisone but not with the nonsteroidal anti-inflammatory agent indomethacin. Aerosolized steroids (beclomethasone and dexamethasone isonicotinate) completely inhibit late asthmatic reactions induced by **toluene** diisocyanate, whereas theophylline has a partial, and verapamil, ketotifen, and cromolyn have no protective effect. These results suggest that late asthmatic reactions induced by **toluene** diisocyanate may be caused by airway inflammation, and that anti-inflammatory steroids should be recommended in the prophylaxis of **toluene** diisocyanate asthma.
[Fabbri LM et al; Am Rev Respir Dis 143 (3 Pt 2): 537-8 (1991)]**PEER REVIEWED**

The effects of **toluene** diisocyanate on T-cell subpopulations and circulating lymphocytes in ten persons (five males)): 19 to 50 yr old, with **toluene** diisocyanate induced occupational asthma were examined. Five subjects revealed early and late asthmatic reactions to **toluene** diisocyanate (dual responders) and five revealed late asthmatic reactions (late responders). Subjects underwent inhalation challenge with 0.005 to 0.015 ppm **toluene** diisocyanate or filtered air for 10 to 30 min on two occasions. One second forced expiratory volumes were measured before and at periodic intervals between 30 min and 24 hr after challenge. Venous blood samples were drawn 30 min and 8, 24, 48, and 72 hr after **toluene** diisocyanate. Total and differential leukocyte counts and T-cell subpopulations were determined. The five dual responders demonstrated forced expiratory volume in 1 sec decreased indicative of early and late asthmatic reactions and the five late responders demonstrated forced expiratory volume in 1 second decr indicative of a late asthmatic reaction. **Toluene** diisocyanate challenge did not affect the number of

circulating erythrocytes and leukocytes. The percentage of eosinophils was significantly increased 24 hr after challenge and sustained for up to 48 hr. The percentages of neutrophils, lymphocytes, and monocytes were not altered by **toluene** diisocyanate. Among the T-lymphocyte subpopulation, the proportion of CD8(+) lymphocytes was significantly increased 8 hr after **toluene** diisocyanate challenge. The increase was more pronounced in the lat responders. An additional increase in CD8(+) lymphocytes occurred 48 hr post exposure in seven subjects but was unrelated to responder type. The number of CD4(+) cells did not change. This resulted in a decrease in the CD4(+)/CD8(+) ratio 8 and 48 hr after **toluene** diisocyanate challenge. It was concluded that **toluene** diisocyanate induced late asthmatic reactions are associated with an increase in the number of suppressor/cytotoxic lymphocytes and eosinophils in peripheral blood.
[Finotto S et al; Br J Ind Med 48 (2):116-21 (1991)]**PEER REVIEWED**

Intravenously administered endotoxin inhibits the polymorphonuclear leukocyte dependent airway edema produced in guinea pigs exposed to **toluene** diisocyanate. Tumor necrosis factor is produced in vivo by peripheral blood monocytes and tissue macrophages stimulated with endotoxin and has been shown to activate polymorphonuclear leukocyte's and vascular endothelial cells. To determine whether the inhibition of airway edema is mediated by tumor necrosis factor, guinea pigs were treated with intravenous saline or 75,000 U/kg recombinant human tumor necrosis factor 1.5 hr before exposure to air or 3 ppm **toluene** diisocyanate for 1 hr. Animals were then injected intravenously with 50 mg/kg Evans blue dye as a marker of protein extravasation. Saline-treated animals exposed to **toluene** diisocyanate had a significant increase in tracheal Evans blue dye extravasation (85 + or - 6.5 ug dye/g trachea, mean + or - standard error) compared with saline-treated animals exposed to air (31.3 + or - 2.5, $P < 0.001$). The tracheal extravasation of Evans blue dye was significantly inhibited ($P < 0.05$) in **toluene** diisocyanate exposed animals treated with tumor necrosis factor (64.7 + or - 7.5). Neither heat-inactivated tumor necrosis factor (104.9 + or - 9.5) nor tumor necrosis factor neutralized with a monoclonal antibody against tumor necrosis factor (99.7 + or - 17.9) inhibited **toluene** diisocyanate induced airway edema. In addition, treatment with 15,000 U/kg (99.9 + or - 21.3) or 150,000 U/kg (103.2 + or - 17.6) interleukin 1, a monokine also produced in response to endotoxin, did not prevent airway edema. These results suggest that tumor necrosis factor released in response to endotoxin mediates endotoxin's inhibition of a polymorphonuclear leukocyte dependent airway edema.
[Gordon T, Sheppard D; J Appl Physiol 64 (4): 1988 1688-92]**PEER REVIEWED**

Serum immunoglobulin-G and immunoglobulin-E to isocyanate haptenized human serum albumin (HSA) were estimated by ELISA in 55 isocyanate workers who underwent isocyanate inhalation challenge studies in Montreal, Canada. The challenges were negative in 29 workers and positive in 26 workers. Isocyanate antibodies were estimated by ELISA index. The mean immunoglobulin-G indices were found to be significantly higher in the challenge-positive workers, and there was a similar trend for the immunoglobulin-E indices. Antibody specificities for **toluene** diisocyanate-human serum albumin, diphenylmethane diisocyanate-human serum albumin, and hexamethylene diisocyanate-human serum albumin were determined by inhibition studies with a variety of isocyanate haptenized carriers. The other isocyanate substituted carriers were either noninhibitory or caused only partial inhibition as contrasted with the complete inhibition achieved by human serum albumin conjugated to the isocyanate to which the worker was exposed. We interpret these specificity studies as indicating that the inhalation of isocyanates results in production of antibody that recognizes new antigenic determinants that develop from the coupling of isocyanates to homologous proteins.

[Grammer LC et al; J Allergy Clin Immunol 86 (1): 94-8 (1990)]**PEER REVIEWED**

Inhalation of **toluene** diisocyanate results in toxic responses ranging from pulmonary irritation to immunological sensitization. The use of radioactively labeled isocyanate has made it possible to follow the initial uptake of the compound into the bloodstream independent of the final fate of the isocyanate. This study shows that the rate of uptake into the blood is linear during exposure to concn ranging from 0.00005 to 0.146 ppm and that the uptake continues to increase slightly postexposure. It also demonstrates that the radioactivity clears from the bloodstream to a level corresponding to approximately a 100 nM concn of tolyl group after 72 hr and persists at a nanomolar level even 2 wk following the exposure. The initial rate of (14)C uptake is also a linear function of the concn of **toluene** diisocyanate when expressed either as concn (ppm) or as concn multiplied by duration of exposure (ppm.hr). This is discussed in comparison with the toxic responses as a function of both ppm and ppm.hr. Finally, the inclusion of the data on methyl isocyanate indicates that the uptake into arterial blood is a function of exposure concn, independent of isocyanate structure.
[Kennedy AL et al; Toxicol Appl Pharmacol 100 (2): 280-92 (1989)]**PEER REVIEWED**

Isocyanates are an important cause of occupational asthma. The mechanism of isocyanate induced asthma is still unknown. To determine whether **toluene** diisocyanate stimulates the 'efferent' function of peripheral endings of capsaicin-sensitive sensory nerves, we investigated the effect of **toluene** diisocyanate in the rat isolated urinary bladder, a preparation in which the action of capsaicin has been well characterized. **Toluene** diisocyanate (0.03 mM) produced a concn dependent contraction of the bladder strips. It maximal effect was about 50 % of the response to capsaicin (1 uM). Previous exposure of the strips to capsaicin followed by washing out produced complete unresponsiveness, both to the first exposure to **toluene** diisocyanate and to a second exposure of capsaicin. Further, the response to both **toluene** diisocyanate and capsaicin was completely prevented by extrinsic bladder denervation, achieved by bilateral removal of pelvic ganglia (72 hr before). Repeated exposure of the rat bladder to **toluene** diisocyanate reduced the capsaicin-evoked release of calcitonin gene-related peptide like immunoreactivity (CGRP-LI), taken as biochemical marker of activation of these sensory nerves. These experiments provide the first evidence that **toluene** diisocyanate activates directly or indirectly the efferent function of capsaicin-sensitive primary sensory nerves.
[Mapp CE et al; Eur J Pharmacol 180 (1): 113-8 (1990)]**PEER REVIEWED**

The in vivo exposure to an asthmogenic stimulus, **toluene** diisocyanate, causes airway epithelial damage associated with inflammation and increased bronchial hyperresponsiveness. The latter mechanisms might partly be mediated by the release of eicosanoids from bronchial epithelial cells. Previously it has been demonstrated that the in vitro exposure of bronchial epithelial cells to **toluene** diisocyanate results in the release of immunoreactive 15-hydroxyeicosatetraenoic acid, a product of activation of the 15-lipoxygenase pathway with inflammatory properties. Present study shows that **toluene** diisocyanate induced release of 15-hydroxyeicosatetraenoic acid from epithelial cells can be prevented by nedocromil sodium, an anti-asthmatic drug with anti-inflammatory properties. This mode of action of the compound may explain its clinical effectiveness in asthma.
[Mattoli S et al; Int Arch Allergy Appl Immunol 92 (1): 16-22 (1990)]**PEER REVIEWED**

To determine whether early and/or late asthmatic responses induced by **toluene** diisocyanate are caused by a reflex mechanism involving stimulation of muscarinic receptors, we studied the effect of the muscarinic antagonist atropine on early and late airway response induced by **toluene** diisocyanate. A preliminary study was conducted in asthmatics to assess whether the selected dose of atropine provided adequate muscarinic blockade. On different days we measured the provocation dose (in mg) of carbachol causing a 15% decrease in forced expiratory volume in 1 second (PD15FEV1) without and with atropine premedication (0.008 or 0.012 mg/kg sc atropine 30 or 90 min before carbachol challenge test). 0.008 to 0.012 mg/kg sc atropine increased the PD15FEV1 carbachol by 6 to 10 fold, inducing a consistent and prolonged decrease in nonspecific bronchial hyperresponsiveness to cholinergic agent. 10 Subjects with a history of sensitization to **toluene** diisocyanate were then examined in 2 sets of experiments. In the first set of experiments, the subjects were studied before and after exposure to **toluene** diisocyanate (0.04 ppm; 30 min) after no treatment. In the second set of experiments, carried out 1 to 2 wk later, the same procedure was repeated after treatment with atropine (0.008 to 0.012 mg/kg atropine sulfate administered sc 30 min before **toluene** diisocyanate challenge, and then at 90 min intervals after **toluene** diisocyanate exposure); all patients showed symptoms of atropine effect (dryness of mouth, cycloplegia, increased heart rate).
[Paggiaro P et al; Am Rev Respir Dis 136 (5): 1237-41 (1987)]**PEER REVIEWED**

Light and electron microscopic structure of lobar bronchial biopsies were examined of nine subjects with occupational asthma induced by **toluene** diisocyanate and of four control nonasthmatic subjects who had never been exposed to **toluene** diisocyanate. Inflammatory cell numbers were separately assessed in the intact epithelium, in the more superficial layer of the submucosa, and in the total submucosa. Asthmatic subjects had an increased number of inflammatory cells in the airway mucosa compared with control subjects. Eosinophils were significantly increased in all compartments, CD45-positive cells were significantly increased in the epithelium and in the more superficial layer of the submucosa, and mast cells were significantly increased only in epithelium. By electron microscopy eosinophils and mast cells appeare degranulated only in asthmatic patients. In the areas of epithelium that appeared intact by light microscopy, electron microscopy showed that, although the intercellular spaces between columnar cells were similar in asthmatic and control groups, the intercellular spaces between basal cells were significantly wider in patients with asthma. Patients with **toluene** diisocyanate induced asthma also had a thicker subepithelial reticular layer, where immunohistochemistry showed the presence of collagen III. In conclusion, in patients with asthma induced by **toluene** diisocyanate, the airway mucosa shows pathologic features, such as inflammatory cell infiltrate and thickening of subepithelial collagen, similar to those described in atopic asthma.
[Saetta M et al; Am Rev Respir Dis 145 (1): 160-8 (1992)]**PEER REVIEWED**

Serum neutrophil chemotactic activity, which is associated with mast cell or basophil activation, was quantitated to determine if mast cell or basophil mediators are released during bronchoprovocation-inhalation challenge with subirritant levels of **toluene** diisocyanate. Four subjects with suspected **toluene** diisocyanate induced asthma and four mite-sensitive subjects with asthma who served as a comparison group were studied. neutrophil chemotactic activity was measured in a multiwell, microchemotaxis chamber. Blood samples were collected, and forced expiratory volume in 1 second measurements were performed before challenge and at regular intervals during the subsequent 24 hr. Three of four workers clinically sensitive to **toluene** diisocyanate reacted to a subirritant **toluene**

diisocyanate exposure. There was no increase in neutrophil chemotactic activity during placebo challenges. neutrophil chemotactic activity increased in the three **toluene** diisocyanate sensitive workers during early and late asthmatic reactions in quantities proportional to the forced expiratory volume in 1 second decline. No increase in neutrophil chemotactic activity was found during **toluene** diisocyanate exposures in the **toluene** diisocyanate negative worker. Gel filtration analysis demonstrated the main neutrophil chemotactic activity fraction eluted with macromolecules of an estimated molecular weight greater than 440,000 daltons. This characteristic is compatible with neutrophil chemotactic factor of basophil or mast cell origin. The kinetics of neutrophil chemotactic activity release were similar in mite- and **toluene** diisocyanate induced asthmatic reactions. A high correlation (r = 0.97; p = 0.0006) was obtained between the percent decrease in forced expiratory volume in 1 second during early asthmatic reactions and percent increase in neutrophil chemotactic activity. These observations support the hypothesis that activation of mast cells or basophils is associated with **toluene** diisocyanate induced early and late asthmatic reaction.
[Sastre J et al; J Allergy Clin Immunol 85 (3): 567-72 (1990)]**PEER REVIEWED**

In order to determine whether treatment with ketotifen inhibits asthmatic reactions induced by **toluene** di-isocyanate, six sensitized subjects with previously demonstrated dual or late asthmatic reaction after inhalation challenge with **toluene** diisocyanate were studied. Ketotifen (1 mg bid, orally) or placebo was administered for 7 days to the examined subjects, according to a double-blind, cross-over, placebo controlled study design. When the subjects were treated with either ketotifen or placebo, forced expiratory volume in 1 second markedly decr after exposure to **toluene** diisocyanate. These results suggest that the anti-asthmatic agent ketotifen is not effective in **toluene** diisocyanate induced asthma and suggest that it should not be used in the prophylaxis of asthmatic reactions induced by **toluene** diisocyanate in sensitized subjects.
[Tossin L et al; Clin Exp Allergy 19 (2): 177-82 (1989)]**PEER REVIEWED**

The beta-adrenoceptors on intact peripheral blood lymphocytes were studied in 21 allergic asthmatics, 11 **toluene** diisocyanate asthmatics and 17 normal subjects with radioligand binding assay technique. The airway responsiveness to methacholine provocation test was determined. The results indicated that beta-adrenoceptor Bmax values in allergic and **toluene** diisocyanate asthmatics were reduced but the affinity between receptor and ligand was increased; there was a positive correlation between the values of Bmax and forced expiratory volume in 1 second%, V25/Pr in both asthmatic groups, a positive correlation between the values of Bmax and PC20 in allergic asthmatics. The beta-adrenoceptor responsiveness was remarkably reduced in allergic asthmatics.

Leukotriene B4 release from the lungs of sensitized subjects during asthmatic reactions induced by **toluene** diisocyanate was investigated. Three groups of **toluene** diisocyanate sensitized subjects were examined, one after no exposure to **toluene** diisocyanate, the second 8 hr after an exposure to **toluene** diisocyanate that caused an early asthmatic reaction, and the third 8 hr after an exposure to **toluene** diisocyanate that caused a late asthmatic reaction. Bronchoalveolar lavage fluid was analysed by reverse-phase HPLC and by specific radioimmunoassay. The mean concn of leukotriene B4 was higher (0.31 + or - 0.09 (standard error) ng/ml, range 0.15-0.51) in bronchoalveolar lavage fluid of sensitized subjects who developed a late asthmatic reaction than in bronchoalveolar lavage fluid of subjects who

developed an early asthmatic reaction (0.05 + or - 0.04 ng/ml, range 0-0.224), and no leukotriene B4 was detectable in the control subjects. Bronchoalveolar lavage was also performed 8 hr after **toluene** diisocyanate exposure on four **toluene** diisocyanate sensitized late-dual reactors who were on steroid treatment. In this group of subjects no leukotriene B4 was detectable. These results suggest that leukotriene B4 may be involved in late asthmatic reactions induced by **toluene** diisocyanate.

Pharmacology:

Interactions:

The effects of methacholine inhalation on airway responsiveness in **toluene** diisocyanate induced asthma were studied in six workers with a history of sensitivity to **toluene** diisocyanate. Symptoms among subjects included shortness of breath, wheezing, cough, and chest tightness at work, during the evening, or at night. A detailed cllnical and occupational history was taken for each subject, and lung function measurement and skin intradermal tests for common allergens were conducted. Airway responsiveness to methacholine was assessed before subjects were exposed for 30 minutes to 0.02 part per million **toluene** diisocyanate in an exposure chamber. Eight hours after **toluene** diisocyanate inhalation, airway responsiveness to methacholine was again determined. Forced expiratory volume was the measure of airway responsiveness. Although methacholine challenge was within normal limits when performed before **toluene** diisocyanate inhalation, the challenge went into the asthmatic range after **toluene** diisocyanate inhalation. Airway responsiveness increased significantly 8 hours after **toluene** diisocyanate challenge in the subjects and was accompanied by a decrease in forced expiratory volume. The late asthmatic reaction began between 3 and 5 hours asthma can be induced by **toluene** diisocyanate in the absence of airway responsiveness.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Commercial **toluene** diisocyanate (TDI) is composed of 2 isomers. 2,4-**Toluene** diisocyanate constitutes roughly 80% of TDI, the other 20% being the 2,6-isomer. It may be released to the environment as fugitive emissions and from stack exhaust during the production, transport, and use of TDI in the manufacture of polyurethane foam products and coatings as well as from spills. The types of reactions which the isomers undergo are similar, although the rates may differ. The reactivity of the 2,4-**toluene** diisocyanate with active hydrogen is greater than with the 2,6-isomer, therefore the percentage of 2,4-**toluene** diisocyanate in monitored TDI is generally much less than the 80% in the commercial mixture. However, since much of the monitoring data do not distinguish between isomers, it is not possible to know the proportion of the isomers in the TDI. If spilled on wet land, TDI is rapidly degraded. In one experiment simulating a spill, 5.5% of the original material remained after 24 hours and in a field situation, the concentration of TDI had declined to the ppm levels in 12 weeks. If released into water, a crust forms around the liquid TDI and <0.5% of the original material remains after 35 days. Low concentrations of TDI disappear from the aqueous environment in approximately a day. In the atmosphere, TDI reacts with photochemically produced hydroxyl radicals (half-life 3.3 hr) and is also removed by dry deposition. Human exposure is primarily occupational via inhalation and dermal contact. (SRC)

PEER REVIEWED

Probable Routes of Human Exposure:

Exposure to **toluene** diisocyanate is primarily occupational via inhalation or dermal contact with the aerosol or vapor. Workers may also be exposed through skin contact with freshly cured foam or as a result of spills or splashes. (SRC)

PEER REVIEWED

THE RESPIRATORY HEALTH OF 277 WORKERS IN A NEW **TOLUENE** DIISOCYANATE (TDI) MANUFACTURING PLANT WAS STUDIED PROSPECTIVELY DURING 5 YR OF EXPOSURE. PERSONAL TDI MONITORS WERE USED TO CONTINUOUSLY MEASURE PEAK & 8-HR TIME-WEIGHTED AVG (TWA) CONCN IN MORE THAN 2000 SAMPLES. REGRESSION OF ANNUAL CHANGE ON SMOKING (PACK-YEARS), ATOPIC STATUS & CUMULATIVE TDI EXPOSURE, DICHOTOMIZED AT 68.2 PPB MONTHS INTO LOW & HIGH EXPOSURE GROUPS, SHOWED SIGNIFICANT EFFECTS OF SMOKING ON SPIROMETRIC TESTS & LUNG VOLUMES. AFTER ADJUSTING FOR PACK-YEARS OF SMOKING, THE 74 MEN IN THE HIGH CUMULATIVE TDI EXPOSURE CATEGORY HAD SIGNIFICANTLY LARGER DECLINE IN FEV1 (1-S FORCED EXPIRATORY VOLUME), % FEV (% FORCED EXPIRATORY VOLUME) & FEF25-75% (FORCED EXPIRATORY FRACTION FROM 25 TO 75% VITAL CAPACITY) THAN DID THE 149 MEN IN THE LOW CATEGORY. ANNUAL CHANGE IN FEV1 WAS THEN EXAMINED IN 6 SMOKING-EXPOSURE CATEGORIES: IN NEVER-SMOKERS, AVG ANNUAL DECLINE WAS 38 ML/YR GREATER IN THOSE WITH HIGHER CUMULATIVE TDI

EXPOSURE.

[Hamilton, A., and H. L. Hardy. Industrial Toxicology. 3rd ed. Acton, Mass.: Publishing Sciences Group, Inc., 1974. 335]**PEER REVIEWED**

NIOSH (NOHS Survey 1972-1974) has statistically estimated that 29,284 workers are exposed to TDI in the USA(1). NIOSH (NOES Survey 1981-1983) has statistically estimated that 6,044 workers are exposed to TDI in the USA(2). Since the NOES survey excludes exposure to trade name chemicals which may contain the chemical, occupational exposure could be considerably higher(SRC).
[(1) NIOSH; National Occupational Health Survey (1974) (2) NIOSH; National Occupational Exposure Survey (1983)]**PEER REVIEWED**

Concentration medians for 2,4-**toluene** diisocyanate in 2 plants producing flexible polyurethane foam were 0.70 and 0.33 ppb for the mixing and finishing ends, respectively(1). The respective median values for 2,6-TDI were 0.91 and 1.1 ppb. Maximum concentrations of 2,6-TDI exceeded 64 ppb at the finishing end(1).
[(1) Rando RJ et al; Am Ind Hyg Assoc J 45: 199-203 (1984)]**PEER REVIEWED**

In a Finnish study, TDI vapor concentrations ranged from 25-80 ug/cu m for pouring, 14-44 ug/cu m for paper stripping, and 1-8 ug/cu m for cutting(1). Personal monitors measured 9-34 ug/cu m and 5-30 ug/cu m of the 2,4-isomer for pouring and paper stripping, respectively(1). While 2,4-**toluene** diisocyanate constitutes 80% of TDI, and 2,6-**toluene** diisocyanate 20%, the 2,4-isomer is more reactive so that the concentration of the 2,6-isomer is higher in workplace air(1). The percentage of 2,4-**toluene** diisocyanate to total **toluene** diisocyanate measured with the personal monitors ranged from 29 to 69%(1). TDI levels of 1.3-2.8 ppb were detected in air inside a Swedish factory manufacturing polyurethanes(2).
[(1) Rosenberg C, Savolainen H; J Chromatography 367: 385-92 (1986) (2) Audunsson G et al; Intern J Environ Anal Chem 20: 85-100 (1985)]**PEER REVIEWED**

Mean concn ranges of TDI reported in ambient workplace air were 0.7-710 ug/cu m in TDI production, ND - 1490 ug/cu m during polyurethane foam production, 70-140 mg/cu m during elastomer production, 13 - 1050 ug/cu m during polyurethane foam use, 10-710 ug/cu m during polyurethane spray paint use, and <1-740 ug/cu m during the production of polyurethane-coated wire(1). Mean concn in personal samples ranged from ND-540 ug/cu m during polyurethane foam production and 2-1220 ug/cu m during polyurethane spray foam use(1). Additionally, mean concn of TDI released from insulation in a ship's hold was reported to be 120-150 ug/cu m and that released from coated fabric in a workplace 2-10 ug/cu m(1). During the outdoor application of TDI foam to a 40 ft diameter storage tanks, the mean atmospheric TDI concentration downwind from the spray gun was 0.3 ppm at 8 ft, 0.02 ppm at 40 ft, and 0.002 ppm at 150 ft(2). TDI was not detected more than 8 ft upwind of the spray gun(2). Air samples taken within two ft of the foam surface immediately after spraying had ceased was found to be 0.03 ppm(2). Mean TDI concentrations near the pumping equipment during material transfer was 0.02

ppm(2).

Environmental Fate:

TERRESTRIAL FATE: Ten days after a spill of 13 tons of **toluene** diisocyanate (TDI) onto swampy, wet forest soil, TDI and toluenediamines were found in the soil(1,2). The TDI solidified and the area was covered with sand. The soil concn of TDI and toluenediamine combined declined from the parts per thousand to parts per million range between 10 days and 12 wk after the spill(2). No TDI was detected in a connecting brook 10 days after the spill(2). After 6 years only TDI-derived polyureas were found at the site(1). In a simulated spill, 5 kg of TDI in a container was covered with 50 kg of sand and 5 kg of water at ambient temperatures and samples taken from the top and bottom of the sand pile. After 24 hr, 5.5% of the TDI remained unreacted and after 8 days 3.5% remained(2). The reaction product was largely polyureas(2).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985) (2) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-7 (1984)]**PEER REVIEWED**

AQUATIC FATE: When low concns of TDI are released into model river or seaway systems, it is hydrolyzed within a day. In order to simulate a spill of TDI in stagnant water, 0.5 liters of TDI was poured into 20 liters of water of pH 5, 7, or 9 at 20 deg C. A hard compact crust formed at the water TDI interface(1). This crust thickened over a period of 30 days until no liquid TDI remained. The solid crust contained <0.5% of the original TDI after 35 days(1). Another experiment were performed to simulate a spill into running water by pouring 0.5 l of TDI into 20 l of slowly overflowing water. Barely detectable amounts of toluenediamine were present in the overflow samples. As in the stagant water simulation, a crust formed that contained <0.5% of the original TDI after 35 days(1).
[(1) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-17 (1984)]**PEER REVIEWED**

ATMOSPHERIC FATE: Removal of TDI from the atmosphere is due to reaction with photochemically produced hydroxyl radicals (half-life 3.3 hr) as well as through dry deposition. Earlier ideas that reaction with water vapor was of major importance have not been substantiated in recent experiments.(SRC)
PEER REVIEWED

Environmental Biodegradation:

Toluene diisocyanates are expected to be hydrolyzed much more rapidly than they are attacked by microorganisms. The resulting **toluene** diamines are subject to a wide variety of biochemical transformations.
[ITC/USEPA; Information Review #231 (Draft) Toluene Diisocyanates p. 19 (1981)]**PEER REVIEWED**

Environmental Abiotic Degradation:

Toluene diisocyanate reacts readily with compounds containing active hydrogens, such as water, acids, and alcohols(2). Contact with bases may cause uncontrollable polymerization with rapid evolution of heat(2). In concentrated solutions, hydrolysis of one of the isocyanate groups to the amine is followed by rapid reaction of the amine with an isocyanate group on another molecule leading to dimers, oligimers, and polymers(2). In one experiment the hydrolysis product yield was 20% diamine and 80% polyurea(3). When 50 ppm of **toluene** diisocyanate was added to model river and seawater systems, the concn fell to 0.1 ppm or less at the end of 1 day(1).
[(1) Duff PB; The Fate of TDI in the Environment. In: Polyurethane-New Paths to Progress Marketing Technology. Proc. of the SPI 6th Inter. Tech. Marketing Conf. pp. 408-12 (1983) (2) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985) (3) Sopach ED, Boltromeyuk LP; Gig Sanit 7: 10-3 (1974)]**PEER REVIEWED**

Gas phase loss of TDI was originally thought to be due to reaction of TDI with water vapor. One early work showed that the percent disappearance of TDI in air depended almost solely on the water vapor concentration, increasing 3.2% per unit increase in absolute humidity (g water/kg dry air), so that at 15 g water/kg dry air, a 50% reduction in TDI was obtained(2). These reductions were obtained after 8 sec and did not differ appreciably after 75 sec(2). More recent work contradicted these earlier findings and a program was instituted to study the gas-phase reactions between TDI and water using a room sized environmental chamber(1). They found that over a relative humidity range of 7-70%, the loss rate of TDI was independent of humidity and no toluenediamine or TDI-urea products could be detected(1). No

evidence of gas phase reaction between water and TDI could be detected. The loss of TDI was due to adsorption to the chamber walls(1).
[(1) Holdren MW et al; Am Ind Hyg Assoc J 45: 626-33 (1984) (2) Dyson WL, Hermann ER; Amer Ind Hyg Assoc J 32: 741-4 (1971)]**PEER REVIEWED**

Subsequent experiments were performed in the environmental chamber to assess the importance of photolysis, reaction with free radicals, and adsorption onto particulate matter as atmospheric removal processes(1). The loss rate of TDI in irradiated clean air was first order with a half-life of 3.3 hr(1). By using a free radical scavenger, it was shown that free-radicals and not photolysis was responsible for the removal. The half-life is consistant with the reaction with photochemically generated hydroxyl radicals(1). The addition of a urban surrogate hydrocarbon mixture (polluted urban air), did not significantly alter removal rates(1). The concentration of hydroxyl radicals generally increases in polluted air resulting in shorter half-lives which were not observed in the above study(SRC). Adsorption to particulate matter was not significant(1).
[(1) Duff PB; Proc of the SPI Tech/Mark Conf 29: 9-14 (1985)]**PEER REVIEWED**

Volatilization from Water/Soil:

The vapor pressure of TDI is 0.01 torr at 20 deg C(1), and therefore spilled TDI will not readily volatilize from soil surfaces or other surfaces(SRC). Since TDI reacts with water, volatilization from water should not be important(SRC).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985)]**PEER REVIEWED**

Environmental Water Concentrations:

Toluene diisocyanate has been reported in the waste-water of a furniture manufacturing area in a concn range of 0.1-4.1 mg/l.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

Effluent Concentrations:

TDI has been reported in waste water from furniture manufacturing in the concn range of 0.1-4.1 ppm(1). However the coloremetric method used did not distinguish between the disocyanate or the corresponding amine(1). In view of TDI's rapid reactivity with water, it is probable that the chemical detected was the corresponding amine(SRC). Stack exhaust from a polyurethane foam production plant were reported to contain 100-17,700 ug/cu m of TDI(1).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985)]**PEER REVIEWED**

Sediment/Soil Concentrations:

Ten days after an accident resulting in the spillage of 13 tons of **toluene** diisocyanate from a lorry on a swampy wet forest area, **toluene** diisocyanate and toluenediamine were /found/ in the soil. After six yr,

only **toluene** diisocyanate-derived polyureas were found in soil samples taken at the same site.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

Other Environmental Concentrations:

TDI monomer has been found in a urethane foam fabric coating in concn of <200 ppm(1).

Artificial Pollution Sources:

Levels of 100-17,700 ug/cu m **toluene** diisocyanate were reported in samples from the stack exhaust of a polyurethane foam production plant.
[IARC. Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man. Geneva: World Health Organization, International Agency for Research on Cancer,1972-PRESENT. (Multivolume work).,p. V39 299 (1986)]**PEER REVIEWED**

TDI may be released to the environment, primarily as stack and fugitive emissions into air during its commercial production, handling, and processing prior to polyurethane foam production(1). It may also be released during the manufacture of polyurethane foam products and coatings, from sprays, insulation materials, and polyurethane foam coated fabrics(1,3). About 0.005% of the TDI used in flexible foam slabstock plants is released in vent stack exhaust and this contains <50% of the 2,4-isomer(2). Large quantities of TDI are transported by rail, road, and sea and releases may occur from accidental spills on land or in surface waters during loading or transit(2).

Environmental Fate:

TERRESTRIAL FATE: Ten days after a spill of 13 tons of **toluene** diisocyanate (TDI) onto swampy, wet forest soil, TDI and toluenediamines were found in the soil(1,2). The TDI solidified and the area was covered with sand. The soil concn of TDI and toluenediamine combined declined from the parts per thousand to parts per million range between 10 days and 12 wk after the spill(2). No TDI was detected in a connecting brook 10 days after the spill(2). After 6 years only TDI-derived polyureas were found at the site(1). In a simulated spill, 5 kg of TDI in a container was covered with 50 kg of sand and 5 kg of water at ambient temperatures and samples taken from the top and bottom of the sand pile. After 24 hr, 5.5% of the TDI remained unreacted and after 8 days 3.5% remained(2). The reaction product was largely polyureas(2).
[(1) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985) (2) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-7 (1984)]**PEER REVIEWED**

AQUATIC FATE: When low concns of TDI are released into model river or seaway systems, it is hydrolyzed within a day. In order to simulate a spill of TDI in stagnant water, 0.5 liters of TDI was poured into 20 liters of water of pH 5, 7, or 9 at 20 deg C. A hard compact crust formed at the water TDI interface(1). This crust thickened over a period of 30 days until no liquid TDI remained. The solid crust contained <0.5% of the original TDI after 35 days(1). Another experiment were performed to simulate a spill into running water by pouring 0.5 l of TDI into 20 l of slowly overflowing water. Barely detectable amounts of toluenediamine were present in the overflow samples. As in the stagant water simulation, a crust formed that contained <0.5% of the original TDI after 35 days(1).
[(1) Brochhagen FK, Grieveson BM; Cellular Ploymers 3: 11-17 (1984)]**PEER REVIEWED**

ATMOSPHERIC FATE: Removal of TDI from the atmosphere is due to reaction with photochemically produced hydroxyl radicals (half-life 3.3 hr) as well as through dry deposition. Earlier ideas that reaction with water vapor was of major importance have not been substantiated in recent experiments.(SRC)

Environmental Abiotic Degradation:

Toluene diisocyanate reacts readily with compounds containing active hydrogens, such as water, acids, and alcohols(2). Contact with bases may cause uncontrollable polymerization with rapid evolution of heat(2). In concentrated solutions, hydrolysis of one of the isocyanate groups to the amine is followed by rapid reaction of the amine with an isocyanate group on another molecule leading to dimers, oligimers, and polymers(2). In one experiment the hydrolysis product yield was 20% diamine and 80% polyurea(3). When 50 ppm of **toluene** diisocyanate was added to model river and seawater systems, the concn fell to 0.1 ppm or less at the end of 1 day(1).

[(1) Duff PB; The Fate of TDI in the Environment. In: Polyurethane-New Paths to Progress Marketing Technology. Proc. of the SPI 6th Inter. Tech. Marketing Conf. pp. 408-12 (1983) (2) IARC Monograph on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. 39: 287-323 (1985) (3) Sopach ED, Boltromeyuk LP; Gig Sanit 7: 10-3 (1974)]**PEER REVIEWED**

Gas phase loss of TDI was originally thought to be due to reaction of TDI with water vapor. One early work showed that the percent disappearance of TDI in air depended almost solely on the water vapor concentration, increasing 3.2% per unit increase in absolute humidity (g water/kg dry air), so that at 15 g water/kg dry air, a 50% reduction in TDI was obtained(2). These reductions were obtained after 8 sec and did not differ appreciably after 75 sec(2). More recent work contradicted these earlier findings and a program was instituted to study the gas-phase reactions between TDI and water using a room sized environmental chamber(1). They found that over a relative humidity range of 7-70%, the loss rate of TDI was independent of humidity and no toluenediamine or TDI-urea products could be detected(1). No evidence of gas phase reaction between water and TDI could be detected. The loss of TDI was due to adsorption to the chamber walls(1).

[(1) Holdren MW et al; Am Ind Hyg Assoc J 45: 626-33 (1984) (2) Dyson WL, Hermann ER; Amer Ind Hyg Assoc J 32: 741-4 (1971)]**PEER REVIEWED**

Subsequent experiments were performed in the environmental chamber to assess the importance of photolysis, reaction with free radicals, and adsorption onto particulate matter as atmospheric removal processes(1). The loss rate of TDI in irradiated clean air was first order with a half-life of 3.3 hr(1). By using a free radical scavenger, it was shown that free-radicals and not photolysis was responsible for the removal. The half-life is consistant with the reaction with photochemically generated hydroxyl radicals(1). The addition of a urban surrogate hydrocarbon mixture (polluted urban air), did not significantly alter removal rates(1). The concentration of hydroxyl radicals generally increases in polluted air resulting in shorter half-lives which were not observed in the above study(SRC). Adsorption to particulate matter was not significant(1).

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Combustible material: may burn but does not ignite readily. Substance will react with water (some violently) releasing flammable, toxic or corrosive gases and runoff. When heated, vapors may form explosive mixtures with air: indoors, outdoors, and sewers explosion hazards. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapors may travel to source of ignition and flash back. Contact with metals may evolve flammable hydrogen gas. Containers may explode when heated or if contaminated with water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Health: TOXIC; inhalation, ingestion or contact (skin, eyes) with vapors, dusts or substance may cause severe injury, burns, or death. Reaction with water or moist air will release toxic, corrosive or flammable gases. Reaction with water may generate much heat which will increase the concentration of fumes in the air. Fire will produce irritating, corrosive and/or toxic gases. Runoff from fire control or dilution water may be corrosive and/or toxic and cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Evacuation: Spill: See the Table of Initial Isolation and Protective Action Distances for highlighted substances. For non-highlighted substances, increase, in the downwind direction, as necessary, the isolation distance shown under "PUBLIC SAFETY". Fire: If tank, rail car or tank truck is involved in a fire, ISOLATE for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.

[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Fire: Note: Most foams will react with the material and release corrosive/toxic gases. Small fires: CO2, dry chemical, dry sand, alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. FOR CHLOROSILANES, DO NOT USE WATER; use AFFF alcohol-resistant medium expansion foam. Move containers from fire area if you can do it without risk. Do not use straight streams. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Do not get water inside containers. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks.

[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Stop leak if you can do it without risk. A vapor suppressing foam may be used to reduce vapors. FOR CHLOROSILANES, use AFFF alcohol-resistant medium expansion foam to reduce vapors. DO NOT GET WATER on spilled substance or inside containers. Use water spray to reduce vapors or divert vapor cloud drift. Prevent entry into waterways, sewers, basements or confined areas. Small spills: Cover with DRY earth, DRY sand, or other non-combustible material followed with plastic sheet to minimize spreading or contact with rain. Use clean non-sparking tools to collect material and place it into loosely covered plastic containers for later disposal.

[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S.

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Do not use mouth-to-mouth method if victim ingested or inhaled the substance; induce artificial respiration with the aid of a pocket mask equipped with a one-way valve or other proper respiratory medical device. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. For minor skin contact, avoid spreading material on unaffected skin. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Disposal Methods:

Generators of waste (equal to or greater than 100 kg/mo) containing this contaminant, EPA hazardous waste number U223, must conform with USEPA regulations in storage, transportation, treatment and disposal of waste.
[40 CFR 240-280, 300-306, 702-799 (7/1/91)]**PEER REVIEWED**

Toluene diisocyanate is a waste chemical stream constituent which may be subjected to ultimate disposal by controlled incineration. Controlled incineration: Oxides of nitrogen are removed from the effluent gas by scrubbers and/or thermal devices.
[USEPA; Engineering Handbook for Hazardous Waste Incineration p.2-10 (1981) EPA 68-03-3025]**PEER REVIEWED**

A potential candidate for rotary kiln incineration at a temperature range of 820 to 1,600 deg C and residence times of seconds for liquids and gases, and hours for solids. A potential candidate for liquid injection incineration at a temperature range of 650 to 1600 deg C and a residence time of 0.1 to 2 seconds. A potential candidate for fluidized bed incineration at a temperature range of 450 to 980 deg C and residence times of seconds for liquids and gases, and longer for solids.
[USEPA; Engineering Handbook for Hazardous Waste Incineration p.3-16 (1981) EPA 68-03-3025]**PEER REVIEWED**

This compound should be susceptible to removal from waste water by air stripping.
[USEPA/ORD; Innovative and Alternative Technology Assessment Manual pp.3-5, 3-11,12 (1980) EPA 430/9-78-009]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": There is no universal method of disposal that has been proved satisfactory for all carcinogenic compounds & specific methods of chem destruction ... published have not been tested on all kinds of carcinogen-containing waste. ... Summary of avail methods & recommendations ... /given/ must be treated as guide only. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 14]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": ... Incineration may be only feasible method for disposal of contaminated laboratory waste from biological expt. However, not all incinerators are suitable for this purpose. The most efficient type ... is probably the gas-fired type, in which a first-stage combustion with a less than stoichiometric air:fuel ratio is followed by a second stage with excess air. Some ... are designed to accept ... aqueous & organic-solvent solutions, otherwise it is necessary ... to absorb soln onto suitable combustible material, such as sawdust. Alternatively, chem destruction may be used, esp when small quantities ... are to be destroyed in laboratory. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 15]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": HEPA (high-efficiency particulate arrestor) filters ... can be disposed of by incineration. For spent charcoal filters, the adsorbed material can be stripped off at high temp & carcinogenic wastes generated by this treatment conducted to & burned in an incinerator. ... LIQUID WASTE: ... Disposal should be carried out by incineration at temp that ... ensure complete combustion. SOLID WASTE: Carcasses of lab animals, cage litter & misc solid wastes ... should be disposed of by incineration at temp high enough to ensure destruction of chem carcinogens or their

metabolites. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 15]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": ... Small quantities of ... some carcinogens can be destroyed using chem reactions ... but no general rules can be given. ... As a general technique ... treatment with sodium dichromate in strong sulfuric acid can be used. The time necessary for destruction ... is seldom known ... but 1-2 days is generally considered sufficient when freshly prepd reagent is used. ... Carcinogens that are easily oxidizable can be destroyed with milder oxidative agents, such as sat soln of potassium permanganate in acetone, which appears to be a suitable agent for destruction of hydrazines or of compounds containing isolated carbon-carbon double bonds. Concn or 50% aqueous sodium hypochlorite can also be used as an oxidizing agent. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 16]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Carcinogens that are alkylating, arylating or acylating agents per se can be destroyed by reaction with appropriate nucleophiles, such as water, hydroxyl ions, ammonia, thiols & thiosulfate. The reactivity of various alkylating agents varies greatly ... & is also influenced by sol of agent in the reaction medium. To facilitate the complete reaction, it is suggested that the agents be dissolved in ethanol or similar solvents. ... No method should be applied ... until it has been thoroughly tested for its effectiveness & safety on material to be inactivated. For example, in case of destruction of alkylating agents, it is possible to detect residual compounds by reaction with 4(4-nitrobenzyl)-pyridine. /Chemical Carcinogens/

DOT Emergency Guidelines:

Fire or explosion: Combustible material: may burn but does not ignite readily. Substance will react with water (some violently) releasing flammable, toxic or corrosive gases and runoff. When heated, vapors may form explosive mixtures with air: indoors, outdoors, and sewers explosion hazards. Most vapors are heavier than air. They will spread along ground and collect in low or confined areas (sewers, basements, tanks). Vapors may travel to source of ignition and flash back. Contact with metals may evolve flammable hydrogen gas. Containers may explode when heated or if contaminated with water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Health: TOXIC; inhalation, ingestion or contact (skin, eyes) with vapors, dusts or substance may cause severe injury, burns, or death. Reaction with water or moist air will release toxic, corrosive or flammable gases. Reaction with water may generate much heat which will increase the concentration of fumes in the air. Fire will produce irritating, corrosive and/or toxic gases. Runoff from fire control or dilution water may be corrosive and/or toxic and cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Public safety: CALL Emergency Response Telephone Number on Shipping Paper first. If Shipping Paper not available or no answer, refer to appropriate telephone number listed on the inside back cover. Isolate spill or leak area immediately for at least 50 to 100 meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate enclosed areas.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-156]**QC REVIEWED**

Fire: Note: Most foams will react with the material and release corrosive/toxic gases. Small fires: CO2, dry chemical, dry sand, alcohol-resistant foam. Large fires: Water spray, fog or alcohol-resistant foam. FOR CHLOROSILANES, DO NOT USE WATER; use AFFF alcohol-resistant medium expansion foam. Move containers from fire area if you can do it without risk. Do not use straight streams. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Do not get water inside containers. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. ALWAYS stay away from the ends of tanks.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-156]**QC REVIEWED**

Spill or leak: ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Stop leak if you can do it without risk. A vapor suppressing foam may be used to reduce vapors. FOR CHLOROSILANES, use AFFF alcohol-resistant medium expansion foam to reduce vapors. DO NOT GET WATER on spilled substance or inside containers. Use water spray to reduce vapors or divert vapor cloud drift. Prevent entry into waterways, sewers, basements or confined areas. Small spills: Cover with DRY earth, DRY sand, or other non-combustible material followed with plastic sheet to minimize spreading or contact with rain. Use clean non-sparking tools to collect material and place it into loosely covered plastic containers for later disposal.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. PRECAUTIONS FOR "CARCINOGENS": Principles that apply to chem or biochem lab also apply to microbiological & cell-culture labs ... Special consideration should be given to route of admin. ... Safest method of administering volatile carcinogen is by injection of a soln. Admin by topical application, gavage, or intratracheal instillation should be performed under hood. If chem will be exhaled, animals should be kept under hood during this period. Inhalation exposure requires special equipment. ... unless specifically required, routes of admin other than in the diet should be used. Mixing of carcinogen in diet should be carried out in sealed mixers under fume hood, from which the exhaust is fitted with an efficient particulate filter. Techniques for cleaning mixer & hood should be devised before expt begun. When mixing diets, special protective clothing &, possibly, respirators may be required. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 9]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": When ... admin in diet or applied to skin, animals should be kept in cages with solid bottoms & sides & fitted with a filter top. When volatile carcinogens are given, filter tops should not be used. Cages which have been used to house animals that received carcinogens should be decontaminated. Cage-cleaning facilities should be installed in area in which carcinogens are being used, to avoid moving of ... contaminated /cages/. It is difficult to ensure that cages are decontaminated, & monitoring methods are necessary. Situations may exist in which the use of disposable cages should be recommended, depending on type & amt of carcinogen & efficiency with which it can be removed. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 10]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": To eliminate risk that ... contamination in lab could build up during conduct of expt, periodic checks should be carried out on lab atmospheres, surfaces, such as walls, floors & benches, & ... interior of fume hoods & airducts. As well as regular monitoring, check must be carried out after cleaning-up of spillage. Sensitive methods are required when testing lab atmospheres. ... Methods ... should ... where possible, be simple & sensitive. ... /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for

Research on Cancer, 1979. 10]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Rooms in which obvious contamination has occurred, such as spillage, should be decontaminated by lab personnel engaged in expt. Design of expt should ... avoid contamination of permanent equipment. ... Procedures should ensure that maintenance workers are not exposed to carcinogens. ... Particular care should be taken to avoid contamination of drains or ventilation ducts. In cleaning labs, procedures should be used which do not produce aerosols or dispersal of dust, ie, wet mop or vacuum cleaner equipped with high-efficiency particulate filter on exhaust, which are avail commercially, should be used. Sweeping, brushing & use of dry dusters or mops should be prohibited. Grossly contaminated cleaning materials should not be re-used ... If gowns or towels are contaminated, they should not be sent to laundry, but ... decontaminated or burnt, to avoid any hazard to laundry personnel. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 10]**PEER REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Doors leading into areas where carcinogens are used ... should be marked distinctively with appropriate labels. Access ... limited to persons involved in expt. ... A prominently displayed notice should give the name of the Scientific Investigator or other person who can advise in an emergency & who can inform others (such as firemen) on the handling of carcinogenic substances. /Chemical Carcinogens/
[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 11]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.

Shipment Methods and Regulations:

No person may /transport,/ offer or accept a hazardous material for transportation in commerce unless that person is registered in conformance ... and the hazardous material is properly classed, described, packaged, marked, labeled, and in condition for shipment as required or authorized by ... /the hazardous materials regulations (49 CFR 171-177)./

[49 CFR 171.2 (7/1/96)]**QC REVIEWED**

The International Air Transport Association (IATA) Dangerous Goods Regulations are published by the IATA Dangerous Goods Board pursuant to IATA Resolutions 618 and 619 and constitute a manual of industry carrier regulations to be followed by all IATA Member airlines when transporting hazardous materials.

[IATA. Dangerous Goods Regulations. 38th ed. Montreal, Canada and Geneva, Switzerland: International Air Transport Association, Dangerous Goods Board, January, 1997. 221]**QC REVIEWED**

The International Maritime Dangerous Goods Code lays down basic principles for transporting hazardous chemicals. Detailed recommendations for individual substances and a number of recommendations for good practice are included in the classes dealing with such substances. A general index of technical names has also been compiled. This index should always be consulted when attempting to locate the appropriate procedures to be used when shipping any substance or article.

[IMDG; International Maritime Dangerous Goods Code; International Maritime Organization p.6239 (1988)]**QC REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": Procurement ... of unduly large amt ... should be avoided. To avoid spilling, carcinogens should be transported in securely sealed glass bottles or ampoules, which should themselves be placed inside strong screw-cap or snap-top container that will not open when dropped & will resist attack from the carcinogen. Both bottle & the outside container should be appropriately labelled. ... National post offices, railway companies, road haulage companies & airlines have regulations governing transport of hazardous materials. These authorities should be consulted before ... material is shipped. /Chemical Carcinogens/

[Montesano, R., H. Bartsch, E.Boyland, G. Della Porta, L. Fishbein, R. A. Griesemer, A.B. Swan, L. Tomatis, and W. Davis (eds.). Handling Chemical Carcinogens in the Laboratory:Problems of Safety. IARC Scientific Publications No. 33. Lyon, France: International Agency for Research on Cancer, 1979. 13]**QC REVIEWED**

PRECAUTIONS FOR "CARCINOGENS": When no regulations exist, the following procedure must be adopted. The carcinogen should be enclosed in a securely sealed, watertight container (primary container), which should be enclosed in a second, unbreakable, leakproof container that will withstand chem attack from the carcinogen (secondary container). The space between primary & secondary container should be filled with absorbent material, which would withstand chem attack from the carcinogen & is sufficient to absorb the entire contents of the primary container in the event of breakage or leakage. Each secondary container should then be enclosed in a strong outer box. The space between

the secondary container & the outer box should be filled with an appropriate quantity of shock-absorbent material. Sender should use fastest & most secure form of transport & notify recipient of its departure. If parcel is not received when expected, carrier should be informed so that immediate effort can be made to find it. Traffic schedules should be consulted to avoid ... arrival on weekend or holiday ... /Chemical Carcinogens/

Isocyanate determination air paper tape Hydrazine determination air paper tape;Air analysis Hydrazine deriv. and **toluene** diisocyanate determination. in, miniature paper tape apparatus for [Hughes WT Jr; Anal Instrum (Research Triangle Park, N. C.) 22: 87-98 (1986)]**PEER REVIEWED**

A passive monitor for **toluene** diisocyanate which utilizes microporous Teflon diffusion membranes and a 0.5% sulfuric acid absorbing medium was evaluated. The collection rate of **toluene** diisocyanate is proportional to exposure dose from 10 to at least 300 ppb.hr, and response is equivalent for 2,4- and 2,6-**toluene** diisocyanate. Collection rate is independent of humidity and normal atmospheric pressure variations, while temperature causes a decrease of 1.0% per deg C. Negative interference caused by ambient nitrogen dioxide is eliminated by addition of sulfamic acid to the collecting medium. N-Ethylmorpholine is a positive interferent. Field testing of the sampler against a reference impinger technique indicated a positive bias when **toluene** diisocyanate is aerosolized. [Rando RJ et al; Am Ind Hyg Assoc J 50 (1): 8-14 (1989)]**PEER REVIEWED**

A solvent free sampling method for airborne **toluene** diisocyanate was described. Air samples were collected on quartz fiber filters impregnated with 1-(2-methoxyphenyl)piperazine. **Toluene** diisocyanate in the samples reacted with 1-(2-methoxyphenyl)piperazine to form urea derivatives which after dissolution in methanol were analyzed by reversed or normal phase HPLC. When reversed phase HPLC was used, a C18 bonded phase column was utilized. A cyano amino bonded phase column was used with normal phase HPLC. An ultraviolet detector set at a wavelength 250 nanometers was also used. Detection limits for a 15 liter air sample based on a 5 mm peak height were 0.02 to 0.04 mg/cu m, corresponding to 0.5 to 1 nanograms of **toluene** diisocyanate injected. The method was used to sample laboratory generated **toluene** diisocyanate containing atmospheres over the relative humidity range 11 to 75% and temperature range 20 to 50 deg C. In the study of the effects of humidity, samples were also collected with gas bubblers and silica gel tubes for comparison purposes. **toluene** diisocyanate concn in the collected samples increased linearly with incr temperature. When the samples were collected on the 1-(2-methoxyphenyl)piperazine coated fibers the collected **toluene** diisocyanate concn were not affected by changes in relative humidity. Collection efficiency of the bubblers and silica gel tubes decr for humidities in excess of 45%. It was concluded that the 1-(2-methoxyphenyl)piperazine impregnated quartz fiber filter method for **toluene** diisocyanate sampling is convenient and efficient, and that collection efficiency does not appear to be affected by humidity. [Robert A, Simon P; Chromatographia 23 (7):507-11 (1987)]**PEER REVIEWED**

Isocyanate determination air paper tape Hydrazine determination air paper tape;Air analysis Hydrazine deriv. and **toluene** diisocyanate determination. in, miniature paper tape apparatus for [Hughes WT Jr; Anal Instrum (Research Triangle Park, N. C.) 22: 87-98 (1986)]**PEER REVIEWED**

A passive monitor for **toluene** diisocyanate which utilizes microporous Teflon diffusion membranes and a 0.5% sulfuric acid absorbing medium was evaluated. The collection rate of **toluene** diisocyanate is proportional to exposure dose from 10 to at least 300 ppb.hr, and response is equivalent for 2,4- and 2,6-**toluene** diisocyanate. Collection rate is independent of humidity and normal atmospheric pressure variations, while temperature causes a decrease of 1.0% per deg C. Negative interference caused by ambient nitrogen dioxide is eliminated by addition of sulfamic acid to the collecting medium. N-Ethylmorpholine is a positive interferent. Field testing of the sampler against a reference impinger technique indicated a positive bias when **toluene** diisocyanate is aerosolized. [Rando RJ et al; Am Ind Hyg Assoc J 50 (1): 8-14 (1989)]**PEER REVIEWED**

A solvent free sampling method for airborne **toluene** diisocyanate was described. Air samples were collected on quartz fiber filters impregnated with 1-(2-methoxyphenyl)piperazine. **Toluene** diisocyanate in the samples reacted with 1-(2-methoxyphenyl)piperazine to form urea derivatives which after dissolution in methanol were analyzed by reversed or normal phase HPLC. When reversed phase HPLC was used, a C18 bonded phase column was utilized. A cyano amino bonded phase column was used with normal phase HPLC. An ultraviolet detector set at a wavelength 250 nanometers was also used. Detection limits for a 15 liter air sample based on a 5 mm peak height were 0.02 to 0.04 mg/cu m, corresponding to 0.5 to 1 nanograms of **toluene** diisocyanate injected. The method was used to sample laboratory generated **toluene** diisocyanate containing atmospheres over the relative humidity range 11 to 75% and temperature range 20 to 50 deg C. In the study of the effects of humidity, samples were also collected with gas bubblers and silica gel tubes for comparison purposes. **toluene** diisocyanate concn in the collected samples increased linearly with incr temperature. When the samples were collected on the 1-(2-methoxyphenyl)piperazine coated fibers the collected **toluene** diisocyanate concn were not affected by changes in relative humidity. Collection efficiency of the bubblers and silica gel tubes decr for humidities in excess of 45%. It was concluded that the 1-(2-methoxyphenyl)piperazine impregnated quartz fiber filter method for **toluene** diisocyanate sampling is convenient and efficient, and that collection efficiency does not appear to be affected by humidity. [Robert A, Simon P; Chromatographia 23 (7):507-11 (1987)]**PEER REVIEWED**

EPA Method 8020. For the analysis of solid waste, a representative sample (solid or liquid) is collected in a standard 40 ml glass screw cap VOA vial equipped with a Teflon faced silicone septum. Sample agitation, as well as contamination of the sample with air, must be avoided. Two vials are filled per sample location, then placed in separate plastic bags for shipment and storage. /**Toluene**/
