Fire and Explosion Hazard Data

==========
Flash Point: 18F
Flash Point Method: TCC
Lower Explosive Limit: 1.7%
Upper Explosive Limit: N/K
Extinguishing Media: NFPA CLASS B EXTINGUISHERS (CO2/FOAM) FOR CLASS 1B LIQUID FIRES.
Special Fire Fighting Proc: WATER SPRAY MAY BE INEFFECTIVE. DON'T ENTER CONFINED FIRE-SPACE W/O FULL BUNKER GEAR. USE FOG NOZZLES IF WATER IS USED. NIOSH APPROVED POSITIVE-PRESSURE SCBA.

Unusual Fire And Expl Hazrds: CLOSED CONTAINERS MAY EXPLODE IF EXPOSED TO EXTREME HEAT/HOT SURFACES/SPARKS/OPEN FLAME. VAPORS MAY IGNITE EXPLOSIVELY/ SPREAD LONG DISTANCES.

Reactivity Data

Stability: YES
Cond To Avoid (Stability): ISOLATE FROM OXIDIZERS, HEAT, SPARKS, OPEN FLAME, & HOT SURFACES.
Materials To Avoid: ISOLATE FORM STRONG OXIDIZERS SUCH AS PERMANGANATE, CHROMATE & PEROXIDES.
Hazardous Decomp Products: CO, CO2
Hazardous Poly Occur: NO
Conditions To Avoid (Poly): N/K

Health Hazard Data

LD50-LC50 Mixture: ORAL LD50 (RATS) 3000 MG/KG
Route Of Entry - Inhalation: YES
Route Of Entry - Skin: YES
Route Of Entry - Ingestion: YES
Health Haz Acute And Chronic: SKIN: IRRITATION, DEFATTING, DERMATITIS, REDNESS. EYES: TEARING, BLURRED VISION. INGESTION: HARMFUL/FATAL. ABDOMINAL IRRITATION, NAUSEA, VOMITING & DIARRHEA. INHALATION: IRRITATION.
Carcinogenicity - NTP: NO
Carcinogenicity - IARC: NO
Carcinogenicity - OSHA: NO
Explanation Carcinogenicity: NONE
Signs/Symptoms Of Overexp: INHALATION: IRRITATION. EYE/SKIN: IRRITATION. INESTION: HARMFUL/FATAL. STUDIES WITH LABORATORY ANIMALS INDICATES. THIS PRODUCT CAN CAUSE DAMAGE TO FETUS.
Med Cond Aggravated By Exp: PERSONS W/SEVERE SKIN, LIVER OR KIDNEY PROBLEMS SHOULD AVOID USE.
Emergency/First Aid Proc: SKIN: FLUSH W/PLENTY OF WATER. EYES: FLUSH W/PLENTY OF WATER FOR 15 MINUTES & GET MEDICAL ATTENTION. INHALATION: REMOVE TO FRESH AIR. IF BREATHING IS DIFFICULT GIVE OXYGEN. IF BREATHING HAS STOPPED GIVE ARTIFICIAL RESPIRATION. INGESTION: CALL PHYSICIAN

Report for NIIN: 00F009088

IMMEDIATELY. NEVER GIVE ANYTHING BY MOUTH TO AN UNCONSCIOUS PERSON.

Precautions for Safe Handling and Use

Steps If Matl Released/Spill: MOP UP W/ABSORBENT MATERIAL & TRANSFER TO HOOD. STOP SPILL AT SOURCE. DIKE AREA & CONTAIN. PUMP LIQUID TO SALVAGE TANK. REMAINDER MAY BE TAKEN UP ON ABSORBENT MATERIAL & SHOVELED INTO CONTAINERS.
Neutralizing Agent: N/R
Waste Disposal Method: DISPOSE OF REMAINDER BY LEGALLY APPLICABLE METHODS. RECYCLE/INCINERATE OBSERVING LOCAL, STATE & FEDERAL HEALTH SAFETY & POLLUTION LAWS.
Precautions-Handling/Storing: DON'T STORE >120F. AVOID FREE FALL OF LIQUID. GROUND CONTAINER FOR TRANSFERRING. WASH THOROUGHLY AFTER HANDLING. FOR INDUSTRY USE ONLY.
Other Precautions: KEEP OUT OF THE REACH OF CHILDREN. AVOID BREATHING VAPOR/SPRAY MIST/CONTACT W/SKIN & EYES. KEEP CONTAINER TIGHTLY CLOSED & UPRIGHT WHEN NOT IN USE TO PREVENT LEAKAGE. DON'T FLAME CUT, SAW, DRILL, BRAZE/WELD.

Control Measures

Respiratory Protection: VENTILATE TO KEEP AIR <90 PPM. USE A NIOSH APPROVED POSITIVE-PRESSURE SELF-CONTAINED BREATHING APPARATUS FOR EMERGENCIES.
Ventilation: MECHANICAL: ACCEPTABLE.
Protective Gloves: IMPERVIOUS
Eye Protection: GOGGLES, FACE SHIELD
Other Protective Equipment: APRON & FOOTWEAR IMPERVIOUS TO THIS MATERIAL. WASH CLOTHING BEFORE REUSE.
Work Hygienic Practices: WASH CLOTHING BEFORE REUSE. WASH THOROUGHLY AFTER HANDLING.
Suppl. Safety & Health Data: N/K

ETHYL ACETATE (141-78-6)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards**

		Reference(s)
Recognized:	--	
Suspected:	Neurotoxicant	DAN RTECS
	Respiratory Toxicant	RTECS
	Skin or Sense Organ Toxicant	RTECS

- **Hazard Rankings**

  More hazardous than most chemicals in 3 out of 5 ranking systems.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.
  Used in at least 6 industries.
  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.

- **Profile of Environmental Release and Waste Generation**

  No data on environmental releases in Scorecard.

- **Regulatory Coverage**

  On at least 2 federal regulatory lists.

- **Basic Testing to Identify Chemical Hazards**

  2 of 8 basic tests to identify chemical hazards have not been conducted on this chemical, or are not publicly available.

- **Information Needed for Safety Assessment**

  Lacks at least some of the national data required for safety assessment.
  Scorecard has risk assessment data for this chemical.

- **Links**

About the Chemicals

section of Scorecard

Chemical Profile Search

Scorecard provides detailed information on more than 6,800 chemicals, including all the chemicals used in large amounts in the United States and all the chemicals regulated under major environmental laws. You can search for information by typing in the chemical's name (or any common synonym) or the chemical's standard identification number (Chemical Abstracts Service or CAS registry number).

Name (or portion of name):

CAS number :

Rank Chemicals by Reported TRI Releases

For the 650 chemicals covered by the Toxics Release Inventory, Scorecard also lets you identify which are released or managed in the greatest quantity in your area. Scorecard tracks TRI chemicals using forty different ranking criteria, allowing you to select for chemicals in a specific TRI category (e.g, air releases), health effects category (e.g., air releases of recognized carcinogens), or risk-weighted category (e.g., ozone depleting potential).

Scorecard News...

Pact with oil refiners will result in cleaner air in several states

A recent agreement reached with three petroleum refiners will reduce polluted air emissions from nine petroleum refineries in Delaware, Louisiana, Texas, California and Washington. Motiva Enterprises, Equilon Enterprises and Deer Park Refining arrived at a settlement with the Justice Department, the EPA and others to cut air pollutants by more than 60,000 tons per year.

The agreement addresses nitrogen oxides, sulfur dioxide and particulate emissions, which cause serious respiratory problems and exacerbate cases of childhood asthma. Toxic air pollutants produced in the refining process can cause cancer.

Setting Priorities

Want to know what the most important environmental problems in your community are? Scorecard lists the top ranking issues in your area, based on comparative risk projects.

Pollution Locator

Find out about the pollution problems in your community. Search by geographic area or company name, or explore our maps. Reports are currently available on water quality, criteria and hazardous air pollutants, toxic chemical releases from manufacturing plants, Superfund sites and other sources of land contamination, hazards from lead pollution, and animal waste produced by factory farms.

Pollution Rankings

Scorecard highlights pollution problems that put an area into the worst 20% of areas in the country, or in its own state, and spotlights the companies responsible.

About the Chemicals

Find out whether a chemical has been tested for health effects and how harmful it may be for you and the environment.

Health Effects

Select a health problem that concerns you and find out what chemicals are recognized or suspected causes.

Find Your Community

Just enter your zip code and find out what pollutants are being released into your community --and who is responsible.

Find out about the regulatory programs that govern chemicals.

Discussion Forums

Share your views about pollution problems in your community, agricultural pollution, chemicals in consumer products, or the health effects of chemicals.

Take Action

Get the real story on toxics in your community and organize a community meeting on toxics using Scorecard's Guide. Scorecard lets you send faxes--for free--straight to the top-ranked polluters in your area or send email to key state and federal decision makers. We provide a directory of environmental organizations in your area and link you directly to volunteer opportunities with groups working on your issues. Or you can support Scorecard by running banners, distributing our data or maps, or contributing to Environmental Defense.

About the Chemicals: Data Descriptions

in the About the Chemicals section of Scorecard

Human Health Hazards

Exposure to toxic chemicals can cause any of several negative effects on human health, such as cancer or birth defects. Scorecard highlights the specific health hazards that each particular chemical poses. Twelve separate categories of health effects are covered. Some chemicals are widely recognized to be hazardous, while others are only suspected, so Scorecard always distinguishes between "recognized" and "suspected" health threats.

Hazard Rankings

Toxic chemicals can pose threats in many ways. How bad a particular chemical is depends on whether you are most concerned about its effects on humans, or its persistence in the environment, its damaging effects on ecosystems, or another factor. Scorecard shows how a chemical stacks up comparatively under different ranking systems. It then spotlights the chemicals that are most dangerous to human health and to the environment.

Chemical Use Profile

Why is industry using a toxic chemical in the first place? Scorecard uses official U.S. EPA information to tell you what each chemical is used for in various industries. If a chemical contributes to indoor air pollution, Scorecard points out the types of consumer products it may be found in. It also tells you if a chemical is one of the most widespread chemicals in commercial use (that is, an industrial chemical with annual U.S. production of more than one million pounds).

Profile of Releases and Waste Generation by Industrial Sector

What types of industries are responsible for releasing a particular chemical to the environment or for generating the greatest amount of chemical waste? Based on company reports to the EPA Toxics Release Inventory, Scorecard shows you the manufacturing sectors that release the largest quantities of a particular chemical or that generate the largest quantities as production-related waste.

Regulatory Coverage

Is government doing anything to control a toxic chemical? Scorecard tells you if a chemical is covered by federal environmental laws, or by California state laws (because California has unusually effective and innovative laws such as Proposition 65). It also tells you what chemicals are major environmental hazards because they damage the ozone layer, contribute to global warming, or persist in the environment.

Basic Testing to Identify Chemical Hazards

If an industrial chemical is allowed by law to be released into the environment, most people assume that it must have been tested and evaluated for its potential risks. Unfortunately, this is simply not true. Keeping chemical hazards under control requires information about what kinds of hazards each chemical poses. If the basic tests to check on a chemical's toxicity haven't been conducted, or if the results aren't publicly available, current laws tend to treat that chemical as if it were perfectly safe. For the chemicals being used in large quantities, Scorecard tells you whether or not eight basic types of tests for health and ecological effects have actually been conducted, based on the public record.

Information Needed for Safety Assessment

Could government assess a chemical's safety or risk? For most of the important industrial chemicals in U.S. commerce, government lacks the information to draw any scientifically based conclusion about the degree of risk--or lack of risk--that a chemical may pose when used. For every chemical in the database, Scorecard tells you whether or not the information needed to assess chemical risk is available. If it isn't, no one can accurately claim the chemical is "safe."

The key information for assessing a chemical's risk. To be able to assess the risk or safety of a chemical being released into the environment, two different kinds of information are needed: how toxic the chemical is, and how much people are actually being exposed to the chemical. For each chemical, Scorecard tells you whether or not there are risk assessment values (measuring its toxicity) available from the U.S. EPA or other authoritative scientific and regulatory agencies, and if so, what the values are. Scorecard also tells you whether information about human exposure to the chemical is being collected by national monitoring programs. Scorecard also directs you to sources of information about chemical contamination in your area.

Links

To make it easier to get more information on the hazards posed by a particular chemical, Scorecard points you to other web sites that provide publicly accessible fact sheets and other detailed technical information on chemicals. If there is a major toxicological profile of a chemical available online, it is rarely more than a click away.

Chemical Classes Scorecard tracks the classes that chemicals belong to and tells you which chemicals are members of which class. If you can't find something about one specific chemical, Scorecard can lead you to related chemicals for which more information may be available.

Other Web Sites Scorecard provides links to other database-backed web sites for further online research into chemical hazards.

Neurotoxicity Definition

from the Health Effects section of Scorecard

Neurotoxicity is defined as adverse effects on the structure or functioning of the central and/or peripheral nervous system that result from exposure to chemical substances. Neurotoxicants can cause morphological changes that lead to generalized damage to nerve cells (neuronopathy), injury to axons (axonopathy), or destruction of the myelin sheath (myelinopathy). It is well established that exposure to certain agricultural and industrial chemicals can damage the nervous system, resulting in neurological and behavioral dysfunction. Symptoms of neurotoxicity include muscle weakness, loss of sensation and motor control, tremors, alterations in cognition, and impaired functioning of the autonomic nervous system

The central nervous system (CNS) is composed of the brain and spinal cord. It is responsible for the higher functions of the nervous system (conditioned reflexes, learning, memory, judgment, and other functions of the mind). Chemicals toxic to the CNS can induce confusion, fatigue, irritability, and other behavioral changes. Methyl mercury and lead are known CNS toxicants. Exposure to these metals can also cause degenerative diseases of the brain (encephalopathy).

The peripheral nervous system (PNS) includes all the nerves not in the brain or spinal cord. These nerves carry sensory information and motor impulses. Damage to the nerve fibers of the PNS can disrupt communication between the CNS and the rest of the body. The organic solvents carbon disulfide, n-hexane,and trichloroethylene can harm the PNS, resulting in weakness in the lower limbs, prickling or tingling in the limbs (paresthesia), and loss of coordination.

Exposure to chemical agents can trigger a wide range of adverse effects on the nervous system. Neurotoxic substances can alter the propagation of nerve impulses or the activity of neurotransmitters and can disrupt the maintenance of the myelin sheath or the synthesis of protein. As a result, neurotoxicological assessments require the administration of a battery of functional and observational tests. Neurotoxicity in humans is most commonly measured by neurological tests that assess cognitive, sensory, and motor function.

Respiratory Toxicity Definition

from the Health Effects section of Scorecard

Respiratory toxicity is defined as adverse effects on the structure or functioning of the respiratory system that result from exposure to chemical substances. The respiratory tract consists of the nasal passages, pharynx, trachea, bronchi, and lungs. The chief function of the respiratory system is to ensure the efficient and effective exchange of oxygen and carbon dioxide between the blood and the air. Respiratory toxicants can produce a variety of acute and chronic pulmonary conditions, including local irritation, bronchitis, pulmonary edema, emphysema, and cancer.

It is well known that exposure to environmental and industrial chemicals can impair respiratory function. The air we breathe may contain toxic gases, vapors from solvents, aerosols, or particulate matter, all of which can cause respiratory harm. For example, scientific evidence has shown that ozone and fine particles pose a significant threat to respiratory health. Ground-level ozone, the main component in smog, causes breathing problems, aggravates asthma, and increases the severity and incidence of respiratory infections. More rarely, toxicants such as the herbicide paraquat may affect the respiratory tract after ingestion or dermal exposure.

Acute exposure to respiratory toxicants can trigger effects ranging from mild irritation to death by asphyxiation. Prolonged exposure to respiratory toxicants can cause structural damage to the lungs, resulting in chronic diseases such as pulmonary fibrosis, emphysema, and cancer. Pulmonary fibrosis is a serious lung disease in which airways become restricted or inflamed, leading to loss of elasticity and difficulty in breathing. It can be caused by exposure to coal dust, aluminum, beryllium, and carbides of tungsten. Emphysema, a degenerative and potentially fatal disease, is characterized by the inability of the lungs to fully expand and contract. The most common cause of emphysema is heavy cigarette smoking, but the disease can also be induced by exposure to aluminum, cadmium oxide, ozone, and nitrogen oxides. In addition, several toxicants are known to cause respiratory cancer. Examples of well-established human lung carcinogens are cigarette smoke, asbestos, arsenic, and nickel.

Skin or Sense Organ Toxicity Definition

from the Health Effects section of Scorecard

Skin and sense organ toxicity is defined as adverse effects on the skin or sense organs that result from exposure to chemical substances. The senses of smell, vision, hearing, and taste are referred to as the special senses. Sense organs may be injured by a variety of physical, chemical, and biological agents. The sense of smell can become impaired, for example, as a result of occupational exposure to the metals cadmium and nickel. A variety of chemicals that act both locally and systemically in the body can affect vision. Airborne chemicals such as inorganic irritant gases and vapors (ammonia, chlorine, hydrogen sulfide, and sulfur dioxide) formaldehyde, and many organic solvents can cause external eye irritation, including conjunctivitis and keratitis, in some cases reducing visual acuity. Chemical substances can induce auditory dysfunction as well. Occupational exposure to lead, for example, is associated with hearing loss.

The skin provides the body with a protective barrier, contains the nerves that support the sense of touch, and participates in the exchange of gases and liquids. When the skin is exposed to irritant compounds, symptoms of skin injury may occur: redness, inflammation, burning, and itching. Acute and chronic skin diseases that may result from contact with toxic agents include dermatitis, photosensitization, chloracne, urticaria, and cancer.

One of the most common chemically induced skin disorders is contact dermatitis, an inflammatory reaction of the skin that is usually restricted to the exposed areas. Clinical signs may include reddening, edema, itching, or a burning sensation. Strongly alkaline and acidic substances such as sodium hydroxide, sulfuric acid, and hydrofluoric acid are some of the irritants that can cause contact dermatitis and related disorders. A number of skin toxicants produce photosensitization, an abnormal reaction to ultraviolet and/or visible radiation. Known photosensitizers include anthraquinone dyes, sulfanilamide, and coal tar derivatives (anthracene, pyridine, acridine, and phenanthrene). Chloracne is a severe and unusual form of acne that can be triggered by exposure to certain halogenated aromatic compounds, such as polychlorinated dibenzo furans and dioxins. Finally, arsenic, coal tars, creosote oils, and ultraviolet light have been shown to induce skin cancer in humans.

High Production Volume (HPV) Chemicals

from Scorecard

DESCRIPTION

High production volume chemicals have annual production and/or importation volumes above 1 million pounds. In the U.S., 2,979 chemicals (excluding polymers) out of approximately 70,000 chemicals in commerce are used in such substantial quantities. While there are no authoritative estimates of the amount of total chemical use in the U.S., 4.4 to 7.1 trillion pounds of HPV chemicals are produced/imported annually.

The Organization for Economic Co-operation and Development (OECD) also maintains a list of 4,102 HPV chemicals. The OECD list includes chemicals which have annual production volumes greater than 1 thousand metric tonnes (2.2 million pounds) in more than one economically developed country.

REFERENCES

The U.S. list of HPV chemicals was generated from company reports of chemical use in 1990, submitted in response to the Toxic Substances Control Act Inventory Update Rule. Companies are only required to report their chemical production/imports as a range. The EPA is currently working on updating their HPV list using 1994 inventory reports.

Note that chemicals used as pesticides, food additive, drugs and cosmetics are not included in EPA's HPV list.

Consumer Products

that contain ETHYL ACETATE (141-78-6) from Scorecard

What kinds of consumer products may contain this chemical?

- Aerosol paint concentrates
- Auto, other transportation, and machinery refinish paints incl primers
- Gravure inks
- Lubricating oils
- Misc. use aromatics
- Miscellaneous paint-related products
- Moisturizing creams
- Nail enamel and polish removers
- Nail enamels and polishes
- Nonstructural caulking compounds and sealants
- Other automotive chemicals
- Other gravure inks
- Other indust. product finishes excl. pigment dispersions & ink vehicles
- Other manicuring preparations
- Packaging inks: solvent types
- Packaging inks: solvent types
- Paint thinners
- Peripheral computer equipment
- Premoistened towelettes, incl wipes for babies
- Shoe polishes and cleaners
- Specialty performance sealants
- Synthetic resin and rubber adhesives

Basic Testing to Identify Chemical Hazards

for ETHYL ACETATE (141-78-6) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

The following basic tests to identify chemical hazards have either not been conducted or are not publicly available:

- Carcinogenicity
- Chronic toxicity

More on the importance of basic toxicity testing

Ethyl acetate

CASRN 141-78-6

Contents

I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

I.B. REFERENCE CONCENTRATION FOR CHRONIC INHALATION EXPOSURE (RfC)

II. CARCINOGENICITY ASSESSMENT FOR LIFETIME EXPOSURE

VI. BIBLIOGRAPHY

VII. REVISION HISTORY

VIII. SYNONYMS

0157
Ethyl acetate; CASRN 141-78-6

Health assessment information on a chemical substance is included in IRIS only after a comprehensive review of chronic toxicity data by U.S. EPA health scientists from several Program Offices and the Office of Research and Development. The summaries presented in Sections I and II represent a consensus reached in the review process. Background information and explanations of the methods used to derive the values given in IRIS are provided in the Background Documents.

STATUS OF DATA FOR Ethyl acetate

Category (section)	Status	Last Revised
Oral RfD Assessment (I.A.)	on-line	03/01/1988
Inhalation RfC Assessment (I.B.)	no data	

Carcinogenicity Assessment (II.) no data

_I. CHRONIC HEALTH HAZARD ASSESSMENTS FOR NONCARCINOGENIC EFFECTS

__I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

Substance Name -- Ethyl acetate
CASRN -- 141-78-6
Last Revised -- 03/01/1988

The oral Reference Dose (RfD) is based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. It is expressed in units of mg/kg-day. In general, the RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Please refer to the Background Document for an elaboration of these concepts. RfDs can also be derived for the noncarcinogenic health effects of substances that are also carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.A.1. ORAL RfD SUMMARY

Critical Effect	Experimental Doses*	UF	MF	RfD
Mortality and body weight loss	NOEL: 900 mg/kg/day LOAEL: 3600 mg/kg/day	1000	1	9E-1 mg/kg/day
Rat Oral Subchronic Study				
U.S. EPA, 1986				

---

*Conversion Factors: none

I.A.2. PRINCIPAL AND SUPPORTING STUDIES (ORAL RfD)

U.S. EPA. 1986. Rat oral subchronic study with ethyl acetate. Office of Solid Waste, Washington, DC.

Ethyl acetate is fairly nontoxic [LD50 orally in rats: 11.3 g/kg, (Smyth et al., 1962)] and because of its characteristic fruity odor and pleasant taste when diluted, it is primarily used as fruit essences. Pertinent information regarding the mutagenicity, teratogenicity and carcinogenicity of ethyl acetate could not be located in the available literature. Therefore, the U.S. EPA, Office of Solid Waste, under the RCRA Land Disposal Ban, sponsored the 90-day subchronic study of ethyl acetate with rats. Four groups of rats (30/sex/group) were gavaged daily with 0, 300, 900 and 3600 mg/kg/day of ethyl acetate. Six weeks after the initial dosing, 10 rats/sex were subjected to interim sacrifice while the remaining rats continued on the dosing regimen until the final sacrifice (90 days). This study generated data on weekly body weights and food consumption, clinical signs of toxicity, ophthalmological evaluations, moribundity, mortality, blood and urine chemistry and gross and histopathologic evaluations of target organs. Evaluation of the data indicated that male rats exposed to the high dose (3600 mg/kg/day) of ethyl acetate showed significant toxic effects, which resulted in depressed body and organ weights, and depressed food consumption. Female rats exposed to the high dose showed slight but nonsignificant depression of above parameters compared with controls. The next lower dose (900 mg/kg/day) did not produce any adverse effects in either male or female rats and is, therefore, considered a NOEL. By applying an uncertainty factor of 1000 to this NOEL of 900 mg/kg/day, an RfD of 0.9 mg/kg/day or 63 mg/day for a 70-kg person can be recommended.

I.A.3. UNCERTAINTY AND MODIFYING FACTORS (ORAL RfD)

UF -- An uncertainty factor of 1000 is applied: 10 for intra- and 10 for interspecies extrapolation, and 10 to extrapolate subchronic to chronic exposure.

MF -- None

I.A.4. ADDITIONAL COMMENTS (ORAL RfD)

None.

___I.A.5. CONFIDENCE IN THE ORAL RfD

Study -- High
Data Base -- Low
RfD -- Low

The principal study is a well-designed oral study that includes several toxicologic endpoints; high confidence in the study is recommended. The data base did not provide information on additional subchronic/chronic or reproductive toxicity studies; therefore, low confidence is recommended. Confidence in the RfD can be considered low to medium.

ICSC # 0367
UN # 1173
EC # 607-022-00-5

TYPES OF HAZARD/ EXPOSURE	ACUTE HAZARDS/ SYMPTOMS	PREVENTION	FIRST AID/ FIRE FIGHTING
FIRE	Highly flammable.	NO open flames, NO sparks, and NO smoking.	AFFF, alcohol-resistant foam, powder, carbon dioxide.
EXPLOSION	Vapour/air mixtures are explosive.	Closed system, ventilation, explosion-proof electrical equipment and lighting. Use non-sparking handtools.	In case of fire: keep drums, etc., cool by spraying with water.
EXPOSURE		PREVENT GENERATION OF MISTS!	
• **INHALATION**	Cough. Dizziness. Drowsiness. Headache. Nausea. Sore throat. Unconsciousness. Weakness.	Ventilation, local exhaust, or breathing protection.	Fresh air, rest. Artificial respiration if indicated. Refer for medical attention.
• **SKIN**	Dry skin.	Protective gloves. Protective clothing.	Remove contaminated clothes. Rinse skin with plenty of water or shower. Refer for medical attention.
• **EYES**	Redness. Pain.	Safety goggles, or eye protection in combination with breathing protection.	First rinse with plenty of water for several minutes (remove contact lenses if easily possible), then take to a doctor.
• **INGESTION**		Do not eat, drink, or smoke during work.	Rinse mouth. Give plenty of water to drink.

SPILLAGE DISPOSAL	STORAGE	PACKAGING & LABELLING
Evacuate danger area! Collect leaking and spilled liquid in sealable containers as far as possible. Absorb remaining liquid in sand or inert absorbent and remove to safe place. Do NOT wash away into sewer (extra personal protection: complete protective clothing including self-contained breathing apparatus).	Fireproof. Separated from strong oxidants. Cool. Well closed. ICSC: 0367

Prepared in the context of cooperation between the International Programme on Chemical Safety & the Commission of the European Communities © IPCS CEC 1993 No modifications to the International version have been made except to add the OSHA PELs, NIOSH RELs and IDLH values.

International Chemical Safety Cards

ETHYL ACETATE

ICSC: 0367

IMPORTANT DATA

PHYSICAL STATE; APPEARANCE:
COLOURLESS LIQUID , WITH CHARACTERISTIC ODOUR.

PHYSICAL DANGERS:
The vapour is heavier than air and may travel along the ground; distant ignition possible.

CHEMICAL DANGERS:
Heating may cause violent combustion or explosion. The substance decomposes under influence of UV light, bases, acids. Reacts with strong oxidants, bases or acids. Attacks aluminium and plastics.

OCCUPATIONAL EXPOSURE LIMITS (OELs):
TLV: 400 ppm; 1440 mg/m^3 A4 (ACGIH 1997).
OSHA PEL: TWA 400 ppm (1400 mg/m^3)
NIOSH REL: TWA 400 ppm (1400 mg/m^3)
NIOSH IDLH: 2000 ppm LEL

ROUTES OF EXPOSURE:
The substance can be absorbed into the body by inhalation of its vapour.

INHALATION RISK:
A harmful contamination of the air can be reached rather quickly on evaporation of this substance at 20°C.

EFFECTS OF SHORT-TERM EXPOSURE:
The substance irritates the eyes and the respiratory tract. The substance may cause effects on the central nervous system. Exposure far above the OEL may result in death.

EFFECTS OF LONG-TERM OR REPEATED EXPOSURE:
The liquid defats the skin.

PHYSICAL PROPERTIES	Boiling point: 77°C Melting point: -84°C Relative density (water = 1): 0.9 Solubility in water: very good Vapour pressure, kPa at 20°C: 10	Relative vapour density (air = 1): 3.0 Flash point: -4°C c.c. Auto-ignition temperature: 427°C Explosive limits, vol% in air: 2.2-11.5 Octanol/water partition coefficient as log Pow: 0.73
ENVIRONMENTAL DATA		

N O T E S

Use of alcoholic beverages enhances the harmful effect. Acetidin, Vinegar naphtha are trade names.

Transport Emergency Card: TEC (R)-76
NFPA Code: H1; F3; R0;

ADDITIONAL INFORMATION

ICSC: 0367 **ETHYL ACETATE**

© IPCS, CEC, 1993

IMPORTANT LEGAL NOTICE:	Neither NIOSH, the CEC or the IPCS nor any person acting on behalf of NIOSH, the CEC or the IPCS is responsible for the use which might be made of this information. This card contains the collective views of the IPCS Peer Review Committee and may not reflect in all cases all the detailed requirements included in national legislation on the subject. The user should verify compliance of the cards with the relevant legislation in the country of use. The only modifications made to produce the U.S. version is inclusion of the OSHA PELs, NIOSH RELs and IDLH values.

NTP CHEMICAL REPOSITORY (RADIAN CORPORATION, AUGUST 29, 1991)
ETHYL ACETATE

-IDENTIFIERS
 ===========

*CATALOG ID NUMBER: 001668

*CAS NUMBER: 141-78-6

*BASE CHEMICAL NAME: ETHYLACETATE

*PRIMARY NAME: ETHYL ACETATE

*CHEMICAL FORMULA: C4H8O2

*STRUCTURAL FORMULA: CH3COOCH2CH3

*WLN: 2OV1

*SYNONYMS:
  ACETIC ACID, ETHYL ESTER
  ACETIC ETHER
  ACETOXYETHANE
  ETHYL ACETIC ESTER
  ETHYL ETHANOATE
  VINEGAR NAPHTHA
  ACETIDIN
  RCRA WASTE NUMBER U112
  UN 1173

-PHYSICAL CHEMICAL DATA
 ======================

*PHYSICAL DESCRIPTION: LITERATURE: Clear, colorless, mobile liquid
REPOSITORY: Clear colorless liquid

*MOLECULAR WEIGHT: 88.11

*SPECIFIC GRAVITY: 0.9003 @ 20/4 C [016,047,071]

*DENSITY: 0.8945 g/mL [043,062]

*MP (DEG C): -83.6 C [016,043,047,071]

*BP (DEG C): 77 C [031,058,346,451]

*SOLUBILITIES:
WATER : 50-100 mg/mL @ 21 C (RAD)

DMSO : >=100 mg/mL @ 21 C (RAD)

95% ETHANOL : >=100 mg/mL @ 21 C (RAD)

METHANOL : Not available

ACETONE : >=100 mg/mL @ 21 C (RAD)

TOLUENE : Not available

OTHER SOLVENTS:
Alcohol: Soluble [016,031,062,295]
Benzene: Soluble [016,047]
Ether: Soluble [031,205,295,421]
Chloroform: Soluble [031,205,295,421]
Most organic solvents: Miscible [029]

*VOLATILITY:
Vapor pressure: 73 mm Hg @ 20 C [058,062]; 100 mm Hg @ 27 C [038,043,051]
Vapor density : 3.04 [031,043,055,071]

*FLAMMABILITY(FLASH POINT):
This chemical has a flash point of -4 C (24 F) [043,295,371,451]. It is flammable. Fires involving this material can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. The autoignition temperature is 426 C (800 F) [031,062,421,451].

*UEL: 11.5% [031,036,421,451] LEL: 2.0% [058,451]

*REACTIVITY:
This chemical may ignite or explode with lithium aluminum hydride [029,036,066,269]. It may also ignite with potassium tert-butoxide [036,043,066]. It is incompatible with nitrates, strong alkalies and strong acids [102,269,346]. It will attack some forms of plastics, rubber and coatings [102]. It is incompatible with oxidizers such as hydrogen peroxide, nitric acid, perchloric acid and chromium trioxide [058]. Violent reactions occur with chlorosulfonic acid [043,451].

*STABILITY:
This chemical is slowly hydrolyzed by moisture [029,031,269]. It is also sensitive to heat [058,071,102,269]. On prolonged storage, materials containing similar functional groups have formed explosive peroxides [058]. Solutions of this chemical in water, DMSO, 95% ethanol or acetone should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Pleasant, fruity odor [071]
Odor threshold: 50 ppm [071,421]
Refractive index: 1.3723 @ 20 C [016,047]
log P octanol: 0.66-0.73 [055]
Critical temperature: 250 C [371]
Critical pressure: 38 atmospheres [371]
Liquid surface tension: 24 dynes/cm [371]
Evaporation rate (butyl acetate = 1): 4.5 [058]
Latent heat of vaporization: 87.6 cal/g [371]
Heat of combustion: -5816 cal/g [371]
Specific gravity: 0.9019 @ 20/20 C [058]
100% Volatile by volume [058]
Floats on water [058]

-TOXICITY
========

*NIOSH REGISTRY NUMBER: AH5425000

*TOXICITY:

typ. dose	mode	specie	amount	units	other
LCLo	ihl	cat	61	gm/m3	
LCLo	ihl	gpg	77	mg/m3/1H	

TCLo	ihl	hmn	400	ppm
LC50	ihl	mus	45	gm/m3/2H
LC50	ihl	rat	1600	ppm/8H
LD50	ipr	mus	709	mg/kg
LD50	orl	gpg	5500	mg/kg
LD50	orl	mus	4100	mg/kg
LD50	orl	rat	5620	mg/kg
LD50	orl	rbt	4935	mg/kg
LD50	scu	cat	3000	mg/kg
LD50	scu	gpg	3000	mg/kg
LDLo	scu	rat	5000	mg/kg

*AQTX/TLM96: Not available

*SAX TOXICITY EVALUATION:
THR: Moderately irritating to the eyes, mucous membranes, gums and respiratory tract. Prolonged inhalation can cause renal or hepatic damage. Prolonged contact can cause conjunctival irritation and corneal clouding. Poison by inhalation. Moderately toxic by intraperitoneal route. Mildly toxic by ingestion. Mutagenic data.

*CARCINOGENICITY: Not available

*MUTATION DATA: See RTECS printout for data

*TERATOGENICITY: Not available

*STANDARDS, REGULATIONS & RECOMMENDATIONS:
OSHA: Federal Register (1/19/89) and 29 CFR 1910.1000 Subpart Z
Transitional Limit: PEL-TWA 400 ppm [015,327,545,610]
Final Limit: PEL-TWA 400 ppm [015,545,610]
ACGIH: TLV-TWA 400 ppm [015,415,421,610]
NIOSH Criteria Document: None
NFPA Hazard Rating: Health (H): 1
Flammability (F): 3
Reactivity (R): 0
H1: Materials only slightly hazardous to health (see NFPA for details).
F3: Materials which can be ignited under almost all normal temperature conditions (see NFPA for details).
R0: Materials which are normally stable even under fire exposure conditions and which are not reactive with water (see NFPA for details).

*OTHER TOXICITY DATA:
Skin and Eye Irritation Data:
eye-hmn 400 ppm
Review: Toxicology Review
Standards and Regulations: DOT-Hazard: Flammable liquid; Label: Flammable liquid
Status: EPA Genetox Program 1988, Inconclusive: B subtilis rec assay
EPA TSCA Chemical Inventory, 1986
EPA TSCA Test Submission (TSCATS) Data Base, September 1989
IDLH value: 10000 ppm [058]

-OTHER DATA (Regulatory)
==========

*PROPER SHIPPING NAME (IATA): Ethyl acetate

*UN/ID NUMBER: UN1173

*HAZARD CLASS: 3 SUBSIDIARY RISK: None PACKING GROUP: II

*LABELS REQUIRED: Flammable liquid

*PACKAGING: PASSENGER: PKG. INSTR.: 305, Y305 MAXIMUM QUANTITY: 5 L, 1 L
CARGO : PKG. INSTR.: 307 MAXIMUM QUANTITY: 60 L

*SPECIAL PROVISIONS: None

*USES:
This compound is used in artificial fruit essences and as a solvent for varnishes, aeroplane dopes, coatings, plastics, lacquers, nitrocellulose, smokeless powders, organic synthesis and pharmaceuticals. It is used as an insect fumigant and in the manufacture of artificial leather, photographic film and plates, artificial silks, perfumes and cleaning textiles. It is also a synthetic flavoring substance and adjuvant.

*COMMENTS: Not available

-HANDLING PROCEDURES
==========

*ACUTE/CHRONIC HAZARDS:
This chemical is toxic by inhalation, ingestion or skin absorption [062,071,269]. It is an irritant of the skin, eyes, mucous membranes and respiratory tract. The vapor is heavier than air and can travel a considerable distance to a source of ignition and flash back [058]. When heated to decomposition it emits acrid smoke, irritating fumes and toxic fumes of carbon monoxide and carbon dioxide [043,058,269].

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS:
Permeation Test Results For The Neat (Undiluted) Chemical:
The permeation test results for the neat (undiluted) chemical are given below. The breakthrough times of this chemical are given for each glove type tested. The table is a presentation of actual test results, not specific recommendations or suggestions. Avoid glove types which exhibit breakthrough times of less than the anticipated task time plus an adequate safety factor. If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.

Glove Type	Model Number	Thickness	Breakthrough Time
Butyl rubber	North B-174	0.64 mm	420 min
Nitrile	North LA-142G	0.36 mm	8 min

*RECOMMENDED RESPIRATOR:
When working with this chemical, wear a NIOSH-approved full face chemical cartride respirator equipped with the appropriate organic vapor cartridges. If that is not available, a half face respirator similarly equipped plus airtight goggles can be substituted. However, please note that half face respirators provide a substantially lower level of protection than do full face respirators.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should keep this material in a tightly closed container under an inert atmosphere, and store it in an explosion-proof refrigerator. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you spill this chemical, FIRST REMOVE ALL SOURCES OF IGNITION. Then, use absorbent paper to pick up all liquid spill material. Seal the absorbent paper, as well as any of your clothing which may be contaminated, in a vapor-tight plastic bag for eventual disposal. Wash any surfaces you may have contaminated with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT: Not available

-EMERGENCY PROCEDURES
==========

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. Volatile chemicals have a high risk of being aspirated into the victim's lungs during vomiting which increases the medical problems.
If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a hospital or poison control center. IMMEDIATELY transport the victim to a hospital.
If the victim is convulsing or unconscious, do not give anything by mouth, ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport the victim to a hospital.

*SYMPTOMS:
Symptoms of exposure to this compound include irritation of the eyes, mucous membranes, gums and respiratory tract [043,071]. Irritation of the nasal passages and throat may occur [058]. Skin irritation may also occur [062,269]. Prolonged contact may cause corneal clouding. Prolonged inhalation can cause renal or hepatic damage [043]. Prolonged inhalation may also cause damage to the lungs and heart [099]. Other symptoms include gastrointestinal

disturbances, nausea, headache and vomiting [269]. Exposure may cause narcosis and dermatitis [346]. It may also cause drowsiness, unconsciousness and sleepiness. High concentrations can cause stupor. Repeated or prolonged contact can cause drying of the skin and cracking [058]. Central nervous system depression may occur [295]. Chronic exposure may lead to anemia, leucocytosis, cloudy swelling and fatty degeneration of the viscera [043,071].

HAZARDOUS SUBSTANCE FACT SHEET

Common Name: **ETHYL ACETATE**

CAS Number: 141-78-6
DOT Number: UN 1173

RTK Substance number: 0841
Date: January 1986 Revision: June 1996

HAZARD SUMMARY

* **Ethyl Acetate** can affect you when breathed in and by passing through your skin.
* Exposure to high levels can cause you to feel dizzy, lightheaded, and to pass out.
* Repeated contact can cause drying and cracking of the skin.
* **Ethyl Acetate** can irritate the skin, eyes, nose and throat.
* **Ethyl Acetate** is a FLAMMABLE LIQUID and a FIRE HAZARD.

IDENTIFICATION

Ethyl Acetate is a colorless liquid with a fragrant, fruity odor. It is used as a solvent, a synthetic flavoring substance, and in making perfumes and dyes.

REASON FOR CITATION

* **Ethyl Acetate** is on the Hazardous Substance List because it is regulated by OSHA and cited by ACGIH, NFPA, NIOSH, DOT, HHAG and EPA.
* This chemical is on the Special Health Hazard Substance List because it is **FLAMMABLE.**
* Definitions are provided on page 5.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

The New Jersey Right to Know Act requires most employers to label chemicals in the workplace and requires public employers to provide their employees with information and training concerning chemical hazards and controls. The federal OSHA Hazard Communication Standard, 1910.1200, requires private employers to provide similar training and information to their employees.

* Exposure to hazardous substances should be routinely evaluated. This may include collecting air samples. Under OSHA 1910.20, you have a legal right to obtain copies of sampling results from your employer.
* If you think you are experiencing any work-related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.

---

* **ODOR THRESHOLD = 3.9 ppm**.
* The range of accepted odor threshold values is quite broad. Caution should be used in relying on odor alone as a warning of potentially hazardous exposures.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is **400 ppm** averaged over an 8-hour workshift.

NIOSH: The recommended airborne exposure limit is **400 ppm** averaged over a 10-hour workshift.

ACGIH: The recommended airborne exposure limit is **400 ppm** averaged over an 8-hour workshift.

* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* Wear protective work clothing.
* Wash thoroughly immediately after exposure to **Ethyl Acetate** and at the end of the workshift.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of **Ethyl Acetate** to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to **Ethyl Acetate**:

* **Ethyl Acetate** can irritate the skin, eyes, nose and throat.
* Exposure to high levels can cause you to feel dizzy, lightheaded, and to pass out.

Chronic Health Effects

The following chronic (long-term) health effects can occur at some time after exposure to **Ethyl Acetate** and can last for months or years:

Cancer Hazard

* According to the information presently available to the New Jersey Department of Health and Senior Services, **Ethyl Acetate** has been tested and has not been shown to cause cancer in animals.

Reproductive Hazard

* **Ethyl Acetate** may decrease fertility in males.

Other Long-Term Effects

* Repeated contact can cause drying and cracking of the skin.
* This chemical has not been adequately evaluated to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum-based chemicals have been shown to cause such damage. Effects may include reduced memory and concentration, personality changes (withdrawal, irritability), fatigue, sleep disturbances, reduced coordination, and/or effects on nerves supplying internal organs (autonomic nerves) and/or nerves to the arms and legs (weakness, "pins and needles").

MEDICAL

Medical Testing

Before beginning employment and at regular times after that, for those with frequent or potentially high exposures, the following is recommended:

* Evaluate for brain effects such as changes in memory, concentration, sleeping patterns and mood (especially irritability and social withdrawal), as well as headaches and fatigue. Consider evaluations of the cerebellar, autonomic and peripheral nervous systems. Positive and borderline individuals should be referred for neuropsychological testing.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

Request copies of your medical testing. You have a legal right to this information under OSHA 1910.20.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, **ENGINEERING CONTROLS** are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the controls mentioned above, but is sometimes necessary.

In evaluating the controls present in your workplace, consider: (1) how hazardous the substance is, (2) how much of the substance is released into the workplace and (3) whether harmful skin or eye contact could occur. Special controls should be in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically pump liquid **Ethyl Acetate** from drums or other storage containers to process containers.
* Before entering a confined space where **Ethyl Acetate** may be present, check to make sure that an explosive concentration does not exist.

Good **WORK PRACTICES** can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by **Ethyl Acetate** should change into clean clothing promptly.
* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to **Ethyl Acetate**.
* On skin contact with **Ethyl Acetate**, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted **Ethyl Acetate**, whether or not known skin contact has occurred.

* Do not eat, smoke, or drink where **Ethyl Acetate** is handled, processed, or stored, since the chemical can be swallowed. Wash hands carefully before eating or smoking.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT. However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with **Ethyl Acetate**. Wear solvent-resistant gloves and clothing. Safety equipment suppliers/manufacturers can provide recommendations on the most protective glove/clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.

Eye Protection

* Wear splash-proof chemical goggles when working with liquid, unless full facepiece respiratory protection is worn.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* Where the potential exists for exposures over **400 ppm**, use a MSHA/NIOSH approved full facepiece respirator with an organic vapor cartridge/canister. Increased protection is obtained from full facepiece powered-air purifying respirators.
* If while wearing a filter, cartridge or canister respirator, you can smell, taste, or otherwise detect **Ethyl Acetate**, or in the case of a full facepiece respirator you experience eye irritation, leave the area immediately. Check to make sure the respirator-to-face seal is still good. If it is, replace the filter, cartridge, or canister. If the seal is no longer good, you may need a new respirator.
* Be sure to consider all potential exposures in your workplace. You may need a combination of filters, prefilters, cartridges, or canisters to protect against different forms of a chemical (such as vapor and mist) or against a mixture of chemicals.
* Where the potential for higher exposures exists, use a MSHA/NIOSH approved supplied-air respirator with a full facepiece operated in the positive pressure mode or with a full facepiece, hood, or helmet in the continuous flow mode, or use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in pressure-demand or other positive pressure mode.
* Exposure to **2,000 ppm** is immediately dangerous to life and health. If the possibility of exposures above **2,000 ppm** exists, use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in continuous flow or other positive pressure mode.

HANDLING AND STORAGE

* Prior to working with **Ethyl Acetate** you should be trained on its proper handling and storage.
* **Ethyl Acetate** must be stored to avoid contact with STRONG OXIDIZERS (such as CHLORINE, BROMINE, CHLORINE DIOXIDE and NITRATES); BASES (such as SODIUM HYDROXIDE and POTASSIUM HYDROXIDE); and STRONG ACIDS (such as SULFURIC ACID, HYDROCHLORIC ACID and NITRIC ACID) since violent reactions occur.
* Store in tightly closed containers in a cool, well-ventilated area away from HEAT.
* Sources of ignition, such as smoking and open flames, are prohibited where **Ethyl Acetate** is used, handled, or stored in a manner that could create a potential fire or explosion hazard.
* Metal containers involving the transfer of **Ethyl Acetate** should be grounded and bonded. Drums must be equipped with self-closing valves, pressure vacuum bungs, and flame arresters.
* Use only non-sparking tools and equipment, especially when opening and closing containers of **Ethyl Acetate**.
* Store in containers that are properly labeled with health hazard information and safe handling procedures.
* Wherever **Ethyl Acetate** is used, handled, manufactured, or stored, use explosion-proof electrical equipment and fittings.

QUESTIONS AND ANSWERS

Q: If I have acute health effects, will I later get chronic health effects?

A: Not always. Most chronic (long-term) effects result from repeated exposures to a chemical.

Q: Can I get long-term effects without ever having short-term effects?

A: Yes, because long-term effects can occur from repeated exposures to a chemical at levels not high enough to make you immediately sick.

Q: What are my chances of getting sick when I have been exposed to chemicals?
A: The likelihood of becoming sick from chemicals is increased as the amount of exposure increases. This is determined by the length of time and the amount of material to which someone is exposed.

Q: When are higher exposures more likely?
A: Conditions which increase risk of exposure include physical and mechanical processes (heating, pouring, spraying, spills and evaporation from large surface areas such as open containers), and "confined space" exposures (working inside vats, reactors, boilers, small rooms, etc.).

Q: Is the risk of getting sick higher for workers than for community residents?
A: Yes. Exposures in the community, except possibly in cases of fires or spills, are usually much lower than those found in the workplace. However, people in the community may be exposed to contaminated water as well as to chemicals in the air over long periods. Because of this, and because of exposure of children or people who are already ill, community exposures may cause health problems.

Q: Can men as well as women be affected by chemicals that cause reproductive system damage?
A: Yes. Some chemicals reduce potency or fertility in both men and women. Some damage sperm and eggs, possibly leading to birth defects.

The following information is available from:

New Jersey Department of Health and
Senior Services
Occupational Disease and Injury Services
Trenton, NJ 08625-0360
(609) 984-1863

Industrial Hygiene Information

Industrial hygienists are available to answer your questions regarding the control of chemical exposures using exhaust ventilation, special work practices, good housekeeping, good hygiene practices, and personal protective equipment including respirators. In addition, they can help to interpret the results of industrial hygiene survey data.

Medical Evaluation

If you think you are becoming sick because of exposure to chemicals at your workplace, you may call a Department of Health and Senior Services physician who can help you find the services you need.

Public Presentations

Presentations and educational programs on occupational health or the Right to Know Act can be organized for labor unions, trade associations and other groups.

Right to Know Information Resources

The Right to Know Infoline (609) 984-2202 can answer questions about the identity and potential health effects of chemicals, list of educational materials in occupational health, references used to prepare the Fact Sheets, preparation of the Right to Know survey, education and training programs, labeling requirements, and general information regarding the Right to Know Act. Violations of the law should be reported to (609) 984-2202.

DEFINITIONS

ACGIH is the American Conference of Governmental Industrial Hygienists. It recommends upper limits (called TLVs) for exposure to workplace chemicals.

A **carcinogen** is a substance that causes cancer.

The **CAS number** is assigned by the Chemical Abstracts Service to identify a specific chemical.

A **combustible** substance is a solid, liquid or gas that will burn.

A **corrosive** substance is a gas, liquid or solid that causes irreversible damage to human tissue or containers.

DEP is the New Jersey Department of Environmental Protection.

DOT is the Department of Transportation, the federal agency that regulates the transportation of chemicals.

EPA is the Environmental Protection Agency, the federal agency responsible for regulating environmental hazards.

A **fetus** is an unborn human or animal.

A **flammable** substance is a solid, liquid, vapor or gas that will ignite easily and burn rapidly.

The **flash point** is the temperature at which a liquid or solid gives off vapor that can form a flammable mixture with air.

HHAG is the Human Health Assessment Group of the federal EPA.

IARC is the International Agency for Research on Cancer, a scientific group that classifies chemicals according to their cancer-causing potential.

A **miscible** substance is a liquid or gas that will evenly dissolve in another.

mg/m^3 means milligrams of a chemical in a cubic meter of air. It is a measure of concentration (weight/volume).

MSHA is the Mine Safety and Health Administration, the federal agency that regulates mining. It also evaluates and approves respirators.

A **mutagen** is a substance that causes mutations. A **mutation** is a change in the genetic material in a body cell. Mutations can lead to birth defects, miscarriages, or cancer.

NAERG is the North American Emergency Response Guidebook. It was jointly developed by Transport Canada, the United States Department of Transportation and the Secretariat of Communications and Transportation of Mexico. It is a guide for first responders to quickly identify the specific or generic hazards of material involved in a transportation incident, and to protect themselves and the general public during the initial response phase of the incident.

NCI is the National Cancer Institute, a federal agency that determines the cancer-causing potential of chemicals.

NFPA is the National Fire Protection Association. It classifies substances according to their fire and explosion hazard.

NIOSH is the National Institute for Occupational Safety and Health. It tests equipment, evaluates and approves respirators, conducts studies of workplace hazards, and proposes standards to OSHA.

NTP is the National Toxicology Program which tests chemicals and reviews evidence for cancer.

OSHA is the Occupational Safety and Health Administration, which adopts and enforces health and safety standards.

PEOSHA is the Public Employees Occupational Safety and Health Act, a state law which sets PELs for New Jersey public employees.

ppm means parts of a substance per million parts of air. It is a measure of concentration by volume in air.

A **reactive** substance is a solid, liquid or gas that releases energy under certain conditions.

A **teratogen** is a substance that causes birth defects by damaging the fetus.

TLV is the Threshold Limit Value, the workplace exposure limit recommended by ACGIH.

The **vapor pressure** is a measure of how readily a liquid or a solid mixes with air at its surface. A higher vapor pressure indicates a higher concentration of the substance in air and therefore increases the likelihood of breathing it in.

>>>>>>>>>>>>>>>>> EMERGENCY INFORMATION <<<<<<<<<<<<<<<<<

Common Name: **ETHYL ACETATE**
DOT Number: **UN 1173**
NAERG Code: **129**
CAS Number: **141-78-6**

Hazard rating	NJDHSS	NFPA
FLAMMABILITY	-	3
REACTIVITY	-	0
POISONOUS GASES ARE PRODUCED IN FIRE CONTAINERS MAY EXPLODE IN FIRE		

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* **Ethyl Acetate** is a FLAMMABLE LIQUID.
* Use dry chemical, CO_2, or alcohol foam extinguishers. Water can be used to keep fire-exposed containers cool.
* POISONOUS GASES ARE PRODUCED IN FIRE.
* CONTAINERS MAY EXPLODE IN FIRE.
* Vapors may travel to a source of ignition and flash back.
* The vapor is heavier than air and may travel a distance to cause a fire or explosion far from the source.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If **Ethyl Acetate** is spilled or leaked, take the following steps:

* Restrict persons not wearing protective equipment from area of spill or leak until clean-up is complete.
* Remove all ignition sources.
* Ventilate area of spill or leak.
* Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
* Keep **Ethyl Acetate** out of a confined space, such as a sewer, because of the possibility of an explosion, unless the sewer is designed to prevent the build-up of explosive concentrations.
* It may be necessary to contain and dispose of **Ethyl Acetate** as a HAZARDOUS WASTE. Contact your state Department of Environmental Protection (DEP) or your regional office of the federal Environmental Protection Agency (EPA) for specific recommendations.
* If employees are required to clean-up spills, they must be properly trained and equipped. OSHA 1910.120(q) may be applicable.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department. You can request emergency information from the following:

CHEMTREC: (800) 424-9300
NJDEP HOTLINE: (609) 292-7172

==========

HANDLING AND STORAGE (See page 3)

FIRST AID

In NJ, POISON INFORMATION 1-800-962-1253

Eye Contact

* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids.

Skin Contact

* Remove contaminated clothing. Wash contaminated skin with soap and water.

Breathing

* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

PHYSICAL DATA

Vapor Pressure: 76 mm Hg at 68^{o}F (20^{o}C)
Flash Point: 24^{o}F (-4.4^{o}C)

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

Cardiovascular or Blood Toxicity Definition

from the Health Effects section of Scorecard

Cardiovascular and blood toxicity is defined as adverse effects on the cardiovascular or hematopoietic systems that result from exposure to chemical substances. The cardiovascular system is composed of the heart and blood vessels; the hematopoietic system is composed of various blood cell types: erythrocytes (red blood cells), leukocytes (white blood cells), and platelets. Exposure to cardiovascular toxicants can contribute to a variety of diseases, including elevated blood pressure (hypertension), hardening of the arteries (arteriosclerosis), abnormal heartbeat (cardiac arrhythmia),and decreased blood flow to the heart (coronary ischemia). Exposure to hematopoietic toxicants can reduce the oxygen carrying capacity of red blood cells, disrupt important immunological processes carried out by white blood cells, and induce cancer.

Because the cardiovascular system is complex, adverse effects resulting from exposure to chemicals can arise through a variety of mechanisms. Toxicants can contribute to cardiovascular disease by directly damaging cardiac and blood vessel tissue, initiating arteriosclerotic plaque formation, stimulating the inflammatory response, or causing kidney-related hypertension. Lead, carbon disulfide, arsenic, cadmium, ozone, and vinyl chloride have been implicated in the etiology of cardiovascular disease. These chemicals may produce functional changes, such as cardiac arrhythmias, that can have serious and often lethal consequences. They can also induce hypertension, a major cause of cardiac hypertrophy and heart failure. Several toxicants have been found to aggravate preexisting cardiovascular disease. Carbon disulfide and arsenic can irreversibly accelerate coronary heart disease.

The blood cells of the hematopoietic system can also be severely affected by chemical substances. For example, benzene, a component of motor fuel, is a hematopoietic toxin. Chronic exposure to benzene vapors leads to the decreased production of all types of blood cells (pancytopenia). The long-term effect of exposure to benzene is leukemia, a cancerous proliferation of white blood cells.

Developmental Toxicity Definition

from the Health Effects section of Scorecard

Developmental toxicity is defined as adverse effects on the developing child that result from exposure to chemical substances. Sometimes called teratogens, developmental toxicants include agents that induce structural malformations and other birth defects, low birth weight, metabolic or biological dysfunction, and psychological or behavioral deficits that become manifest as the child grows. Developmental toxicity is often considered to be a subcategory of reproductive toxicity, but is treated as a distinct health endpoint in EDF's hazard identification system (see the separate definition of reproductive toxicity).

While developmental toxicity usually results from prenatal exposures to toxicants experienced by the mother, it can also result from paternal exposures, or from postnatal exposures experienced by a developing child. Maternal exposure to toxic chemicals during pregnancy can disrupt the development of or even cause the death of the fetus. Exposure of pregnant women to the developmental toxicant mercury, for example, has been shown to lower the birth weights of and cause severe brain damage in their children. Among the adverse effects associated with maternal exposure to toluene are central nervous system dysfunction, craniofacial and limb anomalies, and developmental delay. Dark brown pigmentation, shorter gestation time, and lower birth weight have been found in the children of women exposed to polychlorinated biphenyls (PCBs) during their pregnancies.

Paternal exposure to toxicants can cause male reproductive toxicity, such as sterility, and may contribute to early fetal loss or birth defects. For example, the occupational exposure of men to vinyl chloride has been associated with increased rates of spontaneous abortion in their wives. Early postnatal contact with toxicants (through contaminated food or air) can affect normal development. Exposure to secondhand tobacco smoke, for example, increases an infant’s risk of contracting respiratory infections or succumbing to sudden infant death syndrome.

Developmental Toxicity References

from the Health Effects section of Scorecard

P65: The most current and authoritative list of chemicals that are recognized to cause developmental toxicity is California's Proposition 65 . Substances are placed on the Proposition 65 list of chemicals "known to the state of California to cause reproductive toxicity" if an independent science advisory board has concluded they possess sufficient evidence of such toxicity in animals or humans, or if an authoritative organization such as the National Toxicology Program have reached a similar conclusion, or if a federal regulatory agency requires a reproductive toxicity warning label. The Proposition 65 list identifies whether a chemical is a developmental toxicant. The current Proposition 65 List of Reproductive Toxicants (February 2001) can be obtained from http://www.oehha.ca.gov/prop65/prop65_list/Newlist.html.

A number of chemicals have toxicological evidence of developmental toxicity that currently does not satisfy the sufficiency criteria used to list agents under Proposition 65, or that has not yet been finally evaluated by hazard identification processes in the state of California or other authoritative agencies. EDF's list of suspect developmental toxicants is compiled from the following sources:

Gastrointestinal or Liver Toxicity Definitions

from the Health Effects section of Scorecard

Gastrointestinal and liver toxicity is defined as adverse effects on the structure and/or functioning of the gastrointestinal tract, liver, or gall bladder that result from exposure to chemical substances. The liver functions as a center for metabolism, processing chemicals we are exposed to so they can be utilized, detoxified, or excreted. While chemicals absorbed from the gastrointestinal tract are always processed by the liver, toxicants that enter the body through other routes of exposure can also reach the liver via its blood supply from the hepatic artery and the portal vein. The liver is frequently subject to injury induced by chemicals, called hepatotoxins, because of its role as the body's principal site of metabolism.

Necrosis, or liver cell death, is a common effect of acute exposure to hepatotoxic chemicals like beryllium, phosphorus, and urethane. The necrosis can be localized in specific areas of the liver or be more widespread. The liver is usually able to recover from necrosis because of its remarkable regenerative capacity. Exposure to hepatotoxic substances can also cause fatty liver (steatosis), hepatitis, jaundice, cholestasis, chronic liver damage (cirrhosis), and cancer. Carbon tetrachloride and related chemicals, such as chloroform, are linked to steatosis, necrosis, and cirrhosis of the liver. The most frequent cause of cirrhosis, however, is the habitual consumption of large quantities of alcohol. Cancer of the liver has been associated with occupational exposures to arsenic, copper, and vinyl chloride.

The gastrointestinal, or digestive, tract is composed of the esophagus, stomach, pancreas, and small and large intestines. The gastrointestinal tract is the site of entry for chemicals that are ingested. Exposure to chemicals that are toxic to the digestive tract can cause anorexia, nausea, vomiting, abdominal cramps, and diarrhea. There are four major types of tissue response to gastrointestinal injury from toxic agents: ulceration, necrosis, inflammation, and proliferation, including cancer. Some chemicals that cause gastrointestinal injury are halogenated aromatic hydrocarbons, including chlorobenzene and hexachlorobenzene, and such metals as lead, mercury, arsenic, and cadmium. Nitrosamines have been shown to cause colon cancer in humans.

Kidney Toxicity Definition

from the Health Effects section of Scorecard

Nephrotoxicity is defined as adverse effects on the kidney, ureter, or bladder that result from exposure to chemical substances. The kidney not only is the major excretory organ in the body, but also performs nonexcretory functions, such as regulating blood pressure and blood volume. Since the kidneys receive approximately 25 percent of cardiac output, any chemical in systemic circulation is delivered to them in relatively high amounts. This makes the kidney unusually susceptible to the toxic effects of chemicals. Some nephrotoxic agents cause acute injury to the kidney, while others produce chronic changes that can lead to end-stage renal failure or cancer. The consequences of renal failure can be profound, sometimes resulting in permanent damage that requires dialysis or kidney transplantation.

Toxic injury to the kidney is known to occur as a result of occupational, accidental, or therapeutic exposure to certain chemicals. Renal toxicants include halogenated hydrocarbons, such as carbon tetrachloride and trichloroethylene, and the heavy metals cadmium and lead.

Reproductive Toxicity Definition

from the Health Effects section of Scorecard

Reproductive toxicity is defined as adverse effects on the male and female reproductive systems that result from exposure to chemical substances. Reproductive toxicity may be expressed as alterations in sexual behavior, decreases in fertility, or loss of the fetus during pregnancy. A reproductive toxicant may interfere with the sexual functioning or reproductive ability of exposed individuals from puberty throughout adulthood. Developmental toxicity (adverse effects on the developing child, such as birth defects) is often considered to be a subcategory of reproductive toxicity, but is treated as a distinct health endpoint in EDF's hazard identification system (see the separate definition of developmental toxicity).

Toxicants that target the female reproductive system can cause a wide variety of adverse effects. Changes in sexual behavior, onset of puberty, cyclicity, fertility, gestation time, pregnancy outcome, and lactation as well as premature menopause are among the potential manifestations of female reproductive toxicity: all can disrupt a woman’s ability to successfully reproduce. Exposure to lead, for example, can result in menstrual disorders and infertility. The toxicants carbon disulfide, mercury, and polychlorinated biphenyls (PBCs) have been shown to cause irregularities in the menstrual cycle. An increased rate of spontaneous abortion has been found in hospital workers exposed to ethylene oxide.

Toxicants that target the male reproductive system can affect sperm count or shape, alter sexual behavior, and/or increase infertility. Carbon disulfide and the pesticides chlordecone (kepone), ethylene dibromide (EDB), and dibromochloropropane (DBCP) are examples of chemicals known to disrupt male reproductive health. These toxicants have lowered the sperm counts of exposed individuals. Occupational exposure to DBCP has caused azoospermia (the total absence of sperm in the semen) and sterility.

For further general information on chemicals and reproductive toxicity, see the following references:

Industrial Uses

for METHYL ETHYL KETONE (78-93-3) from Scorecard

This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.

Which Industries Use This Chemical?	**How is the Chemical Used in This Industry?**
Adhesives Manufacture	Carpet adhesive solvents
Electroplating	Electroplating - Cold-cleaning Solvents
Electroplating	Electroplating - Vapor Degreasing Solvents
Laboratory Chemicals	Solvents - Extraction
Machinery Mfg and Repair	Solvents - Machinery Manufacture and Repair
Metal Degreasing	Solvents - Metal Degreasing
Paint Manufacture	Solvents, Not Elsewhere Classified
Paint Stripping	Solvents - Paint Stripping
Paper Coating	Solvents
Pesticide Mfg (Insecticides)	Solvents - Insecticide Manufacture
Printing	Solvents for Flexography
Printing	Solvents for Gravure Printing
Reprographic Agents	Diazotype Materials - Misc. Chemicals
Rubber Manufacture	Solvents - Rubber Manufacture
Wood Stains and Varnishes	Varnish Solvents

Consumer Products

that contain METHYL ETHYL KETONE (78-93-3) from Scorecard

What kinds of consumer products may contain this chemical?

- Acid nonhousehold metal cleaners (liquid)
- Aerosol paint concentrates
- Architectural coatings
- Auto, other transportation, and machinery refinish paints incl primers
- Automobile body polish and cleaners
- General performance sealants (PVAC, butyl, vinyl, etc.)
- Gravure inks
- Ground/traffic marking coatings
- Household hard surface cleaners (aerosol)
- Household hard surface cleaners (liquid)
- Household tints and dyes
- Industrial particleboard (furniture, fixtures, cabinets, etc.)
- Inks, writing and stamp pad inks (excl drawing and printing inks)
- Laundry starch preparations
- Lubricating oils
- Markers, fine point and broad tipped
- Misc. use aromatics
- Miscellaneous agricultural/pesticidal products
- Miscellaneous paint-related products
- Nail enamel and polish removers
- Nonstructural caulking compounds and sealants
- Other art materials incl clay, water & tempera colors, finger paint, etc.
- Other automotive chemicals
- Other industrial chemical specialty products
- Other manicuring preparations
- Other miscellaneous allied paint products, including brush cleaners
- Other specialty cleaning and sanitation products
- Paint and varnish removers
- Paint thinners
- Shoe polishes and cleaners
- Solvent thinned interior clear finishes
- Solvent thinned interior stains

- Solvent thinned interior undercoaters and primers
- Specialty performance sealants
- Surfactants, finishing agents, and assistants
- Synthetic resin and rubber adhesives
- Waterproofing compounds

Scorecard's Source for Environmental Release and Waste Management Data

from Scorecard

Scorecard's source for information about chemical releases and waste management from manufacturing facilities is the U.S. Environmental Protection Agency's Toxics Release Inventory. The TRI database was established by Section 313 of the Emergency Planning and Community Right-To-Know Act of 1986 (EPCRA).

Under EPCRA, manufacturing facilities in specific industries are required to report their environmental releases and chemical waste management annually to EPA. Covered facilities must disclose their releases of approximately 650 toxic chemicals and chemical categories to air, water, and land, as well as the quantities of chemicals they recycle, treat, burn, or otherwise dispose of on-site and off-site. The specific categories of releases, transfers and overall waste generation reported to TRI are explained by Scorecard's Definitions of Toxics Release Inventory Reporting Categories.

Scorecard's 1998 TRI data is derived from the reports of 23,500 manufacturing and federal facilities. Seven "new" industries (e.g., mining and electric power generation) were required to report their release and waste management data for the first time in 1998, substantially increasing the total amount of chemicals tracked by TRI.

In 1998, facilities reported a total of 7.3 billion pounds of releases to air, land, water and underground injection. "Original" industries (required to report to TRI prior to 1997) reported approximately 2.4 billion pounds, or 32.6%, of the 7.3 billion pounds. Facilities in the new sectors reported almost 4.9 billion pounds, or 67.4%, of the 7.3 billion pounds. Reporting from the new industries accounted for 91.7 % of the land releases on-site, 38.8% of the air releases, 21.2 % of the releases to underground injection wells, and 3.5% of the discharges to surface water.

THE LIMITS OF TRI DATA

While TRI is the most comprehensive national source of information about toxic chemical releases, it has critical limitations:

1) TRI does not cover all toxic chemicals that have the potential to adversely affect human health or the environment.

2) TRI does not require reporting from many major sources of pollution releases.

3) TRI does not require companies to report the quantities of toxic chemicals used or the amounts that remain in products.

4) TRI does not provide information about the exposures people may experience as a consequence of chemical use.

WHAT NEW POLLUTION SOURCES ARE COVERED FOR THE FIRST TIME BY 1998 TRI DATA

Seven "new" industries only began reporting to TRI in 1998, and now dominate most rankings based on environmental releases:

Metal mining
Coal mining
Electric utilities
Commercial hazardous-waste treatment
Petroleum bulk terminals
Chemical wholesalers
Solvent recovery services

SCORECARD'S SOURCE FOR TRI DATA

All environmental release data in Scorecard are derived from the U.S. Environmental Protection Agency's public release of the 1998 TRI database. Issues related to the quality of 1998 TRI data used in Scorecard are explained in How Reliable Are TRI Data?

Basic Testing to Identify Chemical Hazards

for METHYL ETHYL KETONE (78-93-3) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

The following basic tests to identify chemical hazards have either not been conducted or are not publicly available:

- Carcinogenicity

More on the importance of basic toxicity testing

2-Butanone

CAS# 78-93-3

September 1995

2-Butanone
C_4H_8O
Stereo Image
XYZ File

NFPA Label Key

Material Safety Data Sheet
(University of Utah)

Agency for Toxic Substances and Disease Registry

This fact sheet answers the most frequently asked health questions about 2-butanone. For more information, you may call the ATSDR Information Center at 1-800-447-1544. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to 2-butanone occurs in the workplace or from using consumer products containing it. Mild irritations of the eyes, nose, and throat were seen in people who breathed 2-butanone. This chemical has been found in at least 472 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is 2-butanone?
(Pronounced 2-byoo'ta-no-n)

2-Butanone is a manufactured chemical but it is also present in the environment from natural sources. It is a colorless liquid with a sharp, sweet odor. It is also known as methyl ethyl ketone (MEK).

2-Butanone is produced in large quantities. Nearly half of its use is in paints and other coatings because it will quickly evaporate into the air and it dissolves many substances. It is also used in glues and as a cleaning agent.

2-Butanone occurs as a natural product. It is made by some trees and found in some fruits and vegetables in small amounts. It is also released to the air from car and truck exhausts.

What happens to 2-butanone when it enters the environment?

- 2-Butanone enters the air during production, use and transport, and from hazardous waste sites.
- In air, one-half of it will break down from sunlight in 1 day or less.
- It dissolves in water and is broken down more slowly to a simpler chemical form in about 2 weeks.
- It does not stick to soil and will travel through the soil to the groundwater.
- Some of the 2-butanone in soil or water will evaporate into the air.
- It does not deposit in the bottom of rivers or lakes.
- It is not expected to concentrate in fish or increase in the tissues of animals further up the food chain.

How might I be exposed to 2-butanone?

- Breathing contaminated air from the production or use of paints, glues, coatings, or cleaning agents containing it
- Breathing contaminated air near hazardous waste sites
- Breathing cigarette smoke
- Sniffing glues
- Drinking contaminated water from wells near manufacturing or hazardous waste sites
- Skin contact with the liquid during production or use.

How can 2-butanone affect my health?

The known health effects to people from exposure to 2-butanone are irritation of the nose, throat, skin, and eyes. No one has died from breathing 2-butanone alone. If 2-butanone is breathed along with other chemicals that damage health, it can increase the amount of damage that occurs.

Serious health effects in animals have been seen only at very high levels. When breathed, these effects included birth defects, loss of consciousness, and death.

When swallowed, rats had nervous system effects including drooping eyelids and uncoordinated muscle movements. There was no damage to the ability to reproduce.

Mice who breathed low levels for a short time showed temporary behavioral effects. Mild kidney damage was seen in animals that drank water with lower levels of 2-butanone for a short time.

There are no long-term studies with animals either breathing or drinking 2-butanone.

How likely is 2-butanone to cause cancer?

The Department of Health and Human Services has not classified 2-butanone as to its human

carcinogenicity.

The International Agency for Research on Cancer and the Environmental Protection Agency (EPA) have also not classified 2-butanone as to its human carcinogenicity.

Two studies of workers exposed to 2-butanone and other chemicals did not find an increase in cancer. No animal studies are available that examine the potential for 2-butanone to cause cancer.

Is there a medical test to show whether I've been exposed to 2-butanone?

Tests are available to measure 2-butanone or its breakdown products in blood, breath, and urine. These tests are useful only to measure recent exposures because 2-butanone and its breakdown products leave the body rapidly. These tests are not usually performed at your doctor's office, but your doctor can take blood or urine samples and send them to a testing laboratory.

Has the federal government made recommendations to protect human health?

The EPA requires that discharges or spills into the environment of 5,000 pounds of more of 2-butanone be reported.

The Occupational Safety and Health Administration (OSHA) set an occupational exposure limit of 200 parts of 2-butanone per million parts of workplace air (200 ppm) for an 8-hour workday, 40-hour workweek.

The American Conference of Governmental Industrial Hygienists (ACGIH) and the National Institute for Occupational Safety and Health (NIOSH) have established the same guidelines as OSHA for the workplace.

Glossary

Carcinogenicity:

Ability to cause cancer.

Evaporate:

To change into a vapor or a gas.

PPM:

Parts per million.

Long-term:

Lasting one year or longer.

Short time:

Lasting 14 days or less.

Where can I get more information?

ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can

recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

METHYL ETHYL KETONE

Methyl ethyl ketone is a federal hazardous air pollutant and was identified as a toxic air contaminant in April 1993 under AB 2728.

CAS Registry Number: 78-93-3

Structure: $C_2H_5COCH_3$

Molecular Formula: C_4H_8O

Description

Methyl ethyl ketone is a flammable, colorless liquid with an acetone-like, sweet, pungent odor. It is soluble in four parts water and miscible with alcohol, ether, acetone, and benzene. It is lighter than water and may be expected to float while rapidly dissolving (HSDB, 1991).

Physical Properties of Methyl Ethyl Ketone

Molecular Weight	72.10
Boiling Point	79.6 oC
Melting Point	-86.35 oC
Flash Point:	-6 oC (21 oF) (closed cup)
Vapor Pressure	90.6 mm Hg at 25 oC
Vapor Density	2.41 (air = 1)
Density/Specific Gravity	0.805 at -20/4 oC (water = 1)
Log/Octanol Partition Coefficient	0.29
Henry's Law Constant	1.05 x 10-5 atm-m3/mole
Conversion Factor	1 ppm = 2.95 mg/m3

(HSDB, 1991; Merck, 1989; Sax, 1989; U.S. EPA, 1994a)

SOURCES AND EMISSIONS

A. Sources

Methyl ethyl ketone is used as a solvent for lacquers, adhesives, rubber cement, printing inks, and paint removers, in cleaning solutions, as a catalyst, and as a carrier. Cigarette smoke and gasoline exhaust are also sources of methyl ethyl ketone. Methyl ethyl ketone has been detected or quantified in motor vehicle exhaust by the Air Resources Board (ARB) (ARB, 1995e).

The primary stationary sources that have reported emissions of methyl ethyl ketone in California are

millwork, veneer, and plywood manufacturers, manufacturers of wood furniture, and manufacturers of rubber and plastic footwear (ARB, 1997b).

B. Emissions

The total emissions of methyl ethyl ketone from stationary sources in California are estimated to be at least 290,000 pounds per year, based on data reported under the Air Toxics "Hot Spots" Program (AB 2588) (ARB, 1997b).

C. Natural Occurrence

Methyl ethyl ketone occurs naturally in volcanos, forest fires, products of biological degradation, and is a natural component of food (Howard, 1990).

AMBIENT CONCENTRATIONS

Methyl ethyl ketone is routinely monitored by the Air Resources Board statewide air toxics network. The network's mean concentration of methyl ethyl ketone from January 1996 to December 1996 is estimated to be 0.32 micrograms per cubic meter (µg/m3) or 0.11 parts per billion (ppb) (ARB, 1997c).

The United States Environmental Protection Agency (U.S. EPA) has also compiled ambient concentration data for methyl ethyl ketone from several locations throughout the United States from 1972-87. A mean ambient concentration of 1.4 µg/m3 (0.47 ppb) was derived from these data (U.S. EPA, 1993a).

INDOOR SOURCES AND CONCENTRATIONS

No information about the indoor sources and concentrations of methyl ethyl ketone was found in the readily-available literature.

ATMOSPHERIC PERSISTENCE

If released to the atmosphere, methyl ethyl ketone will exist primarily in the gas phase. The dominant tropospheric loss process of methyl ethyl ketone appears to be reaction with the hydroxyl (OH) radical, with photolysis being unimportant. The calculated half-life and lifetime of methyl ethyl ketone due to reaction with the OH radical are 9 days and 13 days, respectively. The products of the OH radical reaction are acetaldehyde, formaldehyde and, in the presence of nitrogen dioxide (NO2), peroxyacetyl nitrate (PAN) (Atkinson, 1994).

AB 2588 RISK ASSESSMENT INFORMATION

Although methyl ethyl ketone is reported as being emitted in California from stationary sources no health values (cancer or non-cancer) are listed in the California Air Pollution Control Officers Association Air

Toxics "Hot Spots" Program Revised 1992 Risk Assessment Guidelines for use in risk assessments (CAPCOA, 1993).

HEALTH EFFECTS

Probable routes of human exposure to methyl ethyl ketone are inhalation, ingestion, and dermal contact (Sittig, 1991).

Non-Cancer: Exposure to methyl ethyl ketone vapors can cause eyes, nose, throat, and respiratory tract irritation. Methyl ethyl ketone is a central nervous system depressant. Methyl ethyl ketone enhances the neurotoxicity of n-hexane (U.S. EPA, 1994a).

The U.S. EPA has established a Reference Concentration (RfC) of 1.0 milligram per cubic meter for methyl ethyl ketone, based on decreased fetal birth weight in mice. The U.S. EPA estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic, non-cancer effects. The U.S. EPA has established an oral Reference Dose (RfD) for methyl ethyl ketone of 0.6 milligrams per kilogram per day, based on decreased fetal birth weights in rats. The U.S. EPA estimates that consumption of this dose or less, over a lifetime, would not likely result in the occurrence of chronic, non-cancer effects (U.S. EPA, 1994a).

No information was located on adverse reproductive effects of methyl ethyl ketone in humans. Retardation of fetal development and fetal malformations were reported in mice exposed to methyl ethyl ketone by inhalation (U.S. EPA, 1994a).

Cancer: No information is available regarding carcinogenic effects in humans from exposure to methyl ethyl ketone. The U.S. EPA has placed methyl ethyl ketone in Group D: Not classifiable as a carcinogen, based on lack of data in humans and animals (U.S. EPA, 1994a). The International Agency for Research on Cancer has not classified methyl ethyl ketone for carcinogenicity (IARC, 1987a).

METHYL ETHYL KETONE

Hazard Summary

CAUTION: Unless otherwise noted, the quantitative information on these fact sheets are from "EPA Health Effects Notebook for Hazardous Air Pollutants-Draft", EPA-452/D-95-00, PB95-503579, December 1994." Please conduct a current literature search and check the appropriate current online database for the most recent quantitative information.

- Acute (short-term) exposure to methyl ethyl ketone in humans, via inhalation, results in **irritation to the eyes, nose, and throat, and central nervous system depression.**
- Limited information is available on the chronic (long-term) effects of methyl ethyl ketone in humans. Chronic inhalation studies in animals have reported effects on the central nervous system, liver, and respiratory system.
- The Reference Concentration (RfC) for methyl ethyl ketone is 1.0 mg/m^3.[a] The U.S. Environmental Protection Agency (EPA) estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic, noncancer effects.[b]
- The Reference Dose (RfD) for methyl ethyl ketone is 0.6 mg/kg/d.[c] EPA estimates that consumption of this level or less, over a lifetime, would not likely result in the occurrence of chronic, noncancer effects.
- No information is available on the developmental or reproductive effects of methyl ethyl ketone in humans. **Reduction of fetal development and fetal malformations** has been reported in mice exposed to methyl ethyl ketone in the air.
- Limited data are available on the carcinogenic effects of methyl ethyl ketone. No human data are available and the only available animal study did not report skin tumors from dermal exposure to methyl ethyl ketone. EPA has classified methyl ethyl ketone as a Group D, **not classifiable as to human carcinogenicity.**

---

[a] Milligrams per cubic meter is the unit of measurement for chemicals in air.

[b] The RfC is not a direct estimator of risk, but rather a reference point to gauge the potential effects. Exceedance of the RfC does not imply that an adverse health effect would necessarily occur. As the amount and frequency of exposures exceeding the RfC increase, the probability that adverse health effects may be seen also increases.

[c] Milligrams per kilogram per day is one way to measure the amount of the contaminant that is consumed in food.

Please Note: The main sources of information for this fact sheet are EPA's *Health Effects Assessment for Methyl Ethyl Ketone* and EPA's Integrated Risk Information System (IRIS), which contains information on inhalation chronic toxicity of methyl ethyl ketone and the RfC and oral chronic toxicity and the RfD. Other secondary sources include the Hazardous Substances Data Bank (HSDB), a database of summaries of peer-reviewed literature, and the Registry of Toxic Effects of Chemical Substances (RTECS), a database of toxic effects that are not peer reviewed.

Environmental/Occupational Exposure

- Methyl ethyl ketone has been detected in both indoor and outdoor air. Methyl ethyl ketone can be produced in outdoor air by the photooxidation of certain air pollutants, such as butane and other hydrocarbons. (1)
- Methyl ethyl ketone has been found in drinking water and surface water at a number of sites. (2)
- Exposure to methyl ethyl ketone could also occur at the workplace and through exposure to household products containing the chemical. (1)

Assessing Personal Exposure

- Levels of methyl ethyl ketone in the urine can be measured to determine exposure to the chemical. (1)

Health Hazard Information

Acute Effects:

- Acute exposure to high concentrations of methyl ethyl ketone in humans produces irritation to the eyes, nose, and throat. (1,3,4)
- Other effects reported from acute inhalation exposure in humans include central nervous system depression, headache, and nausea. (1,3,4)
- Dermatitis has been reported in humans following dermal exposure to methyl ethyl ketone. (1)
- Tests involving acute exposure of animals, such as the LD_{50} test in rabbits, has shown methyl ethyl ketone to have high acute toxicity from dermal exposure, while the LD_{50} test in rats and mice has shown the chemical to have moderate toxicity from ingestion. (5)
- The LC_{50} test in rats has indicated low toxicity from methyl ethyl ketone exposure via inhalation. (5)

Chronic Effects (Noncancer):

- Limited information is available on the chronic effects of methyl ethyl ketone in humans from inhalation exposure. One study reported nerve damage in individuals who sniffed a glue thinner containing methyl ethyl ketone and other chemicals. (1)

- Slight effects on the central nervous system, liver, and respiratory system have been reported in chronic inhalation studies of methyl ethyl ketone in animals. (1)
- The RfC for methyl ethyl ketone is 1 mg/m^3 based on decreased fetal birth weight in mice. (6)
- EPA has medium confidence in the principal study on which the RfC is based because it is well designed and tested several exposure concentrations and several endpoints of toxicity although there are insufficient data presented for possible respiratory effects; low confidence in the database because there are no multigenerational studies and only one subchronic study and portal-of-entry effects are not adequately address; and, consequently, confidence in the RfC is low. (6)
- The RfD for methyl ethyl ketone is 0.6 mg/kg/d based on decreased fetal birth weight in rats. (6)
- EPA has low confidence in the study on which the RfD is based because lowering the high-dose group from 3.0 to 2.0% confounded determination of the critical effect; low confidence in the database because of the lack of oral data for MEK itself and the absence of data in a second species; and, consequently, low confidence in the RfD. (6)
- EPA's Office of Air Quality Planning and Standards, for a hazard ranking under Section 112(g) of the Clean Air Act Amendments, has evaluated methyl ethyl ketone for chronic toxicity and has given it a composite score of 10 (scores range from 1 to 100, with 100 being the most toxic). These scores are nonlinear and are the product of two ratings: a rating based on the minimal-effect dose and a rating based on the type of effect. (9)

Reproductive/Developmental Effects:

- No information on the reproductive or developmental effects of methyl ethyl ketone in humans was located.
- An inhalation study in mice reported retardation of fetal development and fetal malformations in animals exposed to methyl ethyl ketone. (4)

Cancer Risk:

- No information on the carcinogenicity of methyl ethyl ketone in humans was located.
- No studies were available on the carcinogenicity of methyl ethyl ketone by the oral or inhalation routes. In a dermal carcinogenicity study, skin tumors were not reported from methyl ethyl ketone exposure. (1,6)
- EPA has classified methyl ethyl ketone as a Group D, not classifiable as to human carcinogenicity, based on a lack of data concerning carcinogenicity in humans and animals. (6)

Physical Properties

- Methyl ethyl ketone is a colorless volatile liquid that is soluble in water. (2)
- The odor threshold for methyl ethyl ketone is 5.4 ppm, with an acetone-like odor reported. (8)
- The chemical formula for methyl ethyl ketone is C_4H_8O and the molecular weight is 72.10 g/mol. (9)
- The vapor pressure for methyl ethyl ketone is 95.1 mm Hg at 25 C, and it has a log octanol/water partition coefficient (Log K_{ow}) of 0.261. (9)

Uses

- The primary use of methyl ethyl ketone is as a solvent in processes involving gums, resins, cellulose acetate, and cellulose nitrate. (1)
- Methyl ethyl ketone is also used in the synthetic rubber industry, in the production of paraffin wax, and in household products such as lacquer and varnishes, paint remover, and glues. (1)

Conversion Factors:
To convert from ppm to mg/m^3: mg/m^3 = (ppm) × (molecular weight of the compound)/(24.45). For methy ethyl ketone: 1 ppm = 2.95 mg/m^3.

Health Data from Inhalation Exposure

Concentration (mg/m^3)	Health numbers[a]	Regulatory, advisory numbers[b]	Reference
100,000.0			
-- -- -- -- 10,000.0	• LC_{50} (rat) (23,500 mg/m^3)		5
-- -- -- -- 1,000.0	• LOAEL (mice) (8,906 mg/m^3)[c] • NOAEL (mice) (2,978 mg/m^3)[c]		6 6

-- -- -- -- 10.0			
-- -- -- -- 1.0	• RfC (1 mg/m^3)		6

ACGIH STEL--American Conference of Governmental and Industrial Hygienists' short-term exposure

limit: 15-min time-weighted-average exposure that should not be exceeded at any time during a workday even if the 8-h time-weighted-average is within the threshold limit value.
ACGIH TLV--American Conference of Governmental and Industrial Hygienists' threshold limit value expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effects.
LC_{50} (Lethal Concentration$_{50}$)--A calculated concentration of a chemical in air to which exposure for a specific length of time is expected to cause death in 50% of a defined experimental animal population.
LOAEL--Lowest-observed-adverse-effect level.
NIOSH REL--National Institute of Occupational Safety and Health's recommended exposure limit; NIOSH-recommended exposure limit for an 8- or 10-h time-weighted-average exposure and/or ceiling.
NOAEL--No-observed-adverse-effect level.
OSHA PEL--Occupational Safety and Health Administration's permissible exposure limit expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effect averaged over a normal 8-h workday or a 40-h workweek.
RfC--Reference concentration.

[a] Health numbers are toxicological numbers from animal testing or risk assessment values developed by EPA.
[b] Regulatory numbers are values that have been incorporated in Government regulations, while advisory numbers are nonregulatory values provided by the Government or other groups as advice.
[c] The LOAEL and NOAEL are from the critical study used as the basis for the EPA RfC.

Health assessment information on a chemical substance is included in IRIS only after a comprehensive review of chronic toxicity data by U.S. EPA health scientists from several Program Offices and the Office of Research and Development. The summaries presented in Sections I and II represent a consensus reached in the review process. Background information and explanations of the methods used to derive the values given in IRIS are provided in the Background Documents.

_I. CHRONIC HEALTH HAZARD ASSESSMENTS FOR NONCARCINOGENIC EFFECTS

__I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

Substance Name -- Methyl ethyl ketone (MEK)
CASRN -- 78-93-3
Last Revised -- 05/01/1993

The oral Reference Dose (RfD) is based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. It is expressed in units of mg/kg-day. In general, the RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Please refer to the Background Document for an elaboration of these concepts. RfDs can also be derived for the noncarcinogenic health effects of substances that are also carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.A.1. ORAL RfD SUMMARY

Critical Effect	Experimental Doses*	UF	MF	RfD
Decreased fetal birth weight	NOAEL: 1771 mg/kg-day (1% 2-butanol solution)	3000	1	6E-1 mg/kg-day
Multigeneration/ Developmental Rat Feeding Study	LOAEL: 3122 mg/kg-day (2% 2-butanol solution)			
Cox et al., 1975				

---

*Conversion Factors and Assumptions: Based on actual consumption data for the

NOAEL and regression analysis for the LOAEL of exposure to 2-butanol, a metabolic intermediate of methyl ethyl ketone.

___I.A.2. PRINCIPAL AND SUPPORTING STUDIES (ORAL RfD)

Cox, G.E., D.E. Bailey and K. Morgareidge. 1975. Toxicity studies in rats with 2-butanol including growth, reproduction and teratologic observations. Food and Drug Research Laboratories, Inc., Waverly, NY, Report No. 91MR R 1673.

The identification of the critical effect for methyl ethyl ketone (MEK), also referred to as 2-butanone, is based on its metabolic intermediate, 2-butanol. A detailed rationale for use of this intermediate of MEK can be found in Additional Comments/Studies.

Weanling FDRL-Wistar stock rats (30/sex/group) were given 2-butanol in drinking water at 0, 0.3, 1.0, or 3.0% solutions and a standard laboratory ration ad libitum. Weekly feed, fluid intakes and body weights were recorded to determine the efficiency of food utilization and to calculate the average daily intake of 2-butanol. The average daily intake of 2-butanol for males was 0, 538, 1644, and 5089 mg/kg-day and for females was 0, 594, 1771, and 4571 mg/kg-day for the 0, 0.3, 1.0, and 3.0% solutions, respectively. At the highest exposure level (3.0%), net weight gain was reduced compared with controls both in males (229 g vs. 269 g in controls) and females (130 g vs. 154 g in controls) during the 8 weeks of initial monitoring. However, no differences were found in the efficiency of food utilization.

After 9 weeks of exposure, parental matings were made with one male and one female from each of the respective treatment groups (P generation). Following birth of the first litter (F1A) of the parental generation, various reproduction and lactation responses were measured. This study design incorporated a multigeneration protocol with measurement of developmental toxicity endpoints. Significant effects were noted in the litters from the 3.0% 2-butanol dose group vs. the control group, including the number of pups/litter cast alive (8.46 vs. 10.3), the number of pups/litter alive at 4 days before culling (8.12 vs. 10.3), the number of pups/litter alive at 21 days (6.85 vs. 7.68), the mean body weight/pup after culling at 4 days (8.2 g vs. 10.3 g) and the mean body weight/pup at 21 days (28.4 g vs. 49.5 g).

Based on results found in the 3.0% (high-dose) 2-butanol F1A generation, the treatment of all high-dose parents and offspring was reduced to 2.0% 2-butanol for the remainder of the experimental protocol. Following a 2-week interim adaptation period to allow the F1A generation animals to attain a more normal weight, the P generation was subsequently remated to produce a second litter (F1B), and the F1A generation selected for an F2 mating. Therefore, a new high dose of 2.0% 2-butanol was calculated to be equivalent to 3384 mg/kg-day in males and 3122 mg/kg-day in females based on regression analysis of the 8 week water intake data. The F1B litters receiving 2.0% 2-butanol showed a slight reduction in average fetal weight compared with controls (3.74 g vs. 4.14 g in controls). Nidation, early fetal deaths, and late fetal deaths were not detectably affected. Skeletal findings also were reported for the F1B

generation. The 2.0% group showed apparent increases in missing sternebrae, wavy ribs, and incomplete vertebrae ossification when compared with both the 0.3 and 1.0% groups. However, because of the rather high incidence in the control group for these findings, these effects could not be determined to be compound-related. The 2.0% group also showed a reduction in the mean body weight per pup at day 4 following culling (9.48 g vs. 10.0 g in the control) and in the mean body weight at 21 days (34.9 vs. 41.1 g in the control). Although these reductions were not as great in the high dose (3.0%) F1A generation, the percent body weight reduction in the F1B high dose (2.0%) was doubled at 21 days (reductions of 5% at 4 days and 11% at 21 days). This generation showed the same doubling trend in fetal weight reduction as was reported in the F1A group exposed to 3.0% 2-butanol throughout (reductions of 21% at 4 days and 43% at 21 days). These results are also presented in abstract form by Gallo et al. (1977).

At the 2.0% level of the F2 generation, there were a number of histopathologic changes noted in the kidney of the male rats only. These changes were characterized by nonreactive tubular degeneration in the outer medullary zone, tubular cast formation, foci of tubular degeneration and regeneration, microcysts in the renal papilla, glomerular fibrosis, and focal epithelial calcification. These findings are consistent with the pattern of early stages of alpha 2u-globulin-associated rat nephrotoxicity as set forth by the Risk Assessment Forum (U.S. EPA, 1991). As per the Agency's guidance, it is not appropriate to use these specie-and sex-specific renal effects to establish a critical effect.

Administration of 2-butanol resulted in the occurrence of developmental effects. Decreased pup survivability and fetal weight were seen in the 3.0% group, and in the F1 offspring (F1A and F1B, whose parents received 3.05 and 2.0% 2-butanol, respectively). The decrease in fetal weight continued to be demonstrated in the F2 generation at the 2.0% level. Therefore, based on these developmental toxicologic endpoints, a LOAEL of 3122 mg/kg-day (2.0% solution) and a NOAEL of 1771 mg/kg-day (1.0% solution) are identified.

___I.A.3. UNCERTAINTY AND MODIFYING FACTORS (ORAL RfD)

UF -- Four uncertainty factors of 10 each were applied, one to account for interspecies extrapolation and intraspecies variability (extrapolation to sensitive human populations); one to adjust for subchronic to chronic extrapolation since long-term effects in the dams during the exposure period were not reported in the principal study; one for incompleteness of the data base, including a lack of both subchronic and chronic oral exposure studies for MEK; and one to account for the absence of data for a second rodent specie for either MEK or 2-butanol. As is usual practice, the application of four full areas of uncertainty generally results in a total uncertainty factor of 3000, given the interrelationship among and overlap between the various areas of uncertainty described above.

MF -- None

I.A.4. ADDITIONAL STUDIES / COMMENTS (ORAL RfD)

Data on toxic effects in humans or laboratory animals following oral exposure to MEK are restricted to a limited number of acute studies. Oral LD50 values for MEK include 5522 and 2737 mg/kg in rats (Smyth et al., 1962 and Kimura et al., 1971, respectively) and 4,044 mg/kg in mice (Tanii et al., 1986). Single gavage doses of 15 mmol/kg MEK in corn oil (1082 mg/kg) produced no deaths or histological alterations in the livers of male Fischer 344 rats, but produced tubular necrosis in kidneys (Brown and Hewitt, 1984). Pre-administration of single gavage doses of MEK (or other ketonic solvents) enhanced the liver and kidney damage produced by a 0.5 mL/kg intraperitoneal dose of carbon tetrachloride (Brown and Hewitt, 1984). This MEK potentiation of carbon tetrachloride hepatotoxicity was also observed in similar experiments with male Sprague-Dawley rats (Dietz and Traiger, 1979).

At present there are insufficient oral exposure data of MEK from which to derive an oral RfD. Availability of oral exposure data of a metabolic intermediate of MEK, i.e., 2-butanol, was used to derive the RfD of MEK. The following is an explanation of the rationale for using the oral data of 2-butanol rather than attempting a route-to-route extrapolation of the available inhalation data for MEK.

Traiger and Bruckner (1976) have estimated that approximately 96% of an administered dose of 2-butanol is oxidized in vivo to MEK. The data from the Dietz et al. (1981) study support this estimation. Administration of 1776 mg/kg 2-butanol by gavage shows peak blood 2-butanol concentrations (0.59 mg/mL) within 2 hours; the compound is barely detectable after 16 hours. As the blood concentrations of 2-butanol fall, the peak concentrations of MEK (0.78 mg/mL) and 2,3-butanediol (0.21 mg/mL) occurred at 8 and 18 hours respectively. Ultimately, 2-butanol and MEK are metabolized through the same intermediates.

Additional metabolism of the ketone occurs by oxidation to hydroxylated intermediates such as 2,3-butanediol, all of which can be eliminated in the urine (DiVincenzo et al., 1977). DiVincenzo et al. (1976) have previously identified MEK, 2-butanol, and other oxidative metabolites of MEK in the serum of guinea pigs following administration of MEK.

A pharmacokinetic model was presented by Dietz et al. (1981) to describe the biotransformation of 2-butanol and MEK in rats when given a dose calculated to produce an equivalent calculated adjusted urinary concentration. When MEK is administered by gavage at a dose of 1690 mg/kg, the detection of the formation of 2-butanol and the oxidative metabolites corresponds to that previously reported in the guinea pig. By 18 hours post administration, MEK is barely detectable in the blood (peak concentration of 0.95 mg/mL at 4 hours), but a peak blood concentration (0.26 mg/mL) of the oxidative metabolite 2,3-butanediol can be detected. Peak blood concentrations of 2-butanol (0.033 mg/mL) occurred after 6 hours.

Although it is not known if the effects reported by Cox et al. (1975) are due to either 2-butanol directly or indirectly through another common metabolite, the weight of evidence of the available data argues for using the

butanol data as a surrogate approach to the development of the RfD for MEK. It is assumed in this surrogate approach that 2-butanol is not the active metabolite causing the effects reported by Cox, given the profile of metabolism for both 2-butanol and MEK. Therefore, it is appropriate to utilize data from the oral administration of 2-butanol in order to derive an RfD for MEK in lieu of appropriate oral data for MEK.

Decreased fetal body weight was also reported in pregnant mice exposed by inhalation to 0, 398, 1010, or 3020 ppm MEK (0, 1174, 2978, or 8906 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15 (Schwetz et al., 1991; Mast et al., 1989). The only maternal effect observed was a concentration-related increase in relative liver and kidney weight. The difference was statistically significant in the dams exposed to 3020 ppm MEK. The biologic significance of this increase has not been ascertained. The decrease in fetal body weight was observed in the 3020-ppm group, however the difference was statistically significant only in the males. There was a statistically significant ($p<0.05$) trend with increasing concentration in the incidence of fetuses with misaligned sternebrae, but this trend was not apparent in the incidence of litters with misaligned sternebrae. Although increased incidence of fetuses and litters with malformations were observed in exposed groups compared with controls, the increases were not statistically significant. The observed fetal malformations (cleft palate, fused ribs, missing vertebrae and syndactyly) present in the exposed groups were not observed in concurrent or contemporary control groups of the same strain of mice. The Schwetz et al. (1991) study identified a NOAEL of 1126 ppm and a LOAEL of 3020 ppm for the occurrence of significant, developmental effects in mice including a decrease in fetal body weight, thereby corroborating the effects observed by Cox et al. (1975).

Sprague-Dawley rats were exposed to 0, 1126, or 2618 ppm MEK (0, 3320, or 7720 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15 (Schwetz et al., 1974). The following endpoints were used to assess exposure-related effects: maternal (body weight, food intake, liver weight, SGOT levels, number of implantations/litter size) and fetal (examination for anomalies, incidence of fetal resorptions, fetal body measurements). No maternal effects or effect on the incidence of fetal resorptions were observed. A decrease in fetal body weight and crown-rump length were observed in the 1126 ppm offspring, however, these effects were not observed in the offspring of the rats exposed to 2618 ppm. There were no gross, soft tissue, or specific skeletal anomalies that occurred at a significantly increased incidence among litters of dams exposed to 1126 ppm MEK. However, the total number of litters containing fetuses with anomalous skeletons was significantly increased compared with controls. In the fetuses of the 2618-ppm group, there was a significantly increased number of fetuses and litters having gross anomalies (two acaudate fetuses with an imperforate anus and 2 brachygnathous fetuses). No single soft tissue anomaly occurred at a statistically significant increased incidence, but the total number of litters containing fetuses with soft tissue anomalies was significantly greater than in controls.

Groups of 25 pregnant Sprague-Dawley rats were exposed to 0, 412, 1002, or 3005 ppm MEK (0, 1215, 2956, or 8861 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15 (Deacon et al., 1981). Decreased maternal body weight gain and increased water consumption were observed in the 3005 ppm group. No other maternal effects were noted. No

statistically significant differences in the incidence of external or soft-tissue alterations were observed among exposed fetuses. A significant decrease in the incidence of delayed ossification of interparietal bones of the skull and an increase in the incidence of extra lumbar ribs and in the occurrence of delayed ossification of cervical centra were noted at the 3005-ppm exposure level.

Data for humans and rats support the assumption that approximately 50% of inhaled MEK is absorbed. From measurements of environmental and exhaled air concentrations, Perbellini et al. (1984) calculated pulmonary retentions of about 70% in workers exposed to concentrations less than 300 ppm for 4 hours (most of the measurements were made at environmental concentrations at or below 100 ppm). From similar measurements, Liira et al. (1988) calculated a pulmonary retention of about 53% for male human volunteers exposed to 200 ppm for 4 hours. Kessler et al. (1988) reported a pulmonary retention of 40% for rats exposed to concentrations less than or equal to 180 ppm for up to about 14 hours.

Although a route-to-route extrapolation could be attempted from the inhalation data, a number of assumptions would need to be made with regard to the inhalation and oral absorption efficiencies making a route-to-route extrapolation limited at best. The developmental effects of MEK inhalation exposure are consistent with the developmental effects seen following oral exposure to 2-butanol and therefore make such an exercise plausible. However, the calculation of an inhalation absorption efficiency for MEK is problematic. The pulmonary retention values discussed above are calculated for exposures of 200 ppm (Liira et al., 1988) and 300 ppm (Perbellini et al., 1984) for a limited 4-hour exposure in humans. The pulmonary retention data of Kessler et al. (1988) using rats, although for a longer period of time (14 hours), was at a maximum concentration of 180 ppm. The calculation of the 40% pulmonary retention value is dependent upon a low concentration that is not limited by metabolic capacity but by transport to the metabolizing enzymes. This retention value, therefore, is valid only if related to normal physiologic processes. Inhalation effects of MEK are seen at concentrations an order of magnitude greater than was used to calculate the rat pulmonary retention value. The toxicity of MEK may be a result of challenges made to a saturable enzymatic detoxification mechanism. Therefore, it cannot be assumed that the pulmonary retention value will be the same at exposures of less than 180 ppm or at greater than 1800 ppm. For this reason, it is inappropriate to estimate the pulmonary retention value at these effect levels, thereby precluding derivation of an oral RfD based upon extrapolation from inhalation effects.

___I.A.5. CONFIDENCE IN THE ORAL RfD

Study -- Low
Data Base -- Low
RfD -- Low

Confidence in the principal study is low. The multigeneration/ developmental study for 2-butanol defined a critical effect that is corroborated by inhalation exposure data. Although the study employed an

adequate number of animals and examined appropriate endpoints, lowering the high-dose group from 3.0 to 2.0% confounded determination of the critical effect. Confidence in the data base is low. This RfD is based on a multigeneration developmental study for a compound that is nearly completely converted to MEK in a short period of time. This compound exhibits similar developmental effects as seen by inhalation exposure to MEK. However, the lack of oral data for MEK itself and the absence of data in a second specie precludes any higher level for data base confidence. This assessment for MEK is based upon the strength of data supporting the use of the 2-butanol multigeneration study and the concurrence of developmental effects for inhalation exposure to MEK and assumes that 2-butanol was not responsible for the fetal toxicity. There is a lack of data on the metabolism of 2-butanol and MEK over time thereby decreasing the confidence in the use of this surrogate approach. Therefore, confidence in the RfD is low.

___I.A.6. EPA DOCUMENTATION AND REVIEW OF THE ORAL RfD

Source Document -- This risk assessment is not presented in any existing U.S. EPA document.

Other EPA Documentation -- U.S. EPA, 1984, 1985

Agency Work Group Review -- 06/24/1985, 07/08/1985, 05/16/1990, 07/17/1991, 09/23/1992,
11/05/1992

Verification Date -- 11/05/1992

___I.A.7. EPA CONTACTS (ORAL RfD)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

__I.B. REFERENCE CONCENTRATION FOR CHRONIC INHALATION EXPOSURE (RfC)

Substance Name -- Methyl ethyl ketone (MEK)

CASRN -- 78-93-3
Last Revised -- 07/01/1992

The inhalation Reference Concentration (RfC) is analogous to the oral RfD and is likewise based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. The inhalation RfC considers toxic effects for both the respiratory system (portal-of-entry) and for effects peripheral to the respiratory system (extrarespiratory effects). It is expressed in units of mg/cu.m. In general, the RfC is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily inhalation exposure of the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Inhalation RfCs were derived according to the Interim Methods for Development of Inhalation Reference Doses (EPA/600/8-88/066F August 1989) and subsequently, according to Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994). RfCs can also be derived for the noncarcinogenic health effects of substances that are carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.B.1. INHALATION RfC SUMMARY

Critical Effect	Exposures*	UF	MF	RfC
Decreased fetal birth weight Mouse Developmental Study Schwetz et al., 1991; Mast et al., 1989	NOAEL: 2978 mg/cu.m (1010 ppm, nominal) NOAEL(ADJ): 2978 mg/cu.m NOAEL(HEC): 2978 mg/cu.m LOAEL: 8906 mg/cu.m (3020 ppm, nominal) LOAEL(ADJ): 8906 mg/cu.m LOAEL(HEC): 8906 mg/cu.m	1000	3	1E+0 mg/cu.m

*Conversion Factors: MW = 72.1 Assuming 25 C and 760 mm Hg. NOAEL (mg/cu.m) = 1010 ppm x 72.1/24.45 = 2978 mg/cu.m. Currently, the approach for dose-response analysis of developmental endpoints does not duration-adjust exposure concentrations. NOAEL(ADJ) = NOAEL = 2978 mg/cu.m. The NOAEL(HEC) was calculated for a gas:extrarespiratory effect assuming periodicity was attained. Since the b:a lambda values are unknown for the experimental animal species (a) and human (h), a default value of 1.0 is used for this ratio. NOAEL(HEC) = NOAEL(ADJ) x (b:a lambda(a)/b:a lambda(h)) = 2978 mg/cu.m.

___I.B.2. PRINCIPAL AND SUPPORTING STUDIES (INHALATION RfC)

Schwetz, B.A., T.J. Mast, R.J. Weigel, J.A. Dill and R.E. Morrissey. 1991. Developmental toxicity of inhaled methyl ethyl ketone in mice. Fund. Appl. Toxicol. 16: 742-748.

Mast, T.J., J.A. Dill, J.J. Evanoff, R.L. Rommereim, R.J. Weigel and R.B. Westerberg. 1989. Inhalation developmental toxicology studies: Teratology study of methyl ethyl ketone in mice. Final Report. Prepared by Pacific Northwest Laboratory, Battelle Memorial Institute, for the National Toxicology Program, Washington, DC. PNL-6833 UC-408.

Pregnant Swiss mice were exposed to 0, 398, 1010 or 3020 ppm methyl ethyl ketone (0, 1174, 2978 or 8906 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15. The Schwetz et al. (1991) and the Mast et al. (1989) reports are the same developmental mouse study presented in different formats and are hence considered as one single study. The number of dams exposed to methyl ethyl ketone ranged from 23-28 mice depending upon exposure group. The dams were killed on gestational day 18. The only maternal effect observed was a concentration-related increase in relative liver and kidney weight. The difference was statistically significant only in the dams exposed to 3020 ppm methyl ethyl ketone. The biological significance of this increase has not been ascertained. A decrease in fetal body weight was also observed in the 3020 ppm exposed group; however, the difference was significant only in the males. There was a significant ($p<0.05$) trend in the incidence of misaligned sternebrae present in fetuses but not reflected in a similar analysis of litters of the animals exposed to 3020 ppm. Additionally, although no significant increase of any single malformation was found, there were several malformations (cleft palate, fused ribs, missing vertebrae and syndactyly) present at low incidences in exposed groups.

Neither maternal nor developmental toxicity was observed at exposures at or less than 1010 ppm (2978 mg/cu.m). At 3020 ppm (8906 mg/cu.m), an equivocal maternal effect was reported; however, mild developmental effects (decreased fetal body weight and misaligned sternebrae) were found. Based on the absence of both maternal and developmental toxic effects, a NOAEL of 1126 ppm (HEC=2978 mg/cu.m) is established. The LOAEL is established at 3020 ppm (HEC=8906 mg/cu.m) based on the appearance of mild, but significant developmental effects.

Groups of 21-23 pregnant Sprague-Dawley rats were exposed to 0, 1126 or 2618 ppm methyl ethyl ketone (0, 3320 or 7720 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15 (Schwetz et al., 1974). The following endpoints were used to assess exposure-related effects: maternal body weight, food intake, liver weight, SGOT levels, and number of implantations/litter size; and fetal anomalies, incidence of resorptions, and fetal body measurements.

No maternal effects or effects on the incidence of fetal resorptions were observed. A decrease in fetal body weight and crown-to-rump length was observed in the offspring exposed to 1126 ppm; however, these effects were not observed in the offspring of the rats exposed to 2618 ppm There were no gross, soft tissue or specific skeletal anomalies that occurred at a significantly increased incidence among litters of dams exposed to 1126 ppm methyl ethyl ketone. However, the total number of litters containing fetuses

with anomalous skeletons was increased significantly compared to controls. In the fetuses exposed to 2618 ppm methyl ethyl ketone, there was a significantly increased number of fetuses and litters having gross anomalies (two acaudate fetuses with an imperforate anus and two brachygnathous fetuses) compared to the incidence among controls. No single soft tissue anomaly occurred at a statistically significant increased incidence, but the total number of litters containing fetuses with soft tissue anomalies was significantly greater than in controls.

The study by Deacon et al. (1981) was conducted to determine the repeatability of the fetotoxic effects observed in the Schwetz et al. (1974) study. Groups of 25 pregnant Sprague-Dawley rats were exposed to 0, 412, 1002 or 3005 ppm methyl ethyl ketone (0, 1215, 2955 or 8861 mg/cu.m, respectively, assuming 25 C and 760 mm Hg) 7 hours/day during gestational days 6-15. Decreased maternal body weight gain and increased water consumption were observed in the group exposed to 3005 ppm. No other maternal effects were noted. No statistically significant differences in the incidence of external or soft-tissue alterations were observed among exposed fetuses. A significant decrease in the incidence of delayed ossification of interparietal bones of the skull and an increase in the incidence of extra lumbar ribs and in the occurrence of delayed ossification of cervical centra were noted at the 3005 ppm exposure level.

___I.B.3. UNCERTAINTY AND MODIFYING FACTORS (INHALATION RfC)

UF -- An uncertainty factor of 1000 reflects factors of 10 to account for interspecies extrapolation, sensitive individuals, and incomplete data base including a lack of chronic and reproductive toxicity studies.

MF -- A modifying factor of 3 was used to address the lack of unequivocal data for respiratory tract (portal-of-entry) effects.

___I.B.4. ADDITIONAL STUDIES/COMMENTS (INHALATION RfC)

Slight nose and throat irritation was observed in 10 human volunteers exposed to 100 ppm methyl ethyl ketone (HEC=295 mg/cu.m) for 5 minutes. Exposure to 300 ppm (HEC=885 mg/cu.m) was judged to be intolerable by the subjects (Nelson et al., 1943).

Male and female volunteers (12-13/sex) were exposed to 186 ppm (HEC=549 mg/cu.m, assuming 25 C and 760 mm Hg) for 4 hours. No statistically significant changes in neurobehavioral performance were observed (Dick et al., 1988).

Groups of male and female Fischer 344 rats (n=15) were exposed to 0, 1254, 2518 or 5041 ppm methyl ethyl ketone (0, 3698, 7425 or 14,865 mg/cu.m,

respectively, assuming 25 C and 760 mm Hg) 6 hours/day, 5 days/week for 90 days (Cavender et al., 1983; Toxigenics, 1981). For each exposure group, 10 animals were used for general histopathology and 5 animals for neuropathologic examination. Tissues examined included nasal cavity, trachea and bronchi, lung, liver and kidney. The prevalence of chronic respiratory disease in the pulmonary region was 100% across control and all exposure groups. There were also high prevalences of nasal inflammation, including submucosal lymphocytic infiltration and lumenal exudate, across control and all exposure groups. These latter lesions, however, varied slightly across the nasal cavity section examined and with exposure level tested. Although the authors suggest that the pulmonary lesions are secondary to mycoplasma infection, no infectious agent was cultured. In other investigations utilizing a model for Mycoplasma pulmonis, pulmonary lesions showed a concentration-response indicative of upper airway irritation (Broderson et al., 1976). The high prevalences of both the nasal and pulmonary lesions in this study preclude unequivocal interpretation regarding respiratory effects. No histopathologic alterations of other major tissues or of neuropathology were observed. An increase in absolute and relative liver weight and relative kidney weight was observed in the animals of both sexes exposed to 5041 ppm. An increase in serum alkaline phosphatase levels was also observed in the female rats exposed to 5041 ppm methyl ethyl ketone. At the highest concentration, females were found to have decreased absolute and increased relative brain weight, however, no pathological changes were observed in the medulla oblongata or the sciatic and tibial nerves. No functional tests (pulmonary or neurologic) were performed in these studies. Based on toxicity remote to the respiratory tract described above, this study provisionally identifies a NOAEL of 2518 ppm (HEC=1326 mg/cu.m) and a LOAEL of 5041 ppm (HEC=2654 mg/cu.m).

Groups of 5 male Wistar rats were exposed to 10,000 ppm methyl ethyl ketone (29,489 mg/cu.m, assuming 25 C and 760 mm Hg) 8 hours/day, 7 days/week for 15 weeks. Because of severe upper respiratory tract irritation, the concentration was lowered to 6000 ppm (17,693 mg/cu.m). The exposed rats died after 7 weeks of exposure; the cause of death was bronchopneumonia. Severe hindlimb weakness was observed in all animals given a methyl ethyl ketone/n-hexane mixture by the 9th week of exposure, which progressed to severe paresis. These effects were observed again when the experiment was repeated. However, these effects were not observed when methyl ethyl ketone was administered alone (Altenkirch et al., 1978).

A group of 25 adult rats (strain not given) was exposed to 235 ppm (693 mg/cu.m) 7 hours/day, 5 days/week for 12 weeks (LaBelle and Brieger, 1955). The dose duration-adjusted concentration is equivalent to 144 mg/cu.m. A control group was included, but the number of animals was not given. At the end of the study, 15 rats were examined microscopically (organs not given) and hematologically (hemoglobin, erythrocyte, leukocyte, neutrophil, lymphocyte, and monocyte counts). The remaining 10 rats were reserved for growth studies. No adverse effects were observed, but only a few critical parameters were measured for a single exposure concentration. Similarly, 15 guinea pigs were exposed to methyl ethyl ketone at the same concentration as were the rats. No adverse effects were reported for the exposed guinea pigs. However, this information is only presented qualitatively in the report. Furthermore, it was reported that the guinea pigs experienced a vitamin deficiency possibly contributing to two deaths during the exposure period.

Male Wistar rats (8/group) were exposed to 0 or 200 ppm methyl ethyl

ketone (0 or 590 mg/cu.m, assuming 25 C and 760 mm Hg) 12 hours/day, 7 days/week for 24 weeks. A slight increase in motor nerve conduction velocity and mixed nerve conduction velocity and a decrease in distal motor latency were observed at 4 weeks of exposure. However, no difference was observed after 4 weeks [NOEL(HEC)=295 mg/cu.m] (Takeuchi et al., 1983).

Groups of 12 Sprague-Dawley rats were continuously exposed to 1125 ppm methyl ethyl ketone (3318 mg/cu.m, assuming 25 C and 760 mm Hg) for 16-55 days. Pathological examination of the sciatic nerve and intrinsic foot muscles revealed no peripheral neuropathy [NOEL(HEC)=3318 mg/cu.m] (Saida et al., 1976).

Four baboons were exposed to 100 ppm methyl ethyl ketone (295 mg/cu.m, assuming 25 C and 760 mm Hg) continuously for 7 days. Operant conditioning behavior conducted during exposure was compared to pre-exposure test scores. The operant behavior selected was a match-to-sample discrimination task and the experimental protocol allowed the performance of each baboon during exposure to be compared to his performances during a clean air exposure in the same chamber immediately prior to each exposure. There was no significant effect on accuracy; however, there was a decrease in mean response time and response during delay (Geller et al., 1979). The authors (Geller et al., 1979) suggested that this could be an early manifestation of the incoordination and narcosis observed in guinea pigs after acute exposure to 10,000 ppm methyl ethyl ketone (29,489 mg/cu.m, assuming 25 C and 760 mm Hg) (Patty et al., 1935). However, it should be pointed out that each baboon in this study was exposed to four different chemicals of which methyl ethyl ketone was given second.

Swiss mice were exposed to various levels of methyl ethyl ketone. A decrease in the immobility developed in a behavioral despair swimming test was observed. A 50% decrease in immobility (ID50) was observed at 2065 ppm (6089 mg/cu.m, assuming 25 C and 760 mm Hg) (DeCeaurriz et al., 1983).

Although the role of methyl ethyl ketone in potentiating peripheral neuropathies caused by potent neurotoxins such as hexane and methyl n-butylketone is documented (Altenkirch et al., 1978; Saida et al., 1976), current experimental data indicate that, by itself, methyl ethyl ketone has little if any neurotoxic potential. Several studies examining neurotoxicity of methyl ethyl ketone have employed neurohistopathology to evaluate toxicity. No peripheral neurohistopathological changes were noted in rats exposed continuously to 1125 ppm methyl ethyl ketone for up to 5 months (Saida et al., 1976). No treatment-related central or peripheral neurohistopathology was observed in rats exposed for 90 days (6 hours/day, 5 days/week) to methyl ethyl ketone concentrations up to 5041 ppm (Toxigenics, 1981; also reported in Cavender et al., 1983). In a study combining experiments of methyl ethyl ketone and n-hexane, Altenkirch et al. (1978) reported that all 10 male rats exposed to 6000 ppm methyl ethyl ketone (8 hours/day, 7 days/week) died in the 7th week without neurological symptoms or pathology although central and extensive peripheral neurohistopathology was observed in animals concurrently exposed to n-hexane. The authors also reported that animals in all exposure groups (both methyl ethyl ketone and hexane) were somnolent during exposure. A few studies have attempted to examine neurological deficits through functional testing in addition to histopathology. Takeuchi et al. (1983) reported an alteration in nerve conduction velocities but only in the 4th week of a 24-week exposure to 200 ppm methyl ethyl ketone; the alteration was not

corroborated by histopathology and was in the opposite direction to that predicted by peripheral neurotoxins such as n-hexane. Results from other functional-deficit studies in humans (Dick et al., 1988) have been negative and in baboons (Geller et al., 1979), inconclusive, perhaps due to experimental design problems. At present, there is no convincing experimental evidence that methyl ethyl ketone, by itself, is neurotoxic to either experimental animals or humans other than possibly inducing CNS depression at high exposure levels.

___I.B.5. CONFIDENCE IN THE INHALATION RfC

Study -- Medium
Data Base -- Low
RfC -- Low

Confidence in the principal study is medium. This and other developmental studies were well-designed and tested several exposure concentrations and several endpoints of toxicity. Although the principal and supporting studies corroborate an effect level for developmental toxicity endpoints, there are insufficient data presented for possible respiratory effects. Confidence in the data base is low. There are no multigenerational studies and only one subchronic study. Furthermore, these studies do not adequately address portal-of-entry effects given that short-term exposure to higher concentrations than that established for the LOAEL cause nasal and throat irritation in both human and experimental animal species. Reflecting medium confidence in the principal study and low confidence in the data base, confidence in the RfC is low.

___I.B.6. EPA DOCUMENTATION AND REVIEW OF THE INHALATION RfC

Source Document -- This is not presented in any existing U.S. EPA document

Other EPA Documentation -- None

Agency Work Group Review -- 04/21/1988, 05/26/1988, 03/22/1990, 05/16/1990, 07/17/1991

Verification Date -- 07/17/1991

___I.B.7. EPA CONTACTS (INHALATION RfC)

Please contact the Risk Information Hotline for all questions concerning this

assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

_II. CARCINOGENICITY ASSESSMENT FOR LIFETIME EXPOSURE

Substance Name -- Methyl ethyl ketone (MEK)
CASRN -- 78-93-3
Last Revised -- 12/01/1989

Section II provides information on three aspects of the carcinogenic assessment for the substance in question; the weight-of-evidence judgment of the likelihood that the substance is a human carcinogen, and quantitative estimates of risk from oral exposure and from inhalation exposure. The quantitative risk estimates are presented in three ways. The slope factor is the result of application of a low-dose extrapolation procedure and is presented as the risk per (mg/kg)/day. The unit risk is the quantitative estimate in terms of either risk per ug/L drinking water or risk per ug/cu.m air breathed. The third form in which risk is presented is a drinking water or air concentration providing cancer risks of 1 in 10,000, 1 in 100,000 or 1 in 1,000,000. The rationale and methods used to develop the carcinogenicity information in IRIS are described in The Risk Assessment Guidelines of 1986 (EPA/600/8-87/045) and in the IRIS Background Document. IRIS summaries developed since the publication of EPA's more recent Proposed Guidelines for Carcinogen Risk Assessment also utilize those Guidelines where indicated (Federal Register 61(79):17960-18011, April 23, 1996). Users are referred to Section I of this IRIS file for information on long-term toxic effects other than carcinogenicity.

__II.A. EVIDENCE FOR CLASSIFICATION AS TO HUMAN CARCINOGENICITY

___II.A.1. WEIGHT-OF-EVIDENCE CLASSIFICATION

Classification -- D; not classifiable as to human carcinogenicity

Basis -- Based on no human carcinogenicity data and inadequate animal data.

II.A.2. HUMAN CARCINOGENICITY DATA

None.

II.A.3. ANIMAL CARCINOGENICITY DATA

Inadequate. No data were available to assess the carcinogenic potential of methyl ethyl ketone by the oral or inhalation routes. In a skin carcinogenesis study, two groups of 10 male C3H/He mice received dermal applications of 50 mg of a solution containing 25 or 29% methyl ethyl ketone in 70% dodecylbenzene twice a week for 1 year. No skin tumors developed in the group of mice treated with 25% methyl ethyl ketone. After 27 weeks, a single skin tumor developed in 1 of 10 mice receiving 29% methyl ethyl ketone (Horton et al., 1965).

II.A.4. SUPPORTING DATA FOR CARCINOGENICITY

Methyl ethyl ketone was not mutagenic for Salmonella typhimurium strains TA98, TA100, TA1535, or TA1537 with or without rat hepatic homogenates (Florin et al., 1980; Douglas et al., 1980). Methyl ethyl ketone induced aneuploidy in the diploid D61, M strain of Saccharomyces cerevisiae (Zimmermann et al., 1985). Low levels of methyl ethyl ketone combined with low levels of nocodazole (another inducer of aneuploidy), also produced significantly elevated levels of aneuploidy in the system (Mayer and Goin, 1987).

II.B. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM ORAL EXPOSURE

None.

II.C. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM INHALATION EXPOSURE

None.

__II.D. EPA DOCUMENTATION, REVIEW, AND CONTACTS (CARCINOGENICITY ASSESSMENT)

___II.D.1. EPA DOCUMENTATION

U.S. EPA. 1985. Health and Environmental Effects Profile for Methyl Ethyl Ketone. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Solid Waste and Emergency Response, Washington, DC.

U.S. EPA. 1988. Updated Health Effects Assessment for Methyl Ethyl Ketone. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Solid Waste and Emergency Response, Washington, DC.

The 1988 Updated Health Effects Assessment for Methyl Ethyl Ketone has received Agency review.

___II.D.2. REVIEW (CARCINOGENICITY ASSESSMENT)

Agency Work Group Review -- 05/30/1989

Verification Date -- 05/30/1989

___II.D.3. U.S. EPA CONTACTS (CARCINOGENICITY ASSESSMENT)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

OPPT Chemical Fact Sheet EPA 749-F-94-015

CHEMICALS IN THE ENVIRONMENT: METHYL ETHYL KETONE (CAS NO. 78-93-3)

prepared by
OFFICE OF POLLUTION PREVENTION AND TOXICS
U.S. ENVIRONMENTAL PROTECTION AGENCY
September 1994

Chemicals can be released to the environment as a result of their manufacture, processing, and use. EPA has developed information summaries on selected chemicals to describe how you might be exposed to these chemicals, how exposure to them might affect you and the environment, what happens to them in the environment, who regulates them, and whom to contact for additional information. EPA is committed to reducing environmental releases of chemicals through source reduction and other practices that reduce creation of pollutants.

WHAT IS METHYL ETHYL KETONE, HOW IS IT USED, AND HOW MIGHT I BE EXPOSED?

Methyl ethyl ketone (also called MEK and 2-butanone) is a colorless, flammable liquid. It occurs naturally in certain foods and beverages. It is produced in large amounts (estimated to be 500 million pounds in 1992) by three companies in the United States. US demand for MEK is likely to decrease gradually until makers of protective surface coatings begin using other substances. Once companies make this change, US demand for MEK is likely to fall more rapidly. The largest users of MEK are companies that add it to protective surface coatings. Other companies add MEK to adhesives, printing inks, paint removers, and special lubricating oils. Companies also use MEK to make other chemicals, including those used as drugs and cosmetics. Small amounts of MEK are used to sterilize surgical instruments, hypodermic needles, syringes, and dental instruments. It is also used to extract vegetable oil.

Exposure to MEK can occur in the workplace or in the environment following releases to air, water, land, or groundwater. Exposure can also occur when people use certain paints, paint removers, or adhesives. Methyl ethyl ketone enters the body when breathed in with contaminated air or when consumed with contaminated food or water. It can also be absorbed through skin contact. It is not likely to remain in the body due to its breakdown and removal in expired air and in urine.

WHAT HAPPENS TO METHYL ETHYL KETONE IN THE ENVIRONMENT?

Methyl ethyl ketone evaporates when exposed to air. It dissolves when mixed with water. Most direct releases of MEK to the environment are to air. It can also evaporate from water and soil exposed to air. Once in air, it is expected to break down to other chemicals. Microorganisms that live in water and in soil can also break down MEK. Because it is a liquid that does not bind well to soil, MEK that makes its way into ground can move through the ground and enter groundwater. Plants and animals are not likely to store methyl ethyl ketone.

HOW DOES METHYL ETHYL KETONE AFFECT HUMAN HEALTH AND THE ENVIRONMENT?

Effects of methyl ethyl ketone on human health and the environment depend on how much MEK is present and the length and frequency of

exposure. Effects also depend on the health of a person or the condition of the environment when exposure occurs.

Breathing MEK for short periods of time, such as when painting in a poorly vented area, can adversely affect the nervous system. Effects range from headaches, dizziness, nausea, and numbness in fingers and toes to unconsciousness. MEK vapor irritates the eyes, the nose, and the throat. Direct, prolonged contact with liquid methyl ethyl ketone irritates the skin and damages the eyes. These effects are not expected to occur at levels of MEK that are normally found in the environment.

Human health effects associated with breathing or otherwise consuming smaller amounts of methyl ethyl ketone over long periods of time are not known. Workers have developed dermatitis, upset stomachs, loss of appetite, headaches, dizziness, and weakness as a result of repeated exposure to MEK. Laboratory studies show that exposure to large amounts of MEK in air causes animals to give birth to smaller offspring. Studies also show that repeat exposure to large amounts of MEK in air causes adverse liver and kidney effects in animals.

Methyl ethyl ketone by itself is not likely to cause environmental harm at levels normally found in the environment. MEK can contribute to the formation of photochemical smog when it reacts with other volatile organic carbon substances in air.

WHAT EPA PROGRAM OFFICES REGULATE METHYL ETHYL KETONE, AND UNDER WHAT LAWS IS IT REGULATED?

EPA OFFICE	LAW	PHONE NUMBER
Pollution Prevention & Toxics	Toxic Substances Control Act	(202) 554-1404
	Emergency Planning and Community Right-to-Know Act (EPCRA) Regulations (Sec. 313)	(800) 535-0202

CHEMICAL SUMMARY FOR METHYL ETHYL KETONE

prepared by
OFFICE OF POLLUTION PREVENTION AND TOXICS
U.S. ENVIRONMENTAL PROTECTION AGENCY
September 1994

This summary is based on information retrieved from a systematic search limited to secondary sources (see Appendix A). These sources include online databases, unpublished EPA information, government publications, review documents, and standard reference materials. No attempt has been made to verify information in these databases and secondary sources.

I. CHEMICAL IDENTITY AND PHYSICAL/CHEMICAL PROPERTIES

The chemical identity and physical/chemical properties of methyl ethyl ketone are summarized in Table 1.

TABLE 1. CHEMICAL IDENTITY AND CHEMICAL/PHYSICAL PROPERTIES OF METHYL ETHYL KETONE

Characteristic/Property	Data	Reference
CAS No.	78-93-3	
Common Synonyms	2-Butanone, MEK	Verschueren 1983
Molecular Formula	C4H80	
Chemical Structure	O || CH3-C-CH2-CH3	
Physical State	liquid	Budavari 1989
Molecular Weight	72.10	Budavari 1989
Melting Point	-86øC	Budavari 1989
Boiling Point	79.6øC	Budavari 1989
Water Solubility	353 g/L @ 10øC; 190 g/L @ 90øC	Verschueren 1983
Specific gravity	0.805 @ 20/4øC	Verschueren 1983
Vapor Density (air = 1)	2.41	Verschueren 1983
KOC	4.5 -50 (estimated)	U.S. EPA 1989
Log KOW	0.29 (estimated)	U.S. EPA 1989
Vapor Pressure	77.5 mm Hg @ 20øC 98.0 mm Hg @ 25øC	Verschueren 1983 U.S. EPA 1985
Reactivity	Liquid and vapor are flammable.	U.S. Air Force 1989
Flash Point	-6øC (closed cup)	Budavari 1989
Henry's Law Constant	4.16 to 6.11 X 10-5 atm-m3/mol @ 25øC (estimated)	U.S. EPA 1985
Fish Bioconcentration Factor	<1 (estimated)	U.S. EPA 1985
Odor Threshold	5 to 10 ppm (in air)	U.S. Air Force 1989
Conversion Factors	1 ppm = 2.94 mg/m3 1 mg/m3 = 0.34 ppm	Verschueren 1983

II. PRODUCTION, USE, AND TRENDS

A. Production

There are three methyl ethyl ketone producers in the United States. Table 2 lists producers, plant locations, and plant capacities. Annual US capacity is approximately 545 million pounds. In 1992, an estimated 494 million pounds of methyl ethyl ketone were produced in the US. During that same year, 55 million pounds were imported into the US and 112 million pounds were exported (Mannsville 1993).

B. Use

Methyl ethyl ketone is used in a number of industrial applications.

The primary use of methyl ethyl ketone, accounting for approximately 63 percent of all use, is as a solvent in protective coatings. It is also used as a solvent in adhesives; printing inks; paint removers; in the production of magnetic tapes; and in dewaxing lubricating oil. Methyl ethyl ketone is used as a chemical intermediate in several reactions, including condensation; halogenation; ammonolysis; and oxidation. Small amounts of methyl ethyl ketone are also used as a sterilizer for surgical instruments, hypodermic needles, syringes, and dental instruments; as an extraction solvent for hardwood pulping and vegetable oil; and as a solvent in pharmaceutical and cosmetic production (Mannsville 1993; HSDB 1994). Table 3 shows the estimated 1992 US end-use pattern for methyl ethyl ketone.

C. Trends

Demand for methyl ethyl ketone is expected to decrease gradually until alternative, low volatile organic carbon (VOC) coating technologies are readily available (Mannsville 1993). Once such alternatives are available, demand is expected to decrease more rapidly.

TABLE 2. United States Producers of Methyl Ethyl Ketone

Company	Plant Location	Plant Capacity (in millions of pounds)
Exxon Chemical	Baton Rouge, LA	230
Hoechst Celanese	Pampa, TX	85
Shell Chemical	Norco, LA	230

Source: Mannsville 1993.

TABLE 3. Estimated 1992 United States End-Use Pattern of Methyl Ethyl Keton

Use of Methyl Ethyl Ketone (typical Standard Industrial Classification (SIC) Code) (see end note 1)	Percentage of US Methyl Ethyl Ketone Use
Protective coatings solvent	

(production, SIC 2851)	63%
Adhesives solvent (production, SIC 2891)	13%
Magnetic tapes (production, SIC 3652, 3695)	10%
Lubricating oil dewaxing (production, SIC 2992)	5%
Chemical intermediate (production, SIC 2865, 2869)	4%
Printing inks (production, SIC 2893)	3%
Miscellaneous (no applicable SIC Code(s))	2%

Source: Mannsville 1993.

III. ENVIRONMENTAL FATE

A. Environmental Release

Of the total methyl ethyl ketone released to the environment almost all eventually enters the air. Methyl ethyl ketone is released into the environment from industrial and domestic uses. The largest man made sources of methyl ethyl ketone release are from its primary use as a solvent for coatings, resins, and adhesives (U.S. EPA 1985). Methyl ethyl ketone has been found in cigarette smoke (500 ppm) and in gasoline engine exhaust (<0.1-1.0 ppm) (Verschueren 1983). Its use as a solvent in polyvinyl chloride pipe joint cement has introduced the chemical into drinking water (4.5 ppm, 6 months after installation) (HSDB 1994). It occurs naturally and has been found in a number of foods and beverages including swiss cheese (0.3 ppm), cream (0.154-0.177 ppm), barley, bread, honey, oranges, black tea, rum, non-alcoholic beverages (70 ppm), and ice cream (270 ppm) (HSDB 1994).

In 1992, releases of methyl ethyl ketone to environmental media, as reported to the Toxic Chemical Release Inventory by certain types of US industries totaled about 91.3 million pounds. Of this amount, a total of 90.5 million pounds (99%) was released to the atmosphere, 153 thousand pounds were released to surface water, 365 thousand pounds to underground injection, and 242 thousand pounds were released to land (TRI92 1994).

Although the atmospheric concentration of methyl ethyl ketone increases during episodes of severe photochemical smog (up to 14 ppb in Los Angeles, CA during a photochemical pollution episode), ambient concentrations are usually below the detection limit (0.01 ppb) in most urban areas. Air levels averaging 64 ppb have been measured near industrial sources of the chemical, and a concentration of 94 ppm has been measured in the vicinity of a chemical reclamation plant (HSDB 1994). Methyl ethyl ketone was detected in less than 5% of groundwater samples in a federal survey of drinking water supplies, and in only one (found at a level of 23 ppb) of 204 sites from 14 heavily industrialized river basins in the United States. The chemical has been detected in clouds, fog, and ice fog in California (trace-0.47 ppm in positive samples), but not detected in rain. It was found in rain in Japan. It was also detected in the trench leachate from two low-level radioactive disposal sites (HSDB 1994).

B. Transport

Methyl ethyl ketone is not expected to be retarded by adsorption to soils rich in organic material [estimated Koc = 4.5-50 (U.S. EPA 1989)]; therefore, it is expected to be mobile in soil and,

subject to leaching from landfills. The relatively high vapor pressure [98.0 mm Hg @ 25øC (U.S. EPA 1985)] and estimated Henry's Law constant (4.16-6.11 x 10-5 atm m3/mol @ 25øC) indicate that it can volatilize from moist and dry soil (HSDB 1994). It does not adsorb significantly to suspended solids, and will volatilize to the atmosphere from surface waters (HSDB 1994; U.S. EPA 1985).

C. Transformation/Persistence

1. Air - The main degradation pathway for methyl ethyl ketone in the atmosphere is reaction with photochemically produced hydroxyl radicals, primarily producing acetaldehyde. The half-life of methyl ethyl ketone from the reaction with hydroxyl radicals has been estimated to be about 2.3 days (HSDB 1994). Direct photolysis with a calculated half-life of about 15.4 hours at a solar zenith angle of 30ø is expected to occur (U.S. EPA 1985). Deposition by rain or fog may play a minor role in transporting methyl ethyl ketone from the atmosphere. It has also been shown to be reactive in smog chamber studies (U.S. EPA 1985).

2. Soil - In wet or dry soil, methyl ethyl ketone will volatilize to air and may undergo photolysis on the soil surface (U.S. EPA 1985). It is also highly mobile and may be leached from the soil by water, and has been shown to be degradated by cultures of soil bacteria (U.S. EPA 1985).

3. Water - The most important fate process for methyl ethyl ketone in water is volatilization (estimated half-times of 3 and 12 days, for rivers and lakes, respectively). Complete aerobic biodegradation of methyl ethyl ketone has been reported in about 5-10 days following inoculation with sewage or polluted surface water. Longer times were required for degradation in marine water. Anaerobic degradation occurred after an acclimation period of about one week (HSDB 1994). Direct photolysis near the surface is also thought to be a possible mechanism, but was not measured (HSDB 1994). It is not expected to undergo chemical hydrolysis or to be bound to sediment or suspended organic matter (HSDB 1994).

4. Biota - Methyl ethyl ketone is not expected to bioconcentrate in fish or aquatic organisms; its estimated fish bioconcentration factor is less than 1 (U.S. EPA 1985).

IV. HUMAN HEALTH EFFECTS

A. Pharmacokinetics

1. Absorption - Studies in humans and animals have demonstrated that methyl ethyl ketone can be absorbed via the lungs, the skin, and the gastrointestinal system. The concentration of methyl ethyl ketone in the atmosphere has been correlated with the alveolar concentration (70% alveolar retention) and blood levels in humans (U.S. EPA 1985). Pulmonary absorption values range from 41.1% to 55.8% (WHO 1993). The relative uptake through the lungs by humans was about 53% through a 4 hour exposure at 200 ppm (HSDB 1994; WHO 1993). Oral studies in rats have demonstrated that the peak blood level of methyl ethyl ketone (0.95 mg/mL) was reached in 4 hours following oral

administration of the chemical in water (1690 mg/kg) (U.S. EPA 1985). Methyl ethyl ketone can also be absorbed through intact human skin. A steady state concentration in expired air was reached in 2-3 hours following exposure of the palmar surface of the forearm of volunteers (Krasavage et al. 1982). Absorption is more rapid through moist skin than through dry skin, and the rate of percutaneous absorption has been estimated to range from 5 to 10 micrograms/cm2/min (WHO 1993).

2. Distribution - The relative solubility of methyl ethyl ketone in various human tissues and organs compared to blood (tissue/blood partition coefficient) was shown to be similar in the kidney, liver, brain, heart, and lung and in fat and muscle tissue. This indicates a potential for even and widespread distribution of methyl ethyl ketone in human tissues (U.S. EPA 1985). It has also been shown to cross the placenta and enter the human fetus (WHO 1993).

3. Metabolism - Experiments with guinea pigs and rats have shown that methyl ethyl ketone is metabolized by oxidative hydroxylation, forming 3-hydroxy-2-butanone, which is further reduced to 2,3-butanediol. Methyl ethyl ketone is also reversibly reduced to 2-butanol (U.S. EPA 1985).

4. Excretion - The half-life of methyl ethyl ketone in the blood of guinea pigs was reported to be 270 minutes, following intraperitoneal injection of 450 mg/kg. The clearance time was 12 hours (U.S. EPA 1985). It has been estimated that humans eliminate 30 to 40% of methyl ethyl ketone intake in expired air (HSDB 1994). The unchanged chemical and its metabolite, 3-hydroxy-2-butanone were measured in the urine of workers occupationally exposed to 8 to 272 mg/m3. The metabolite was only identified in workers exposed to the higher levels, and was correlated with the level of exposure and the urinary concentration of methyl ethyl ketone (U.S. EPA 1985). The plasma half-time in humans has be estimated at 49-96 minutes with an apparent clearance rate of 0.6 L/minute (ATSDR 1992).

B. Acute Toxicity

Acute exposure to moderate to high doses of methyl ethyl ketone can cause headaches, nausea, and irritation of the eyes and respiratory tract; high doses can also result in narcosis. Eye contact with liquid methyl ethyl ketone can cause corneal injury.

1. Humans - Volunteers complained of mild nose and throat irritation when exposed to 100 ppm. The irritation became objectionable when the concentration was raised to 300 ppm (ATSDR 1992). Workers occupationally exposure to an atmosphere containing 300 to 500 ppm (126 to 210 mg/kg/day) (see end note 2) complained of headaches, nausea, and respiratory tract irritation. Momentary exposure to 33,000 or 100,000 ppm caused intolerable irritation of the eyes, nose and throat (Krasavage et al. 1982). Workers exposed either by inhalation (300-600 ppm) or by skin contact to methyl ethyl ketone developed numbness in the extremities and dermatitis. High concentrations can result in central nervous system depression (see Section IV.G.1.). Eye contact with liquid methyl ethyl ketone causes painful irritation, and can result in corneal injury (Krasavage et al. 1982; HSDB 1994).

2. Animals - Oral LD50 values of 2737 and 4050 mg/kg were reported for rats and mice, respectively. Inhalation LC50 values of 23,500 mg/m3/8 hours for rats and 40,000 mg/m3/2 hours for mice were reported (U.S. EPA 1985). Guinea pigs exposed to 10,000 ppm methyl ethyl ketone developed liver and kidney congestion, but no effects were seen at 3500 ppm (ATSDR 1992).

C. Subchronic/Chronic Effects

Human studies have indicated that extended or repeated exposure to relatively high concentrations of methyl ethyl ketone can result in adverse central nervous system effects. Animal studies indicate that extended or repeated inhalation exposure to relatively high concentrations of methyl ethyl ketone can result in hepatic and renal toxicity.

1. Humans - Dermatitis, gastrointestinal upset, loss of appetite and weight, and neurological problems (see Section IV.G.1.) were reported by individuals occupationally exposed to methyl ethyl ketone, apparently in the absence of other solvents (WHO 1993). Neurological problems were also reported by workers chronically exposed to 300-600 ppm of the chemical (WHO 1993). All other available studies describing subchronic/chronic occupational exposure involved a mixture of organic solvents that contained methyl ethyl ketone. A variety of nervous system effects were consistently described after prolonged exposure to these mixtures (see Section IV.G.1.) (WHO 1993).

2. Animals - Male and female Fischer 344 rats were exposed to 0, 1250, 2500, or 5000 ppm methyl ethyl ketone by inhalation 6 hours/day, 5 days/week, for 90 days. No treatment related differences in food consumption, in eye effects, in neurological functioning, or in histopathologies were reported (U.S. EPA 1985). Increased serum alanine amino transferase in females was the only effect at 2500 ppm; increased absolute and relative liver weight were seen in both sexes at 5000 ppm. Females also developed decreased relative brain weight, and increased blood levels of alkaline phosphatase, glucose, and potassium at 5000 ppm. The mean body weights of both sexes were decreased at 5000 ppm, but increased at the other dose levels compared to the controls.

   In another inhalation study Fischer 344 rats were exposed by inhalation to 5041 ppm (14,870 mg/m3), 2518 ppm, or 1254 ppm methyl ethyl ketone for 6 hours/ day, 5 days/week for 90 days. No significant effects on food consumption, eyes, or morphology were observed (WHO 1993). Increased absolute and relative liver weight, decreased body weight, increased relative kidney weight, decreased relative brain and spleen weights, and increased mean corpuscular hemoglobin were reported at the high dose. Increased body weights were reported at the low and intermediate dose.

   Male rats exposed to 10,000 ppm methyl ethyl ketone 8 hours/day, 7 days/week developed severe irritation in the upper respiratory tract within a few days and died during the 7th week of exposure of bronchopneumonia (ATSDR 1992).

D. Carcinogenicity

There is inadequate information to evaluate the carcinogenicity of

methyl ethyl ketone in humans and in laboratory animals.

1. Humans - No excess cancer incidence was found in an epidemiological study of 446 male workers in two methyl ethyl ketone dewaxing plants. The deaths observed were below the expected, and overall deaths from cancer were also below the expected. An increase in tumors of the buccal cavity and pharynx was seen but the numbers were small (2 observed, 0.13 expected) and lung cancers were significantly decreased (1 observed, 6.02 expected) (ATSDR 1992; WHO 1993). The overall cancer-related mortality was less than expected in another epidemiological study of 1008 male oil refinery workers exposed to 1-4 ppm methyl ethyl ketone. There were no increases in buccal and pharyngeal cancers seen in this study (ATSDR 1992).

2. Animals - Methyl ethyl ketone was applied to the skin of mice twice weekly for one year (50 mg/dose). No tumors were reported (U.S. EPA 1989). No information on the carcinogenicity of methyl ethyl ketone by other routes of administration were found in the secondary sources searched.

E. Genotoxicity

Results from four out of the five short term mutagenicity assays, requested by and submitted to EPA under the Toxic Substances Control Act (TSCA), indicate methyl ethyl ketone is not mutagenic. Methyl ethyl ketone is negative in the Ames test (in Salmonella typhimurium strains TA98, TA100, TA1535, and TA1537 with or without S-9 metabolic activation); the mouse lymphoma test; the cell transformation assay; and the mouse micronucleus test. Results from the Section 4 unscheduled DNA test was concluded to be positive (Cimino 1985).

Most of the information from other secondary sources also indicate that methyl ethyl ketone is not genotoxic. Methyl ethyl ketone was negative in E. coli tester strains WP2 and WP2uvrA (WHO 1993). It was negative in the mitotic gene conversion assay in S. cerevisiae tester strain JD1 (WHO 1993). It was negative in the micronucleus test in both CD1 mice and Chinese hamsters (WHO 1993). It was a strong inducer of aneuploidy in S. cerevisiae strain D61.M (U.S. EPA 1989).

F. Developmental/Reproductive Toxicity

Animal studies indicate that exposure to high methyl ethyl ketone concentrations in air breathed during pregnancy can cause fetal toxicity and possibly adverse developmental effects. EPA has derived an oral reference dose (RfD) (see end note 3) of 0.6 mg/kg/day, based on developmental effects of a metabolite (2-butanol) of MEK. EPA has derived an inhalation reference concentration (RfC) (see end note 4) of 1 mg/m3 for methyl ethyl ketone, based on its developmental effects.

1. Humans - No information on the developmental/reproductive toxicity of methyl ethyl ketone was found in the secondary sources searched.

2. Animals - Since there are no appropriate oral studies on methyl ethyl ketone, the U.S. EPA (1994) calculated a chronic oral RfD for methyl ethyl ketone of 0.6 mg/kg/day, based on decreased birth weights seen in a multigeneration study with its metabolic intermediate, 2-butanol. Male and female Wistar rats (30/sex/

group) were given 2-butanol in drinking water at 0, 0.3, 1.0, or 3.0% nine weeks before mating through gestation and lactation. The high dose was reduced to 2.0% for the second generation. Decreased fetal weight and decreased pup survivability were reported for the first generation at 3.0% 2-butanol. Decreased fetal weight was seen in the second generation at 2.0%. Increases in the incidences of missing sternebrae, wavy ribs, and incomplete vertebrae ossification at 2%, compared to the 1.0 and 0.3% groups, were seen. However, because of high incidences of these developmental effects in the control group, they could not be determined to be treatment related. The 1.0% dose, equivalent to 1771 mg/kg/day, was identified as a no-adverse-effect-level (NOAEL), and the 2.0% dose was identified as a lowest-adverse-effect-level (LOAEL) (U.S. EPA 1994).

The U.S. EPA (1994) calculated a chronic inhalation reference concentration (RfC) of 1.0 mg/m3 for methyl ethyl ketone, based on decreased fetal birth weight seen in a mouse inhalation study. Pregnant mice were exposed by inhalation to atmospheric concentrations of 0, 398, 1010, or 3020 ppm methyl ethyl ketone 7 hours/day during days 6-15 of gestation. Decreased fetal body weight was seen at 3020 ppm. There was an increased incidence of fetuses and litters with malformations in the treated groups, but the increases were not statistically significant. A NOAEL of 1010 ppm and a LOAEL of 3020 ppm were identified (U.S. EPA 1994).

Groups of 25 pregnant Sprague-Dawley rats were exposed to air concentrations of 400, 1000, or 3000 ppm methyl ethyl ketone 7 hours/day during days 6-15 of gestation. The control group contained 35 rats. Maternal body weight gain was decreased and water consumption was increased in dams receiving 3000 ppm. There were no treatment related effects on the pregnancy rate, the number of implantations per litter, or the percent live fetuses. A total of five fetuses with at least one external or soft tissue malformation were reported, but were distributed in all groups including the control. Increased incidences of delayed ossification and extra ribs at the 3000 ppm dose were attributed to fetal toxicity (U.S. EPA 1989).

G. Neurotoxicity

Neurological effects, observed in humans and animals exposed to high concentrations of methyl ethyl ketone, appear to be reversible. Concentrations high enough to cause central nervous system depression also cause severe pulmonary irritation.

1. Humans - American workers exposed to 300-600 ppm methyl ethyl ketone reported numbness in the fingers and toes. Italian workers chronically exposed to the chemical developed reduced nerve conduction velocities, headaches, dizziness, and muscle hypotrophy (WHO 1993).

   Most reports involving human exposure to methyl ethyl ketone describe effects seen after exposure to mixtures of solvents. Methyl ethyl ketone has been shown to potentiate the effects of other solvents, especially n-hexane (U.S. EPA 1989). Workers exposed to a mixture containing methyl ethyl ketone (39 ppm), n-hexane (90 ppm), cyclohexane (92 ppm), and ethyl acetate (57 ppm) complained of sleepiness, dizziness weakness, paraesthesia, and hypo-aesthesia (WHO 1993). Reductions in the maximal motor and distal sensory nerve conduction velocities in

the median and ulnar nerves and decreased maximal motor nerve conduction velocity in the peroneal nerve were reported after 2-8 years exposure to a mixture containing methyl ethyl ketone (60 ppm), n-hexane (196 ppm), cyclohexane (170 ppm) and ethyl acetate (100 ppm). The latency of sensory peak action potentials were increased and the amplitude of peripheral nerve action potentials were decreased. The effects were attributed to n-hexane, possibly potentiated by methyl ethyl ketone (WHO 1993).

2. Animals - Wistar rats exposed to 200 ppm (roughly equivalent to 244 mg/kg/dy) methyl ethyl ketone 12 hours/day, 7 days/week, for 24 weeks exhibited transient increases in motor nerve conduction velocities and decreased distal motor latency. These effects were observed after four weeks of exposure but not after 12 weeks (U.S. EPA 1989). Transient behavioral changes were reported in baboons exposed to 100 ppm for 7 days. Intravenous infusion of 5 mg/kg methyl ethyl ketone per hour into Sprague-Dawley rats resulted in depression of the vestibulo-oculomotor reflex. Depression of the central nervous system followed with continued infusion (WHO 1993). No neuropathology or histological changes were found in several experiments in chickens, cats, rats, and mice exposed to atmospheres containing up to 1500 ppm for up to 12 weeks. Exposure to high concentrations results in narcosis.

Guinea pigs exposed to an atmospheric concentration of 10,000 ppm experience narcosis in four to five hours; however, irritation of the eyes and nose develops within four minutes (Krasavage et al. 1982).

V. ENVIRONMENTAL EFFECTS

The toxicity of methyl ethyl ketone in aquatic organisms is low; toxicity values are greater than 100 mg/L. It also has low toxicity in terrestrial rodents for inhalation exposure.

A. Toxicity to Aquatic Organisms

24 Hour LC50 values for fish are: >5000 mg/L for Carassius auratus (goldfish); >400 mg/L for Cyprinodon variegatus (sheepshead minnow); and 5640 mg/L for Lepomis macrochirus (bluegill) (AQUIRE 1994). 96 Hours LC50 values for fish include: 3200 mg/L for Pimephales promelas (fathead minnow); 5600 mg/L for Gambusia affinis (mosquito fish); and 4467 mg/L for Lepomis macrochirus (bluegill) (WHO 1993). 24 Hour LC50 values of 8890 mg/L for Daphnia magna (water flea) and 1950 mg/L for Artemia salina (brine shrimp) were reported (WHO 1993).

B. Toxicity to Terrestrial Organisms

The toxicity information reported for rats and rabbits (see sections IV.B.2. and IV.C.2.) suggests that no adverse effects would be seen at expected environmental concentrations.

C. Abiotic Effects

Methyl ethyl ketone is known to contribute to photochemical smog episodes (Federal Register 1992). Smog chamber studies indicate that methyl ethyl ketone is of intermediate reactivity with degradation rates ranging from 1.5% in one hour to 33% in 6.5 hour (HSDB 1994).

VI. EPA/OTHER FEDERAL ACTIVITY

Voluntary reduction of methyl ethyl ketone environmental releases has occurred since 1991, as a result of a joint industry/EPA pollution prevention initiative known as the 33/50 program. The 1990 Clean Air Act Amendments list methyl ethyl ketone as a hazardous air pollutant. Occupational exposure to methyl ethyl ketone is regulated by the Occupational Safety and Health Administration (OSHA). The permissible exposure limit (PEL) is 200 parts per million parts of air (ppm) as an 8-hour time-weighted average (TWA) (29 CFR 1910.1000) (Mannsville 1993).

Federal agencies/other groups that can provide additional information on methyl ethyl ketone are listed in Table 4 and 5.

TABLE 4. EPA OFFICES AND CONTACT NUMBERS FOR INFORMATION ON METHYL ETHYL KETONE

Occupational Safety & Health Administration Permissible TWA: 200 ppm (see end note 6) (OSHA 1993)	Check local phone book for phone number under Department of Labor

VII. END NOTES

1. Standard Industrial Classification code is the statistical classification standard for all Federal economic statistics. The code provides a convenient way to reference economic data on industries of interest to the researcher. SIC codes presented here are not intended to be an exhaustive listing; rather, the codes listed should provide an indication of where a chemical may be most likely to be found in commerce.

2. Calculated using the factor, 2.94 (Verschueren 1983), to convert ppm to mg/m3, which is multiplied by 0.1429 (the occupational 8-hour breathing rate, 10 m3, divided by the assumed adult body weight, 70 kg) to obtain the dose in mg/kg/day assuming 100% absorption (U.S. EPA 1988).

3. The RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of the daily exposure level for the human population, including sensitive subpopulations, that is likely to be without an appreciable risk of deleterious effects during the time period of concern.

4. An inhalation reference concentration is an estimate (with uncertainty spanning perhaps an order of magnitude) of the exposure level for the human population, including sensitive populations, that is likely to be without an appreciable risk of deleterious effects during the time period of concern.

5. TWA, occupational, Time Weighted Average; STEL, occupational, Short Term Exposure Limit, 15 min.; IDLH, Immediate Danger to Life and Health.

6. PEL-TWA, Permissible Exposure Limit-Time Weighted Average

7. TLV-TWA, Threshold Limit Value-Time Weighted Average; TLV-STEL, Threshold Limit Value-Short Term Exposure Limit

ICSC # 0179
UN # 1193
EC # 606-002-00-3

TYPES OF HAZARD/ EXPOSURE	ACUTE HAZARDS/ SYMPTOMS	PREVENTION	FIRST AID/ FIRE FIGHTING
FIRE	Highly flammable.	NO open flames, NO sparks, and NO smoking.	Powder, AFFF, foam, carbon dioxide.
EXPLOSION	Vapour/air mixtures are explosive.	Closed system, ventilation, explosion-proof electrical equipment and lighting. Do NOT use compressed air for filling, discharging, or handling. Use non-sparking handtools.	In case of fire: keep drums, etc., cool by spraying with water.
EXPOSURE			
• **INHALATION**	Cough. Dizziness. Drowsiness. Headache. Nausea. Vomiting.	Ventilation, local exhaust, or breathing protection.	Fresh air, rest. Refer for medical attention.
• **SKIN**		Protective gloves.	Remove contaminated clothes. Rinse skin with plenty of water or shower.
• **EYES**	Redness. Pain.	Safety goggles.	First rinse with plenty of water for several minutes (remove contact lenses if easily possible), then take to a doctor.

• **INGESTION**	Unconsciousness. (Further see Inhalation).	Do not eat, drink, or smoke during work.	Rinse mouth. Give plenty of water to drink. Refer for medical attention.

SPILLAGE DISPOSAL	STORAGE	PACKAGING & LABELLING
Collect leaking and spilled liquid in sealable containers as far as possible. Absorb remaining liquid in sand or inert absorbent and remove to safe place. Do NOT wash away into sewer. (extra personal protection: self-contained breathing apparatus).	Fireproof. Separated from strong oxidants, strong acids. Cool. Well closed. International Chemical Safety Cards

METHYL ETHYL KETONE

ICSC: 0179

IMPORTANT DATA

PHYSICAL STATE; APPEARANCE:
COLOURLESS LIQUID , WITH CHARACTERISTIC ODOUR.

PHYSICAL DANGERS:
The vapour is heavier than air and may travel along the ground; distant ignition possible.

CHEMICAL DANGERS:
Reacts violently with strong oxidants and inorganic acids, causing fire and explosion hazard. Attacks some plastics.

OCCUPATIONAL EXPOSURE LIMITS (OELs):
TLV (as TWA): 200 ppm; 590 mg/m^3; as STEL: 300 ppm; 885 mg/m^3 (ACGIH 1997).
MAK: 200 ppm; 590 mg/m^3; D (1992)
OSHA PEL: TWA 200 ppm (590 mg/m^3)
NIOSH REL: TWA 200 ppm (590 mg/m^3) ST 300 ppm (885 mg/m^3)
NIOSH IDLH: 3000 ppm

ROUTES OF EXPOSURE:
The substance can be absorbed into the body by inhalation and by ingestion.

INHALATION RISK:
A harmful contamination of the air can be reached rather quickly on evaporation of this substance at 20°C.

EFFECTS OF SHORT-TERM EXPOSURE:
The substance irritates the eyes and the respiratory tract. The substance may cause effects on the central nervous system. Exposure far above the OEL may result in unconsciousness.

EFFECTS OF LONG-TERM OR REPEATED EXPOSURE:
The liquid defats the skin. Animal tests show that this substance possibly causes toxic effects upon human reproduction.

PHYSICAL PROPERTIES	Boiling point: 80°C Melting point: -86°C Relative density (water = 1): 0.8 Solubility in water, g/100 ml at 20°C: 29 Vapour pressure, kPa at 20°C: 10.5 Relative vapour density (air = 1): 2.41	Relative density of the vapour/air-mixture at 20°C (air = 1): 1.1 Flash point: -9°C (c.c.) Auto-ignition temperature: 505°C Explosive limits, vol% in air: 1.8-11.5 Octanol/water partition coefficient as log Pow: 0.29
ENVIRONMENTAL DATA		

N O T E S

The odour warning when the exposure limit value is exceeded is insufficient.

Transport Emergency Card: TEC (R)-88.
NFPA Code: H1; F3; R0.

This card contains the collective views of the IPCS Peer Review Committee and may not reflect in all cases all the detailed requirements included in national legislation on the subject. The user should verify compliance of the cards with the relevant legislation in the country of use. The only modifications made to produce the U.S. version is inclusion of the OSHA PELs, NIOSH RELs and IDLH values.

Level 1

Chemical Name: Methyl Ethyl Ketone

CAS Registry Number: 78-93-3

NTP CHEMICAL REPOSITORY (RADIAN CORPORATION, AUGUST 29, 1991)
METHYL ETHYL KETONE

-IDENTIFIERS
 ===========

*CATALOG ID NUMBER: 001254

*CAS NUMBER: 78-93-3

*BASE CHEMICAL NAME: METHYLETHYLKETONE

*PRIMARY NAME: METHYL ETHYL KETONE

*CHEMICAL FORMULA: C4H8O

*STRUCTURAL FORMULA: CH3COCH2CH3

*WLN: 2V1

*SYNONYMS:
  2-BUTANONE
  BUTANONE
  ETHYL METHYL KETONE
  KETONE, ETHYL METHYL
  METHYL ACETONE
  MEK
  MEETCO
  RCRA WASTE NUMBER U159
  UN 1193
  UN 1232

-PHYSICAL CHEMICAL DATA
 ======================

*PHYSICAL DESCRIPTION: LITERATURE: Clear colorless liquid
REPOSITORY: Clear colorless liquid

*MOLECULAR WEIGHT: 72.11

*SPECIFIC GRAVITY: 0.805 @ 20/4 C [031,055,062,421]

*DENSITY: 0.806 g/mL @ 20 C [371]

*MP (DEG C): -86.3 C [017,047,371]

*BP (DEG C): 79.6 C [017,031,055,205,371]

*SOLUBILITIES:
WATER : >=100 mg/mL @ 19 C (RAD)

DMSO : >=100 mg/mL @ 19 C (RAD)

95% ETHANOL : >=100 mg/mL @ 19 C (RAD)

METHANOL : Not available

ACETONE : >=100 mg/mL @ 19 C (RAD)

TOLUENE : Not available

OTHER SOLVENTS:
Benzene: Miscible [031,205]
Ether: Miscible [031,205]
Industrial organic solvents: Soluble [421]
Oils: Miscible [062]

*VOLATILITY:
Vapor pressure: 77.5 mm Hg @ 20 C [055,421,430]; 100 mm Hg @ 25.0 C [038]
Vapor density : 2.42 [043]

*FLAMMABILITY(FLASH POINT):
This chemical has a flash point of -3 C (26 F) [205,269,275]. It is flammable. Fires involving this material can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. A water spray may also be used [036,269,451]. The autoignition temperature is 515 C (960 F) [036,043,051,062, 421].

*UEL: 10% [036,051,062] LEL: 1.8% [043,058,066,430]

*REACTIVITY:
This chemical is incompatible with strong oxidizers [058,269,346]. It is also incompatible with chlorosulfonic acid, oleum, hydrogen peroxide, and nitric acid [043]. It can react with potassium tert-butoxide and with chloroform [043,066]. It can also react with bases and strong reducing agents [269]. Vigorous reactions occur with chloroform in the presence of bases, and explosive peroxides are formed with (hydrogen peroxide + nitric acid) [036]. It is also incompatible with 2-propanol [066].

*STABILITY:
This chemical is stable under normal laboratory conditions. Solutions of this chemical in water, DMSO, 95% ethanol or acetone should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Specific gravity: 0.7997 @ 25/4 C; 0.8255 @ 20/4 C [062]
Specific gravity: 0.80615 @ 20/20 C [043,051]
Boiling point: 30 C @ 119 mm Hg [017]
Refractive index: 1.3788 @ 20 C [047]; 1.3814 @ 15 C [026]
Fragrant, mint-like, moderately sharp odor [346]
Odor threshold: 2 ppm [055,430]
log P octanol: 0.26 [055]
Specific heat: 0.549 cal/g [062]
Viscosity: 0.40 centipoise @ 25 C [062]
Constant boiling mixture with water (88.7%) with a boiling point of 73.4 C [[031]
Lambda max: 400-350 nm, 340 nm, 330 nm (A=0.01, 0.10, 1.0) [275]

-TOXICITY
========

*NIOSH REGISTRY NUMBER: EL6475000

*TOXICITY:

typ. dose	mode	specie	amount	units	other
TCLo	ihl	hmn	100	ppm/5M	
LC50	ihl	mus	40	gm/m3/2H	
LC50	ihl	rat	23500	mg/m3/8H	
LDLo	ipr	gpg	2000	mg/kg	

LD50	ipr	mus	616	mg/kg
LD50	orl	mus	4050	mg/kg
LD50	orl	rat	2737	mg/kg
LD50	skn	rbt	6480	mg/kg
LC50	ihl	mam	38	gm/m3
LD50	ipr	rat	607	mg/kg

*AQTX/TLM96: over 1000 ppm

*SAX TOXICITY EVALUATION:
THR: Moderately toxic by ingestion, skin contact and intraperitoneal routes. Human systemic effects by inhalation. An experimental teratogen. Experimental reproductive effects. A strong irritant. Human eye irritation @ 350 ppm. Affects peripheral nervous system and central nervous system.

*CARCINOGENICITY: Not available

*MUTATION DATA:

test	lowest dose	test	lowest dose
sln-smc	33800 ppm		

*TERATOGENICITY:
Reproductive Effects Data:
TCLo: ihl-rat 3000 ppm/7H (6-15D preg)
TCLo: ihl-rat 1000 ppm/7H (6-15D preg)

*STANDARDS, REGULATIONS & RECOMMENDATIONS:
OSHA: Federal Register (1/19/89) and 29 CFR 1910.1000 Subpart Z
Transitional Limit: PEL-TWA 200 ppm [610]
Final Limit: PEL-TWA 200 ppm; STEL 300 ppm [610]
ACGIH: TLV-TWA 200 ppm; STEL 300 ppm [015,415,421,610]
NIOSH Criteria Document: Recommended Exposure Limit to this compound-air: TWA 200 ppm [610]
NFPA Hazard Rating: Health (H): 1
Flammability (F): 3
Reactivity (R): 0
H1: Materials only slightly hazardous to health (see NFPA for details).
F3: Materials which can be ignited under almost all normal temperature conditions (see NFPA for details).
R0: Materials which are normally stable even under fire exposure conditions and which are not reactive with water (see NFPA for details).

*OTHER TOXICITY DATA:
Skin and Eye Irritation Data:
eye-hmn 350 ppm
skn-rbt 500 mg/24H MOD
skn-rbt 402 mg/24H MLD
skn-rbt 13780 ug/24H open MLD
eye-rbt 80 mg
Review: Toxicology Review
Standards and Regulations: DOT-Hazard: Flammable liquid; Label: Flammable liquid
Status: EPA Genetox Program 1988, Inconclusive: B subtilis rec assay
EPA TSCA Chemical Inventory, 1986
EPA TSCA 8(a) Preliminary Assessment Information, Final Rule
EPA TSCA Test Submission (TSCATS) Data Base, January 1989

NIOSH Analytical Methods: see 2-Butanone, Ethanol, and Toluene in blood, 8002

Meets criteria for proposed OSHA Medical Records Rule

-OTHER DATA (Regulatory)
 ========================

*PROPER SHIPPING NAME (IATA): Ethyl methyl ketone

*UN/ID NUMBER: UN1193

*HAZARD CLASS: 3 SUBSIDIARY RISK: None PACKING GROUP: II

*LABELS REQUIRED: Flammable liquid

*PACKAGING: PASSENGER: PKG. INSTR.: 305, Y305 MAXIMUM QUANTITY: 5 L, 1 L
CARGO : PKG. INSTR.: 307 MAXIMUM QUANTITY: 60 L

*SPECIAL PROVISIONS: None

*USES:
This compound is used as a solvent in nitrocellulose coating and vinyl film manufacture, in smokeless powder manufacture, in cements and adhesives, dewaxing of lubricating oils, "Glyptal" resins, paint removers, organic synthesis, cleaning fluids, acrylic coatings; intermediate in drug manufacture; manufacture of colorless synthetic resins; swelling agent of resins; intermediate in the manufacture of ketones and amines; and printing catalyst and carrier.

*COMMENTS: Not available

-HANDLING PROCEDURES
 ====================

*ACUTE/CHRONIC HAZARDS:
This compound may be harmful by inhalation, ingestion or skin absorption. It is a severe irritant of the skin and eyes [269]. It is also an irritant of the mucous membranes and upper respiratory tract [151,269]. When heated to decomposition it emits toxic fumes of carbon monoxide and carbon dioxide [269].

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS:
Permeation Test Results For The Neat (Undiluted) Chemical:
The permeation test results for the neat (undiluted) chemical are given below. The breakthrough times of this chemical are given for each glove type tested. The table is a presentation of actual test results, not specific recommendations or suggestions. Avoid glove types which exhibit breakthrough times of less than the anticipated task time plus an adequate safety factor. If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.

Glove Type	Model Number	Thickness	Breakthrough Time
Butyl rubber	North B-174	0.61 mm	480 min
PVA	Edmont 25-545	0.69 mm	320 min
Neoprene	Edmont 29-870	0.51 mm	10 min
Latex	Ackwell 5-109	0.13 mm	1 min

*RECOMMENDED RESPIRATOR:
When working with this chemical, wear a NIOSH-approved full face chemical cartride respirator equipped with the appropriate organic vapor

cartridges. If that is not available, a half face respirator similarly equipped plus airtight goggles can be substituted. However, please note that half face respirators provide a substantially lower level of protection than do full face respirators.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should store this chemical in an explosion-proof refrigerator and keep it away from oxidizing materials. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you spill this chemical, FIRST REMOVE ALL SOURCES OF IGNITION. Then, use absorbent paper to pick up all liquid spill material. Seal the absorbent paper, as well as any of your clothing which may be contaminated, in a vapor-tight plastic bag for eventual disposal. Wash any surfaces you may have contaminated with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT: Not available

-EMERGENCY PROCEDURES
==========

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. Volatile chemicals have a high risk of being aspirated into the victim's lungs during vomiting which increases the medical problems.
If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a hospital or poison control center. IMMEDIATELY transport the victim to a hospital.
If the victim is convulsing or unconscious, do not give anything by mouth,

ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport the victim to a hospital.

*SYMPTOMS:

Symptoms of exposure to this compound may include severe irritation of the eyes, irritation of the skin and upper respiratory tract, headache, dizziness and nausea [058,269]. Other symptoms may include weakness, fatigue, possible respiratory arrest, diarrhea, vomiting, stomach and/or intestinal irritation and unconsciousness [058]. It may cause irritation of the nose and throat, diminished vision, mild vertigo and narcosis [430]. It may also cause central nervous system effects and neuropathy [301]. It may irritate the mucous membranes [151]. Prolonged exposure may produce central nervous system depression [430]. Repeated exposure is reported to cause permanent brain and nervous system damage [058]. Eye contact may result in slight conjunctival hyperemia developing to severe anterior uveitis [099]. It may also result in corneal injury. Prolonged skin contact may defat the skin and produce dermatitis [430]. A drop in rabbit eyes has produced moderate reversible injury [099].

HAZARDOUS SUBSTANCE FACT SHEET

Common Name: **METHYL ETHYL KETONE**

CAS Number: 78-93-3
DOT Number: UN 1193

RTK Substance number: 1258
Date: February 1989 Revision: September 1996

HAZARD SUMMARY

* **Methyl Ethyl Ketone** can affect you when breathed in and by passing through your skin.
* **Methyl Ethyl Ketone** can irritate the skin causing a rash and burning feeling on contact. Repeated exposure can cause drying and cracking of the skin.
* Contact can severely irritate and burn the eyes, leading to permanent damage.
* Exposure to the vapor can irritate the eyes, nose, mouth, and throat causing coughing and wheezing.
* Exposure can cause dizziness, lightheadedness, headache, nausea, blurred vision, and may cause you to pass out.
* Repeated exposure can damage the nervous system and may affect the brain.
* **Methyl Ethyl Ketone** is a FLAMMABLE LIQUID.

IDENTIFICATION

Methyl Ethyl Ketone is a colorless liquid with a fragrant, mint-like odor. It is used as a solvent and in making plastics, textiles, and paints.

REASON FOR CITATION

* **Methyl Ethyl Ketone** is on the Hazardous Substance List because it is regulated by OSHA and cited by ACGIH, DEP, DOT, NIOSH, NFPA, HHAG and EPA.
* Definitions are provided on page 5.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

The New Jersey Right to Know Act requires most employers to label chemicals in the workplace and requires public employers to provide their employees with information and training concerning chemical hazards and controls. The federal OSHA Hazard Communication Standard, 1910.1200, requires private employers to provide similar training and information to their employees.

* Exposure to hazardous substances should be routinely evaluated. This may include collecting air samples. Under OSHA 1910.20, you have a legal right to obtain copies of sampling results from your employer.
* If you think you are experiencing any work-related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.

---

* **ODOR THRESHOLD = 5.4 ppm**.
* The range of accepted odor threshold values is quite broad. Caution should be used in relying on odor alone as a warning of potentially hazardous exposures.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is **200 ppm** averaged over an 8-hour workshift.

NIOSH: The recommended airborne exposure limit is **200 ppm** averaged over a 10-hour workshift and **300 ppm** not to be exceeded during any 15 minute work period.

ACGIH: The recommended airborne exposure limit is **200 ppm** averaged over an 8-hour workshift and **300 ppm** as a STEL (short term exposure limit).

* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* Wear protective work clothing.
* Wash thoroughly immediately after exposure to **Methyl Ethyl Ketone** and at the end of the workshift.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of **Methyl Ethyl Ketone** to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to **Methyl Ethyl Ketone**:

* **Methyl Ethyl Ketone** can irritate the skin causing a rash and burning feeling on contact.
* Contact can severely irritate and burn the eyes, leading to permanent damage.
* Exposure to the vapor can irritate the eyes, nose, mouth, and throat causing coughing and wheezing.
* Exposure can cause dizziness, lightheadedness, headache, nausea, blurred vision, and may cause you to pass out.

Chronic Health Effects

The following chronic (long-term) health effects can occur at some time after exposure to **Methyl Ethyl Ketone** and can last for months or years:

Cancer Hazard

* According to the information presently available to the New Jersey Department of Health and Senior Services, **Methyl Ethyl Ketone** has not been tested for its ability to cause cancer in animals.

Reproductive Hazard

* There is limited evidence that **Methyl Ethyl Ketone** is a teratogen in animals. Until further testing has been done, it should be treated as a possible teratogen in humans.

Other Long-Term Effects

* Repeated exposure can damage the nervous system and may affect the brain. Effects may include reduced memory and concentration, personality changes (withdrawal, irritability), fatigue, sleep disturbances, reduced coordination, and/or effects on nerves supplying internal organs (autonomic nerves) and/or nerves to the arms and legs (weakness, "pins and needles").
* Repeated exposure can cause drying and cracking of the skin.

MEDICAL

Medical Testing

If symptoms develop or overexposure is suspected, the following may be useful:

* Interview for brain effects, including recent memory, mood (irritability, withdrawal), concentration, headaches, malaise and altered sleep patterns. Consider cerebellar, autonomic and peripheral nervous system evaluation. Positive and borderline individuals should be referred for neuropsychological testing.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

Request copies of your medical testing. You have a legal right to this information under OSHA 1910.20.

Mixed Exposures

Methyl Ethyl Ketone in combination with *Methyl Butyl Ketone* and possibly other solvents can damage the nervous system.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, **ENGINEERING CONTROLS** are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the controls mentioned above, but is sometimes necessary.

In evaluating the controls present in your workplace, consider: (1) how hazardous the substance is, (2) how much of the substance is released into the workplace and (3) whether harmful skin or eye contact could occur. Special controls should be in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically pump liquid **Methyl Ethyl Ketone** from drums or other storage containers to process containers.
* Specific engineering controls are recommended for this chemical by NIOSH. Refer to the NIOSH criteria document: *Ketones #78-173*.

Good **WORK PRACTICES** can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by **Methyl Ethyl Ketone** should change into clean clothing promptly.
* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to **Methyl Ethyl Ketone**.
* Eye wash fountains should be provided in the immediate work area for emergency use.
* If there is the possibility of skin exposure, emergency shower facilities should be provided.
* On skin contact with **Methyl Ethyl Ketone**, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted **Methyl Ethyl Ketone**, whether or not known skin contact has occurred.
* Do not eat, smoke, or drink where **Methyl Ethyl Ketone** is handled, processed, or stored, since the chemical can be swallowed. Wash hands carefully before eating, drinking, smoking or using the toilet.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT. However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with **Methyl Ethyl Ketone**. Wear solvent-resistant gloves and clothing. Safety equipment suppliers/manufacturers can provide recommendations on the most protective glove/clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.
* ACGIH recommends the use of *Butyl Rubber* materials in protective clothing.

Eye Protection

* Wear splash-proof chemical goggles and face shield when working with liquid, unless full facepiece respiratory protection is worn.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* Where the potential exists for exposures over **200 ppm**, use a MSHA/NIOSH approved full facepiece respirator with an organic vapor cartridge/canister. More protection is provided by a full facepiece respirator than by a half-mask respirator, and even greater protection is provided by a powered-air purifying respirator.
* If while wearing a filter, cartridge or canister respirator, you can smell, taste, or otherwise detect **Methyl Ethyl Ketone**, or in the case of a full facepiece respirator you experience eye irritation, leave the area immediately. Check to make sure the respirator-to-face seal is still good. If it is, replace the filter, cartridge, or canister. If the seal is no longer good, you may need a new respirator.
* Be sure to consider all potential exposures in your workplace. You may need a combination of filters, prefilters, cartridges, or canisters to protect against different forms of a chemical (such as vapor and mist) or against a mixture of chemicals.
* Where the potential for high exposures exists, use a MSHA/NIOSH approved supplied-air respirator with a full facepiece operated in a pressure-demand or other positive-pressure mode. For increased protection use in combination with an auxiliary self-contained breathing apparatus operated in a pressure-demand or other positive-pressure mode.
* Exposure to **3,000 ppm** is immediately dangerous to life and health. If the possibility of exposure above **3,000 ppm** exists, use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in a pressure-demand or other positive-pressure mode.

HANDLING AND STORAGE

* Prior to working with **Methyl Ethyl Ketone** you should be trained on its proper handling and storage.
* **Methyl Ethyl Ketone** must be stored to avoid contact with STRONG OXIDIZERS (such as CHLORINE, BROMINE and FLUORINE) since violent reactions occur.
* Store in tightly closed containers in a cool, well-ventilated area away from HEAT, SPARKS or FLAME.

* Sources of ignition, such as smoking and open flames, are prohibited where **Methyl Ethyl Ketone** is used, handled, or stored in a manner that could create a potential fire or explosion hazard.
* Metal containers involving the transfer of **Methyl Ethyl Ketone** should be grounded and bonded. Drums must be equipped with self-closing valves, pressure vacuum bungs, and flame arresters.
* Use only non-sparking tools and equipment, especially when opening and closing containers of **Methyl Ethyl Ketone**.

QUESTIONS AND ANSWERS

Q: If I have acute health effects, will I later get chronic health effects?
A: Not always. Most chronic (long-term) effects result from repeated exposures to a chemical.

Q: Can I get long-term effects without ever having short-term effects?
A: Yes, because long-term effects can occur from repeated exposures to a chemical at levels not high enough to make you immediately sick.

Q: What are my chances of getting sick when I have been exposed to chemicals?
A: The likelihood of becoming sick from chemicals is increased as the amount of exposure increases. This is determined by the length of time and the amount of material to which someone is exposed.

Q: When are higher exposures more likely?
A: Conditions which increase risk of exposure include physical and mechanical processes (heating, pouring, spraying, spills and evaporation from large surface areas such as open containers), and "confined space" exposures (working inside vats, reactors, boilers, small rooms, etc.).

Q: Is the risk of getting sick higher for workers than for community residents?
A: Yes. Exposures in the community, except possibly in cases of fires or spills, are usually much lower than those found in the workplace. However, people in the community may be exposed to contaminated water as well as to chemicals in the air over long periods. Because of this, and because of exposure of children or people who are already ill, community exposures may cause health problems.

Q: Can men as well as women be affected by chemicals that cause reproductive system damage?
A: Yes. Some chemicals reduce potency or fertility in both men and women. Some damage sperm and eggs, possibly leading to birth defects.

Q: Who is at the greatest risk from reproductive hazards?
A: Pregnant women are at greatest risk from chemicals that harm the developing fetus. However, chemicals may affect the ability to have children, so both men and women of childbearing age are at high risk.

Q: Should I be concerned if a chemical is a teratogen in animals?
A: Yes. Although some chemicals may affect humans differently than they affect animals, damage to animals suggests that similar damage can occur in humans.

The following information is available from:

New Jersey Department of Health and
Senior Services
Occupational Disease and Injury Services
Trenton, NJ 08625-0360
(609) 984-1863

Industrial Hygiene Information

Industrial hygienists are available to answer your questions regarding the control of chemical exposures using exhaust ventilation, special work practices, good housekeeping, good hygiene practices, and personal protective equipment including respirators. In addition, they can help to interpret the results of industrial hygiene survey data.

Medical Evaluation

If you think you are becoming sick because of exposure to chemicals at your workplace, you may call a Department of Health and Senior Services physician who can help you find the services you need.

Public Presentations

Presentations and educational programs on occupational health or the Right to Know Act can be organized for labor unions, trade associations and other groups.

Right to Know Information Resources

The Right to Know Infoline (609) 984-2202 can answer questions about the identity and potential health effects of chemicals, list of educational materials in occupational health, references used to prepare the Fact Sheets, preparation of the Right to Know survey, education and training programs, labeling requirements, and general information regarding the Right to Know Act. Violations of the law should be reported to (609) 984-2202.

DEFINITIONS

ACGIH is the American Conference of Governmental Industrial Hygienists. It recommends upper limits (called TLVs) for exposure to workplace chemicals.

A **carcinogen** is a substance that causes cancer.

The **CAS number** is assigned by the Chemical Abstracts Service to identify a specific chemical.

A **combustible** substance is a solid, liquid or gas that will burn.

A **corrosive** substance is a gas, liquid or solid that causes irreversible damage to human tissue or containers.

DEP is the New Jersey Department of Environmental Protection.

DOT is the Department of Transportation, the federal agency that regulates the transportation of chemicals.

EPA is the Environmental Protection Agency, the federal agency responsible for regulating environmental hazards.

A **fetus** is an unborn human or animal.

A **flammable** substance is a solid, liquid, vapor or gas that will ignite easily and burn rapidly.

The **flash point** is the temperature at which a liquid or solid gives off vapor that can form a flammable mixture with air.

HHAG is the Human Health Assessment Group of the federal EPA.

IARC is the International Agency for Research on Cancer, a scientific group that classifies chemicals according to their cancer-causing potential.

A **miscible** substance is a liquid or gas that will evenly dissolve in another.

mg/m^3 means milligrams of a chemical in a cubic meter of air. It is a measure of concentration (weight/volume).

MSHA is the Mine Safety and Health Administration, the federal agency that regulates mining. It also evaluates and approves respirators.

A **mutagen** is a substance that causes mutations. A **mutation** is a change in the genetic material in a body cell. Mutations can lead to birth defects, miscarriages, or cancer.

NAERG is the North American Emergency Response Guidebook. It was jointly developed by Transport Canada, the United States Department of Transportation and the Secretariat of Communications and Transportation of Mexico. It is a guide for first responders to quickly identify the specific or generic hazards of material involved in a transportation incident, and to protect themselves and the general public during the initial response phase of the incident.

NCI is the National Cancer Institute, a federal agency that determines the cancer-causing potential of chemicals.

NFPA is the National Fire Protection Association. It classifies substances according to their fire and explosion hazard.

NIOSH is the National Institute for Occupational Safety and Health. It tests equipment, evaluates and approves respirators, conducts studies of workplace hazards, and proposes standards to OSHA.

NTP is the National Toxicology Program which tests chemicals and reviews evidence for cancer.

OSHA is the Occupational Safety and Health Administration, which adopts and enforces health and safety standards.

PEOSHA is the Public Employees Occupational Safety and Health Act, a state law which sets PELs for New Jersey public employees.

ppm means parts of a substance per million parts of air. It is a measure of concentration by volume in air.

A **reactive** substance is a solid, liquid or gas that releases energy under certain conditions.

A **teratogen** is a substance that causes birth defects by damaging the fetus.

TLV is the Threshold Limit Value, the workplace exposure limit recommended by ACGIH.

The **vapor pressure** is a measure of how readily a liquid or a solid mixes with air at its surface. A higher vapor pressure indicates a higher concentration of the substance in air and therefore increases the likelihood of breathing it in.

>>>>>>>>>>>>>>>>> EMERGENCY INFORMATION <<<<<<<<<<<<<<<<<

Common Name: **METHYL ETHYL KETONE**
DOT Number: **UN 1193**
NAERG Code: **127**
CAS Number: **78-93-3**

Hazard rating	NJ DOH	NFPA
FLAMMABILITY	-	3
REACTIVITY	-	0
POISONOUS GASES ARE PRODUCED IN FIRE CONTAINERS MAY EXPLODE IN FIRE		

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* **Methyl Ethyl Ketone** is a FLAMMABLE LIQUID.
* Use dry chemical, CO_2, or alcohol foam extinguishers. Water should be used to keep fire-exposed containers cool.
* POISONOUS GASES ARE PRODUCED IN FIRE.
* Vapors may travel to a source of ignition and flash back.
* CONTAINERS MAY EXPLODE IN FIRE.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If **Methyl Ethyl Ketone** is spilled or leaked, take the following steps:

* Evacuate and isolate the area of the spill or leak, and restrict persons not wearing protective equipment from area of spill or leak until clean-up is complete.
* Remove all ignition sources.
* Ventilate area of spill or leak.
* Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
* Keep **Methyl Ethyl Ketone** out of a confined space, such as a sewer, because of the possibility of an explosion, unless the sewer is designed to prevent the build-up of explosive concentrations.
* It may be necessary to contain and dispose of **Methyl Ethyl Ketone** as a HAZARDOUS WASTE. Contact your Department of Environmental Protection (DEP) or your regional office of the federal Environmental Protection Agency (EPA) for specific recommendations.
* If employees are required to clean-up spills, they must be properly trained and equipped. OSHA 1910.120(q) may be applicable.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department. You can request emergency information from the following:

CHEMTREC: (800) 424-9300
NJDEP HOTLINE: (609) 292-7172

==========

HANDLING AND STORAGE (See page 3)

FIRST AID

In NJ, POISON INFORMATION 1-800-962-1253

Eye Contact

* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids. Seek medical attention.

Skin Contact

* Quickly remove contaminated clothing. Immediately wash area with large amounts of water. Seek medical attention.

Breathing

* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

PHYSICAL DATA

Vapor Pressure: 70.6 mm Hg at 68^{O}F (20^{O}C)
Flash Point: 21^{O}F (-6.1^{O}C)
Water Solubility: Soluble

OTHER COMMONLY USED NAMES

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

TOLUENE (108-88-3)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards**

		Reference(s)
Recognized:	Developmental Toxicant	P65
Suspected:	Cardiovascular or Blood Toxicant	EPA-HEN KLAA RTECS
	Gastrointestinal or Liver Toxicant	RTECS
	Immunotoxicant	IPCS
	Kidney Toxicant	KLAA RTECS STAC
	Neurotoxicant	DAN EPA-HEN FELD OEHHA-2000 OEHHA-AREL RTECS
	Reproductive Toxicant	EPA-SARA
	Respiratory Toxicant	EPA-HEN LU OEHHA-2000 OEHHA-AREL
	Skin or Sense Organ Toxicant	EPA-HEN OEHHA-AREL

- **Hazard Rankings**

  More hazardous than most chemicals in 3 out of 10 ranking systems.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.
  Used in at least 13 industries.
  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.

- **Profile of Environmental Release and Waste Generation**

  For a list of the geographic areas, facilities, or industrial sectors which report the largest releases or transfers of this chemical to the Toxics Release Inventory, select what you want:

  - Rank States
  - Rank Counties
  - Rank Zip Codes
  - Rank Facilities
  - Rank Industrial Sectors

- **Regulatory Coverage**

  On at least 7 federal regulatory lists.

- **Basic Testing to Identify Chemical Hazards**

  Eight basic tests to identify chemical hazards have been conducted and are publicly

available for this chemical.

- **Information Needed for Safety Assessment**

  Possesses all the national data required for safety assessment.
  Scorecard has risk assessment data for this chemical.

- **Links**

  Additional information about this chemical may be available elsewhere in Scorecard.

Immunotoxicity Definitions

from the Health Effects section of Scorecard

Immunotoxicity is defined as adverse effects on the functioning of the immune system that result from exposure to chemical substances. Altered immune function may lead to the increased incidence or severity of infectious diseases or cancer, since the immune system's ability to respond adequately to invading agents is suppressed. Identifying immunotoxicants is difficult because chemicals can cause a wide variety of complicated effects on immune function. Observations in humans and studies in rodents have clearly demonstrated that a number of environmental and industrial chemicals can adversely affect the immune system. Exposure to asbestos, benzene, and halogenated aromatic hydrocarbons such as polybrominated biphenyls (PBBs), polychlorinated biphenyls (PCBs), and dioxins (TCDD) can lead to immunosuppression in humans. Toxic agents can also cause autoimmune diseases, in which healthy tissue is attacked by an immune system that fails to differentiate self-antigens from foreign antigens. For example, the pesticide dieldrin induces an autoimmune response against red blood cells, resulting in hemolytic anemia.

Also considered to be immunotoxicants, allergens are compounds that stimulate the immune system and can cause hypersensitivity reactions or allergies. Many chemicals induce allergic reactions in humans and experimental animals, producing a variety of clinical manifestations, such as asthma, rhinitis, and anaphylaxis. The industrial chemical toluene diisocyanate (TDI) and metals such as nickel and beryllium are notable examples of allergenic agents.

Consumer Products

that contain TOLUENE (108-88-3) from Scorecard

What kinds of consumer products may contain this chemical?

- Adhesive films, all types, incl pressure sensitive
- Aerosol paint concentrates
- Architectural coatings
- Auto, other transportation, and machinery refinish paints incl primers
- Automobile body polish and cleaners
- Floor polish
- Furniture polish and cleaners
- General performance sealants (PVAC, butyl, vinyl, etc.)
- Gravure inks
- Ground/traffic marking coatings
- Household hard surface cleaners (aerosol)
- Household hard surface cleaners (liquid)
- Industrial interior coatings
- Industrial particleboard (furniture, fixtures, cabinets, etc.)
- Laundry starch preparations
- Leather dressings and finishes (excl shoe polish)
- Loose mineral wool fiber (blowing and pouring)
- Lubricating oils
- Misc. use aromatics
- Miscellaneous paint-related products
- Moisturizing creams
- Nail enamels and polishes
- Non-wood upholstered office side and arm chairs
- Nonstructural caulking compounds and sealants
- Other art materials incl clay, water & tempera colors, finger paint, etc.
- Other automotive chemicals
- Other gravure inks
- Other industrial chemical specialty products
- Other laundry aids, icluding ironing aids and dry cleaning spotting pre
- Other manicuring preparations
- Other miscellaneous allied paint products, including brush cleaners
- Other specialty cleaning and sanitation products

- Packaging inks: solvent types
- Packaging inks: solvent types
- Paint and varnish removers
- Paint thinners
- Paints and allied products
- Phenolic and phenolic derivative adhesives
- Polyvinyl acetate (latex type) adhesives
- Publication inks: solvent types
- Scatter rugs, bathmats, and sets (rugs 6 x 9 ft and smaller)
- Sheet vinyl flooring
- Shoe polishes and cleaners
- Solvent thinned exterior stains incl shingle and shake
- Solvent thinned exterior undercoaters and primers
- Solvent thinned interior clear finishes
- Solvent thinned interior stains
- Solvent thinned interior undercoaters and primers
- Specialty performance sealants
- Surfactants, finishing agents, and assistants
- Synthetic resin and rubber adhesives
- Thick line coloring pens and markers
- Urethane adhesives
- Wall coverings
- Waterproofing compounds
- Wood office furniture
- Wood office secretarial chairs
- Wood office work surfaces (modular systems)

Basic Testing to Identify Chemical Hazards

for TOLUENE (108-88-3) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

More on the importance of basic toxicity testing

Public Health Statement

Toluene

ATSDR Public Health Statement, December 1989

What is toluene?

Toluene is a clear, colorless liquid with a sweet smell. Toluene occurs naturally in crude oil and the tolu tree. It is produced from petroleum refining, as a by-product of styrene production, and as a by-product of coke-oven operations. Industry uses it in refining gasoline, chemical manufacturing, and manufacture of paints, lacquers, adhesives, rubber, and in some printing and leather tanning processes. Toluene is usually disposed of at hazardous waste sites as a used solvent (a substance used to dissolve other substances). Toluene doesn't usually stay in the environment; it readily breaks down in soil and evaporates from water.

How might I be exposed to toluene?

Humans may be exposed to toluene from many sources, including drinking water, food, air, workplaces, and consumer products. Exposure to toluene by humans occurs mostly through breathing the chemical in the workplace or during deliberate glue sniffing or solvent abuse. Toluene readily evaporates and can therefore be released to the air when toluene-containing products are used. Automobile exhaust can also be a significant source of toluene emissions to the air. Petrochemical workers, workers in the chemical industry, dye makers, and paint workers are at the greatest risk of exposure. Because toluene is a common solvent and is found in many consumer products, exposures may happen in the home and outdoors. Consumer products containing toluene include gasoline, nail polish, cosmetics, rubber cement, paint brush cleaners, stain removers, fabric dyes, inks, and adhesives. Smokers are exposed to toluene in cigarette smoke.

Exposure may happen at some hazardous waste sites. The U.S. Environmental Protection Agency (EPA) conducted a survey in 1988 and found toluene in groundwater, surface water, or soil at 29% of the hazardous waste sites surveyed. The average amounts of toluene at hazardous waste sites were 21 ppb (21 parts toluene per billion parts water) in groundwater and 7.5 ppb in surface water. The amount in soil was 77 ppb.

Federal and state surveys do not show toluene to be a widespread contaminant of drinking water supplies. Toluene was found in about 1% of the groundwater sources at amounts lower than 2 ppb. More was found in surface water supplies, but the surveys were not as complete as the groundwater surveys. Toluene levels in the air are typically lower than 1 ppm (one part toluene per million parts air) in nonindustrialized areas (cities and suburbs). Usual levels of toluene indoors are also lower than 1 ppm. Usual levels in food have not been reported.

How can toluene enter and leave my body?

Toluene can enter the body by passing through the skin, or when a person breathes its vapors, or eats or drinks contaminated food or water. Human exposure occurs mainly by breathing air containing toluene. Where a person lives, works, and travels and what a person eats affect daily exposure to toluene. Things such as age, sex, and health status affect what happens to toluene once it is in the body. After being taken into the body, most toluene leaves the body within 12 hours. It leaves the body unchanged in the exhaled air and also leaves the body as a breakdown product in the urine.

How can toluene affect my health?

The most important health concern for humans from either intentional or occupational exposure to toluene is its harmful effects on the nervous system. These effects of toluene depend on both the amount and length of exposure. Short-term exposure to moderate amounts of toluene, such as in elevated workplace exposures, can produce fatigue, confusion, general weakness, drunken-type actions, memory loss, nausea, and loss of appetite. These symptoms disappear when exposure is stopped.

Short-term exposure to high amounts of toluene results first in light-headedness and euphoria. This is followed by dizziness, sleepiness, unconsciousness, and, in some cases, death because the person cannot breathe prior to death. When exposure is stopped before death, these symptoms disappear. Long-term exposure to low and moderate amounts of toluene has caused slight effects on the kidneys in some people, but these people were also exposed to other solvents at the same time and it is difficult to tell which chemical may have caused the effects. Long-term exposure to high amounts of toluene by intentional abuse has been linked with permanent damage to the brain. Effects such as problems with speech, vision, and hearing; loss of muscle control; loss of memory and balance; and reduced scores on psychological tests have been reported. Researchers have seen possible effects on resistance to disease in persons exposed to moderate and high amounts of chemical mixtures that contained toluene. However, it is not possible to tell exactly which chemical in the mixture may have caused the effects.

In animals, as in humans, the main effect of toluene is on the nervous system. Exposure of animals to moderate and high amounts of toluene also produces slightly harmful effects on the liver, kidneys, and lungs. Several studies have shown that the development of unborn animals is affected or harmed when high levels of toluene are breathed in by pregnant animals. However, when pregnant animals were fed high amounts of toluene, the unborn animals did not show any developmental problems. It is not known if toluene will harm an unborn child when a pregnant woman drinks water or breathes in air containing toluene because studies in people are not complete enough to measure this effect. The National Toxicology Program (NTP) found that toluene did not cause cancer in a long-term study in rats and mice.

Is there a medical test to determine whether I have been exposed to toluene?

Several tests have been used to find out if a person has been exposed to toluene. These include measuring toluene and its breakdown products in blood and in urine. These tests are not commonly available at a doctor's office, but are easily done by special laboratories. To decide whether workplace exposure to toluene has happened, measurements of one of its breakdown products in urine have been used within 12 hours after exposure. However, because several other chemicals are also changed to the same breakdown product within the body, this test may not show that toluene exposure has happened. Other things, such as the amount of body fat and body weight, the person's sex, and exposure conditions, may also change this estimate of the amount of toluene exposure.

What levels of exposure have resulted in harmful health effects?

Toluene can be smelled in air at a level of about 0.16 ppm and it can be smelled in water at a level of 0.04 ppm. In water, toluene can be tasted at a level of 0.04 ppm. Tables 1-1, 1-2, 1-3, and 1-4 show the relationship between exposure to toluene and known health effects. Minimal Risk Levels (MRLs) are also included in Table 1-1. These MRLs were derived based on animal data for both short-term and longer-term exposure. The MRLs provide a basis for comparison to levels of toluene which people might encounter either in the air or in food or drinking water. If a person is exposed to toluene at an amount below the MRL, it is not expected that harmful noncancer health effects will occur. Since these levels are based on information that is currently available, there is always some uncertainty associated with it. Also, since the method for deriving MRLs does not use any information about cancer, an MRL does not imply anything about the presence, absence, or level of risk of cancer.

What recommendations has the federal government made to protect human health?

The federal government has developed regulatory standards and advisories to protect people from the possible health effects of toluene in the environment. The Occupational Safety and Health Administration (OSHA) has set a limit of 100 ppm of toluene for air in the workplace, averaged for an 8-hour exposure per day over a 40-hour workweek. The American Conference of Governmental Industrial Hygienists (ACGIH) and the National Institute for Occupational Safety and Health (NIOSH) have recommended that toluene in the workplace not exceed 100 ppm (as an average level over 8 hours).

EPA has recommended that drinking water should not contain more than 20 ppm for 1 day or 3 ppm for 10 days or 1 ppm for lifetime consumption. Any release of more than 1000 lbs of this chemical to the environment must be reported to the National Response Center. More information on state guidelines for air and water are available from state environmental agencies.

Where can I get more information?

Material Safety Data Sheet
(University of Utah)

Agency for Toxic Substances and Disease Registry

This fact sheet answers the most frequently asked health questions about toluene. For more information, you may call the ATSDR Information Center at 1-800-447-1544. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to toluene happens mostly through breathing it in workplace air, in automobile exhaust, or during deliberate glue sniffing or solvent abuse. It is also used in many consumer products. Breathing high levels of toluene affects the brain and can cause headaches, confusion, dizziness, sleepiness, and memory loss. This chemical has been found in at least 869 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is toluene?
(Pronounced tol'yoo-een')

Toluene is a colorless liquid with a distinctive sweet and pungent smell. It occurs naturally in crude oil and in the tolu tree. You can smell toluene at 8 parts of toluene per million parts of air (ppm) and taste it in water at 0.04 ppm to 1 ppm.

Toluene is produced during the process of making gasoline and other fuels from crude oil, in making coke from coal, and as a by-product in the manufacture of styrene.

It is also used in making paints, paint thinners, fingernail polish, lacquers, adhesives, and rubber and in some printing and leather tanning processes.

What happens to toluene when it enters the environment?

- Toluene has been found in waste sites and landfills when discarded as used solvent or in paints, paint thinners, and nail polish.
- It does not stay in the environment long.
- It is readily broken down by microorganisms in the soil.
- It evaporates quickly from the soil and surface water into the air.
- Toluene in the air combines with oxygen to form benzaldehyde and cresol, which can be harmful to people.
- Toluene can be taken up by fish, shellfish, plants, and animals living in water, but high levels do not build up.

How might I be exposed to toluene?

- People may be exposed through breathing toluene in workplace air or in automobile exhaust.
- Sniffing glue or using solvents improperly could lead to high exposures.
- Breathing contaminated air or touching it when working with gasoline, kerosene, heating oil, paints, and lacquers puts people at the greatest risk of exposure to toluene in air and on the skin.
- High exposures can occur at home and outdoors while using gasoline, nail polish, rubber cement, paints, paintbrush cleaners, stain removers, fabric dyes, inks, and adhesives.
- Drinking contaminated water or breathing air near waste sites and landfills could lead to higher exposures.
- The amount of toluene in food is likely to be low.
- People are also exposed to toluene by breathing cigarette smoke that has small amounts of toluene in it.

How can toluene affect my health?

Toluene affects the brain. Low-to-moderate levels from long-term exposure can cause tiredness, confusion, weakness, drunken-type actions, memory loss, nausea and loss of appetite, and hearing loss.

Inhaling a high level of toluene in a short time can make you feel light-headed, dizzy, or sleepy. It can cause unconsciousness, and even death.

Repeated exposure to high levels can cause permanent brain and speech damage, vision and hearing problems, loss of muscle control, and poor balance. It can also cause memory loss and decreased mental ability.

Toluene also affects the kidneys.

Several studies have shown that unborn animals were harmed when high levels of toluene were breathed by their mothers. Babies can have neurologic problems and retarded growth and development if their mothers breathe a high level of toluene during pregnancy. We do not know if toluene harms the unborn child if the mother is exposed to low levels of toluene during pregnancy.

How likely is toluene to cause cancer?

The Department of Health and Human Services and the International Agency for Research on Cancer have not classified toluene for carcinogenic effects. Studies in workers and animals indicate that toluene does not cause cancer.

Is there a medical test to show whether I've been exposed to toluene?

Laboratory tests can detect toluene or its breakdown products in exhaled air, blood, or urine. These tests are only useful within 12 hours of exposure and do not tell if harmful effects will occur. These tests are not routinely available at your doctor's office.

Has the federal government made recommendations to protect human health?

The Environmental Protection Agency (EPA) has set a limit in drinking water of 1 ppm toluene. EPA recommends that children should not drink water containing more than 20 ppm toluene for 1 day, or 2 ppm for longer lengths of time (7 years). Adults should not drink water containing more than 7 ppm toluene for longer times.

The EPA requires that spills or accidental releases of toluene into the environment of 1,000 pounds or more must be reported to EPA.

The Occupational Safety and Health Administration (OSHA) set a maximum level of 200 ppm toluene in workplace air for an 8-hour workday, 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) recommends an exposure limit of 100 ppm of toluene in workplace air and the American Conference of Governmental Industrial Hygienists (ACGIH) recommends an exposure limit of 50 ppm in workplace air.

Glossary

Carcinogenic:

Ability to cause cancer.

Long-term:

Lasting one year or longer.

PPM:

Parts per million.

TOLUENE

Toluene is a federal hazardous air pollutant and was identified as a toxic air contaminant in April 1993 under AB 2728.

CAS Registry Number: 108-88-3

Molecular Formula: C_7H_8

Description

Toluene is a colorless, flammable, non-corrosive liquid with a benzene-like odor. It is insoluble in water and soluble in acetone, absolute alcohol, ether, chloroform, benzene, petroleum ether, glacial acetic acid, and carbon disulfide (HSDB, 1991).

Physical Properties of Toluene

Molecular Weight	92.13
Boiling Point	110.7 oC
Melting Point	-95 oC
Flash Point	40 oF (closed cup)
Vapor Density	3.2 (air = 1)
Vapor Pressure	36.7 mm Hg at 30 oC
Density/Specific Gravity	0.866 at 20/4 oC (water = 1)
Log Octanol/Water Partition Coefficient	2.69
Conversion Factor	1 ppm = 3.77 mg/m3

(HSDB, 1991; Merck, 1989; Sax, 1987; Sax, 1989; U.S. EPA, 1994a)

SOURCES AND EMISSIONS

A. Sources

Toluene is used in aviation gasoline and high-octane blending stock, and as a solvent for paints, coatings, gums and resins. Other sources include tobacco smoke, petroleum and coal production, use as a chemical intermediate, and for styrene production.

The primary stationary sources that have reported emissions of toluene in California are crude petroleum and natural gas extraction, petroleum refining, and household furniture manufacturing facilities (ARB, 1997b). Toluene has also been detected but not quantified in motor vehicle exhaust by the Air Resources Board (ARB) (ARB, 1995e).

Toluene was registered for use as a pesticide; however, as of January 1, 1987, it is no longer registered for pesticidal use in California (DPR, 1996).

B. Emissions

The total emissions of toluene from stationary sources in California are estimated to be at least 5.4 million pounds per year, based on data reported under the Air Toxics "Hot Spots" Program (AB 2588) (ARB, 1997b). In addition, ARB staff estimates that 12.6 million and 62 thousand pounds per year are emitted from area and natural sources, respectively (ARB, 1990b).

C. Natural Occurrence

Natural sources of toluene include volcanos, forest fires, and crude oil (HSDB, 1991).

AMBIENT CONCENTRATIONS

Toluene is routinely monitored by the statewide ARB air toxics network. The network's mean concentration of toluene from January 1996 through December 1996 is estimated to be 8.29 micrograms per cubic meter (µg/m3) or 2.2 parts per billion (ppb) (ARB 1997c).

The United States Environmental Protection Agency (U.S. EPA) has also reported concentrations of toluene from 14 study areas during 1989 to 1991. The overall mean concentration from these areas was 10.2 µg/m3 (2.7 ppb) (U.S. EPA 1993a).

INDOOR SOURCES AND CONCENTRATIONS

Environmental tobacco smoke (ETS) emissions of toluene were measured using six cigarette brands popular in California and one reference cigarette. Toluene had an average emission of 656 µg/cigarette (Daisey et al., 1994).

There have been studies that have measured toluene within vehicles. A southern California study measured an average toluene in-vehicle concentration of 136.5 µg/m3 (36.3 ppb) and a maximum concentration of 994.6 µg/m3 (264.5 ppb) during the summer of 1987 and winter of 1988 (Shikiya et al., 1989). Similar studies in Raleigh, North Carolina and Boston, Massachusetts measured average concentrations of 33.3 and 46.5 µg/m3 (8.9 and 12.4 ppb) and maximum concentrations of 105 and 118.9 µg/m3 (27.9 and 31.6 ppb), respectively (Chan et al., 1991a; Chan et al., 1991b). These studies found toluene concentrations to be 2 to 5 times greater than outdoor toluene concentrations.

ATMOSPHERIC PERSISTENCE

Toluene exists in the atmosphere in the gas phase, and the dominant tropospheric loss process is by reaction with the OH radical. The calculated half-life and lifetime of toluene due to reaction with the OH radical are 1.7 days and 2.4 days, respectively (Atkinson, 1995). The reaction products include benzaldehyde, benzyl nitrate, cresols, glyoxal, methylglyoxal, and poorly understood ring-opened

compounds (Atkinson, 1994).

AB 2588 RISK ASSESSMENT INFORMATION

The Office of Environmental Health Hazard Assessment reviews risk assessments submitted under the Air Toxics "Hot Spots" Program (AB 2588). Of the risk assessments reviewed as of December 1996, for non-cancer health effects, toluene contributed to the total hazard index in 51 of the approximately 89 risk assessments reporting a total chronic hazard index greater than 1. Toluene also contributed to a total hazard index greater than 1 in 7 of the approximately 107 risk assessments reporting a total acute hazard index greater than 1, and presented an individual hazard index greater than 1 in 1 of these risk assessments (OEHHA, 1996b).

HEALTH EFFECTS

The most probable route of human exposure to toluene is inhalation (HSDB, 1991).

Non-Cancer: Exposure to toluene may cause mild eye and respiratory tract irritation. The central nervous system (CNS) is the primary target organ for acute and chronic exposures. Toluene is a CNS depressant. Exposure may cause cardiac arrhythmias. Liver and kidney injury may occur with exposures to high concentrations. Long-term abuse by inhalation has caused CNS impairment (U.S. EPA, 1994a).

A chronic non-cancer Reference Exposure Level (REL) of 200 µg/m3 is listed for toluene in the California Air Pollution Control Officers Association Air Toxics "Hot Spots" Program, Revised 1992 Risk Assessment Guidelines. The toxicological endpoints considered for chronic toxicity are the central or peripheral nervous system, and the reproductive system including teratogenic and developmental effects (CAPCOA, 1993). The U.S. EPA has established a Reference Concentration (RfC) of 400 µg/m3 for toluene based on neurological effects in humans. The U.S. EPA estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic non-cancer effects. The U.S. EPA has established an oral Reference Dose of 0.2 milligrams per kilogram per day based on changes in liver and kidney weights in rats. The U.S. EPA estimates that consumption of this dose or less, over a lifetime, would not likely result in the occurrence of chronic, non-cancer effects.

Children of pregnant women exposed to toluene by inhalation have been reported to have developmental effects, such as CNS dysfunction, attention deficits, and minor craniofacial and limb anomalies; however, these studies were confounded by exposure to multiple chemicals. A number of case reports of toluene abuse via inhalation by pregnant women have also shown similar effects. Reproductive effects, including an association between paternal exposure to toluene and an increased odds ratio for spontaneous abortions but not birth defects, have also been noted. However, these studies are not conclusive due to many confounding variables. Several inhalation studies have shown toluene to be a developmental toxicant, but not a reproductive toxicant, in rodents (U.S. EPA, 1994a). The State of California under Proposition 65 has determined that toluene is a developmental toxicant (CCR, 1996).

Cancer: Two epidemiological studies did not detect a statistically significant increased risk of cancer due to inhalation exposure to toluene. However, these studies were limited due to the size of the study population and lack of historical monitoring data. The U.S. EPA has placed toluene in Group D: Not classifiable as a carcinogen (U.S. EPA, 1994a). The International Agency for Research on Cancer has

placed toluene in Group 3: Not classifiable as a carcinogen (IARC, 1989b).

Hazard Summary

CAUTION: Unless otherwise noted, the quantitative information on these fact sheets are from "EPA Health Effects Notebook for Hazardous Air Pollutants-Draft", EPA-452/D-95-00, PB95-503579, December 1994." Please conduct a current literature search and check the appropriate current online database for the most recent quantitative information.

- The central nervous system (CNS) is the primary target organ for toluene toxicity in both humans and animals for acute (short-term) and chronic (long-term) exposures. **CNS dysfunction** (which is often reversible) and **narcosis** have been frequently observed in humans acutely exposed to low or moderate levels of toluene by inhalation; symptoms include fatigue, sleepiness, headaches, and nausea. Cardiac arrhythmia has also been reported in humans acutely exposed to toluene.
- **CNS depression** has been reported to occur in chronic abusers exposed to high levels of toluene. Symptoms include ataxia, tremors, cerebral atrophy, nystagmus (involuntary eye movements), and impaired speech, hearing, and vision. Chronic inhalation exposure of humans to toluene also causes irritation of the upper respiratory tract, eye irritation, sore throats, nausea, skin conditions, dizziness, headaches, and difficulty with sleep.
- The Reference Concentration (RfC) for toluene is 0.4 mg/m^3.[a] The U.S. Environmental Protection Agency (EPA) estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic, noncancer effects.[b]
- The Reference Dose (RfD) for toluene is 0.2 mg/kg/d.[c] EPA estimates that consumption of this dose or less, over a lifetime, would not result in the occurrence of chronic, noncancer effects.
- Human studies have reported developmental effects, such as CNS dysfunction, attention deficits, and minor craniofacial and limb anomalies, in the children of pregnant women exposed to toluene or mixed solvents by inhalation. Reproductive effects, including an association between paternal exposure to toluene and an increased odds ratio for spontaneous abortions but not birth defects, have also been noted. However, these studies are not conclusive due to many confounding variables. Animal studies have shown toluene to have developmental, but not reproductive, effects from inhalation exposure.
- None of the data suggest that toluene is carcinogenic. Two epidemiological studies did not detect a statistically significant increased risk of cancer due to inhalation exposure to toluene. However,

these studies had many confounding factors. Animal studies have been negative for carcinogenicity. EPA has classified toluene as a Group D, **not classifiable as to human carcinogenicity**.

---

[a] Milligrams per cubic meter is the unit of measurement for chemicals in air.

[b] The RfC is not a direct estimator of risk but rather a reference point to gauge the potential effects. Exceedance of the RfC does not imply that an adverse health effect would necessarily occur. As the amount and frequency of exposures exceeding the RfC increase, the probability of adverse health effects also increases.

[c] Milligrams per kilogram per day is one way to measure the amount of the contaminant that is consumed in food.

Please Note: The main sources of information for this fact sheet are EPA's Integrated Risk Information System (IRIS), which contains information on inhalation chronic toxicity of toluene and the RfC, oral chronic toxicity and the RfD, and the carcinogenic effects of toluene, and the Agency for Toxic Substances and Disease Registry's (ATSDR's) *Toxicological Profile for Toluene*. Other secondary sources include the Hazardous Substances Data Bank (HSDS), a database of summaries of peer-reviewed literature, and the Registry of Toxic Effects of Chemical Substances (RTECS), a database of toxic effects that are not peer reviewed.

Environmental/Occupational Exposure

- The highest concentrations of toluene usually occur in indoor air from the use of common household products (paints, paint thinners, and adhesives) and cigarette smoke. The deliberate inhalation of paint or glue may produce high levels of exposure to toluene, as well as to other chemicals, in solvent abusers. (1)
- Toluene exposure may also occur in the workplace, especially in occupations such as printing or painting, where toluene is frequently used as a solvent. (1)
- Automobile emissions are the principal source of toluene to the ambient air. Toluene may also be released to the ambient air during the production, use, and disposal of industrial and consumer products that contain toluene. (1)

Assessing Personal Exposure

- Toluene and its breakdown products can be detected in the blood or urine to determine whether or not exposure has occurred. Metabolites measured in the urine are not specific to toluene, and testing must occur within 12 hours of exposure. (1)

Health Hazard Information

Acute Effects:

- The central nervous system is the primary target organ for toluene toxicity in both humans and animals for acute (short-term) and chronic (long-term) exposures. CNS dysfunction (which is often reversible) and narcosis have been frequently observed in humans acutely exposed to low or moderate levels of toluene by inhalation; symptoms include fatigue, sleepiness, headaches, and

nausea. CNS depression and death have occurred at higher levels of exposure. (1)

- Cardiac arrhythmia has also been reported in humans acutely exposed to toluene. (1)
- Following the ingestion of toluene a person died from a severe depression of the central nervous system. Constriction and necrosis of myocardial fibers, swollen liver, congestion and hemorrhage of the lungs, and tubular kidney necrosis were also reported. (1)
- Acute exposure of animals to toluene has been reported to affect the central nervous system as well as to decrease resistance to respiratory infection. (1)
- Acute animal tests, such as the LC_{50} and LD_{50} tests in rats and mice, have demonstrated toluene to have low acute toxicity by inhalation or oral exposure. (1)

Chronic Effects (Noncancer):

- CNS depression has been reported to occur in chronic (long-term) abusers exposed to high levels of toluene. Symptoms include ataxia, tremors, cerebral atrophy, nystagmus (involuntary eye movements), and impaired speech, hearing, and vision. (1,2)
- Effects on the central nervous system have also been observed in studies of animals chronically exposed by inhalation. (1,2)
- Chronic inhalation exposure of humans to toluene causes irritation of the upper respiratory tract, eye irritation, sore throats, nausea, skin conditions, dizziness, headaches, and difficulty with sleep. (1,2)
- Inflammation and degeneration of the nasal and respiratory epithelium and pulmonary lesions have been observed in rats and mice chronically exposed to high levels of toluene by inhalation. (1)
- Mild effects on the kidneys and liver have been reported in solvent abusers chronically exposed to toluene vapor. However, these studies are confounded by probable exposure to multiple solvents. (1,2)
- Slight adverse effects on the liver, kidneys, and lung have been reported in some chronic inhalation studies of rodents. (1)
- The RfC for toluene is 0.4 mg/m^3 based on neurological effects in humans. (2)
- EPA has medium confidence in the study on which the RfC was based because it indicates adverse neurological effects of toluene in a small worker population; medium confidence in the database because even though many chronic laboratory animal studies are available, long-term data in humans are not available for either the neurotoxicity or irritation endpoint; and, consequently, medium confidence in the RfC. (2)
- The RfD for toluene is 0.2 mg/kg/d based on changes in liver and kidney weights in rats. (2)
- EPA has high confidence in the study on which the RfD was based because a sufficient number of animals/sex were tested in each of six dose groups and many parameters were studied; medium confidence in the database because it is supported by a 6-month oral study; and, consequently, medium confidence in the RfD. (2)
- EPA's Office of Air Quality Planning and Standards, for a hazard ranking under Section 112(g) of the Clean Air Act Amendments, has evaluated toluene for chronic toxicity and has given it a composite score of 7 (scores range from 1 to 100, with 100 being the most toxic). These scores are nonlinear and are the product of two ratings: a rating based on the minimal-effect-dose and a rating based on the type of effect. (3)

Reproductive/Developmental Effects:

- CNS dysfunction, attention deficits, minor craniofacial and limb anomalies, and developmental delay were observed in the children of pregnant women exposed to toluene or to mixed solvents by inhalation. Growth retardation and dysmorphism were reported in infants of another study. However, these studies were confounded by exposure to multiple chemicals. (1,2)
- Children born to toluene abusers have exhibited temporary renal tubular acidosis. (1)
- Paternal exposure (in which the mothers had no occupational exposure to toluene but the fathers did) increased the odds ratio for spontaneous abortions but not congenital malformations. However, these observations cannot be clearly ascribed to toluene because of the small number of cases evaluated and the large number of confounding variables. (1)
- Several inhalation studies have shown toluene to be a developmental toxicant, but not a reproductive toxicant, in rodents. (1)

Cancer Risk:

- Two epidemiological studies did not detect a statistically significant increased risk of cancer due to inhalation exposure to toluene. However, these studies were limited due to the size of the study population and lack of historical monitoring data. (1)
- Inhalation exposure of rats did not produce an increased incidence of treatment-related neoplastic lesions. (1,2)
- EPA has classified toluene as a Group D, not classifiable as to human carcinogenicity. (2)

Physical Properties

- The chemical formula for toluene is $C_6H_5CH_3$, and its molecular weight is 92.15 g/mol. (1,4)
- Toluene occurs as a colorless, flammable, refractive liquid, that is slightly soluble in water. (1,5)
- Toluene has a sweet, pungent odor, with an odor threshold of 2.9 ppm. (1,6)
- The vapor pressure for toluene is 22 mm Hg at 20 C, and its log octanol/water partition coefficient (log K_{ow}) is 2.79. (1)

Uses

- The major use of toluene is as a mixture added to gasoline to improve octane ratings. Toluene is also used to produce benzene and as a solvent in paints, coatings, adhesives, inks, and cleaning agents. (1)
- Toluene is also used in the production of polymers used to make nylon, plastic soda bottles, and polyurethanes and for pharmaceuticals, dyes, cosmetic nail products, and the synthesis of organic chemicals. (1)

Conversion Factors:

To convert from ppm to mg/m^3: mg/m^3 = (ppm) × (molecular weight of the compound)/(24.45). For toluene: 1 ppm = 3.77 mg/m^3.

Health Data from Inhalation Exposure

Concentration (mg/m^3)	Health numbers[a]	Regulatory, advisory numbers[b]	Reference
100,000.0			
-- -- -- -- 10,000.0	• LC_{50} (rats) ($33,176\ mg/m^3$) • LC_{50} (mice) ($20,056\ mg/m^3$)		1 1
-- -- -- -- 1,000.0			
-- -- -- -- 100.0	• LOAEL (humans) ($332\ mg/m^3$)	• ACGIH TLV, NIOSH REL, OSHA PEL, MSHA ($75\ mg/m^3$)	2 7
-- -- -- -- 10.0			
-- -- -- -- 1.0			
-- -- -- -- 0.1	• RfC ($0.4\ mg/m^3$)		2

ACGIH TLV--American Conference of Governmental and Industrial Hygienists' threshold limit value expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effects.
LC_{50} (Lethal $Concentration_{50}$)--A calculated concentration of a chemical in air to which exposure for a specific length of time is expected to cause death in 50% of a defined experimental animal population.
LOAEL--Lowest-observed-adverse-effect level.
MSHA--Mine Safety and Health Administration.

NIOSH REL--National Institute of Occupational Safety and Health's recommended exposure limit; NIOSH-recommended exposure limit for an 8- or 10-h time-weighted-average exposure and/or ceiling.
OSHA PEL--Occupational Safety and Health Administration's permissible exposure limit expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effect averaged over a normal 8-h workday or a 40-h workweek.
RfC--Reference concentration.

[a] Health numbers are toxicological numbers from animal testing or risk assessment values developed by EPA.
[b] Regulatory numbers are values that have been incorporated in Government regulations, while advisory numbers are nonregulatory values provided by the Government or other groups as advice.

Toluene; CASRN 108-88-3

Health assessment information on a chemical substance is included in IRIS only after a comprehensive review of chronic toxicity data by U.S. EPA health scientists from several Program Offices and the Office of Research and Development. The summaries presented in Sections I and II represent a consensus reached in the review process. Background information and explanations of the methods used to derive the values given in IRIS are provided in the Background Documents.

__I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

Substance Name -- Toluene
CASRN -- 108-88-3
Last Revised -- 04/01/1994

The oral Reference Dose (RfD) is based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. It is expressed in units of mg/kg-day. In general, the RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Please refer to the Background Document for an elaboration of these concepts. RfDs can also be derived for the noncarcinogenic health effects of substances that are also carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.A.1. ORAL RfD SUMMARY

Critical Effect	Experimental Doses*	UF	MF	RfD
Changes in liver and kidney weights 13-Week Rat Gavage Study NTP, 1989	NOAEL: 312 mg/kg converted to 223 mg/kg/day LOAEL: 625 mg/kg converted to 446 mg/kg/day	1000	1	2E-1 mg/kg/day

*Conversion Factors: Dose adjusted for gavage schedule of 5 days/week.

I.A.2. PRINCIPAL AND SUPPORTING STUDIES (ORAL RfD)

NTP (National Toxicology Program). 1989. Toxicology and Carcinogenesis Studies of toluene in F344/N rats and B6C3F1 mice. Technical Report Series No. 371. Research Triangle Park, NC.

The oral toxicity of toluene was investigated in this subchronic gavage study in F344 rats. Groups of 10 rats/sex/group were administered toluene in corn oil at dosage levels of 0, 312, 625, 1250, 2500, or 5000 mg/kg for 5 days/week for 13 weeks. All animals receiving 5000 mg/kg died within the first week. One female and 8 males in the 2500 mg/kg group died, but 2 of these were due to gavage errors. No deaths occurred at lower doses. Several toxic effects were noted at doses greater than or equal to 2500 mg/kg, including prostration, hypoactivity, ataxia, piloerection, lacrimation, excessive salivation, and body tremors. No signs of biologic significance were seen in groups receiving less than or equal to 1250 mg/kg. The only significant change in body weight was a decrease ($p<0.05$) for males in the 2500 mg/kg group. There were no toxicologically significant changes in hematology or urinalysis for any group of animals. Biochemical changes, including a significant increase ($p<0.05$) in SGOT in 2500 males and a dose-related increase in cholinesterase in females receiving 2500 and 5000 mg/kg, were not considered to be biologically significant. There were several pathologic findings and organ weight changes in the liver, kidney, brain, and urinary bladder. In males, absolute and relative weights of both the liver and kidney were significantly increased ($p<0.05$) at doses greater than or equal to 625 mg/kg. In females, absolute and relative weights of the liver, kidney, and heart were all significantly increased at doses greater than or equal to 1250 mg/kg ($p<0.01$ for all comparisons except $p<0.05$ for absolute kidney and heart weights at 1250 mg/kg). Histopathologic lesions in the liver consisted of hepatocellular hypertrophy, occurring at greater than or equal to 2500 mg/kg. Nephrosis was observed in rats that died, and damage to the tubular epithelia of the kidney occurred in terminally sacrificed rats. Histopathologic changes were also noted in the brain and urinary bladder. In the brain, mineralized foci and necrosis of neuronal cells were observed in males and females at 2500 mg/kg and males at 1250 mg/kg. In the bladder, hemorrhage of the muscularis was seen in males and females at 5000 mg/kg and males at 2500 mg/kg. The NOAEL for this study is 312 mg/kg/day based on liver and kidney weight changes in male rats at 625 mg/kg. The toxicologic significance of these organ weight changes is strengthened by the occurrence of histopathologic changes in both the liver and kidney at higher doses. Because the exposure was for 5 days/week, this dose is converted to 312 x 5/7 = 223 mg/kg/day. The LOAEL is 625 mg/kg, which is 446 mg/kg/day when converted.

NTP (1989) also conducted a 13-week gavage study in B6C3F1 mice, following the same regimen described above. All mice receiving 5000 mg/kg died and 8/20 receiving 2500 mg/kg also died. Signs of toxicity seen in animals receiving greater than or equal to 2500 mg/kg included subconvulsive jerking, prostration, impaired grasping reflex, bradypnea, hypothermia, ataxia, and hypoactivity. By week 13, the mean body weight of 2500 mg/kg males was significantly ($p<0.05$) lower than controls. No other significant changes were reported for any group, including macroscopic observation, organ weight means,

or clinical pathology parameters. The NOAEL for mice in this study was 1250 mg/kg.

The subchronic study by Wolf et al. (1956) is supportive of the NTP studies. Groups of 10 female Wistar rats were administered gavage doses of 0, 118, 354, or 590 mg/kg toluene dissolved in olive oil. A total of 138 doses were administered over 193 days, resulting in average doses of approximately 0, 84, 253, or 422 mg/kg/day. Hematologic, behavioral, gross and histopathologic examinations were conducted with no toxic effects being reported at any dose. Therefore, the highest dose of 422 mg/kg/day is considered to be the NOAEL for this study. However, this study is not used as the basis for the RfD because the LOAEL of 446 mg/kg/day identified by NTP (1989) is too close to the NOAEL identified by Wolf et al. (1956). Also, the NTP study indicated that male rats are more sensitive to toluene and the Wolf study utilized only female rats.

___I.A.3. UNCERTAINTY AND MODIFYING FACTORS (ORAL RfD)

UF -- An uncertainty factor of 1000 was applied to account for inter- and intraspecies extrapolations, for subchronic-to-chronic extrapolation and for limited reproductive and developmental toxicity data.

MF -- None

___I.A.4. ADDITIONAL COMMENTS (ORAL RfD)

Kostas and Hotchin (1981) exposed NYLAR mice pre- and post-natally to toluene provided in the drinking water at concentrations of 0, 16, 80, or 400 ppm. Effects were noted in all dosed groups on rotorod performance, measured at 45 to 55 days of age, but there was an inverse dose-response relationship. No effects of toluene exposure were seen on maternal fluid consumption, offspring mortality rate, development of eye or ear openings, or surface-righting response. This study is not suitable for use in risk assessment because only 6 to 9 pregnancies/dose group were obtained, and because the dose-response relationship was inverse.

In an abstract providing limited information, Nawrot and Staples (1979) reported an increase in embryonic lethality in mice exposed to toluene from days 6 to 15 of gestation. Pregnant CD-1 dams were administered 0.3, 0.5, or 1.0 mL/kg bw, 3 times/day (equivalent to approximately 780, 1300, or 2600 mg/kg/day). Maternal toxicity was not observed at any dose level, but toluene was shown to be teratogenic at the high dose and embryolethal at the low dose. These levels are higher than the NOAEL demonstrated by the NTP (1989) study.

Several subchronic and chronic inhalation studies have been performed on toluene but are not considered to be suitable for deriving an oral RfD. These

studies are summarized nicely in the introduction to the 2-year inhalation bioassay by NTP, 1989. The studies identify the following potential target organs: kidney (male rat); hematologic effects (mice); central nervous system (rats, mice, primates); developmental toxicity (rats, rabbits). It is beyond the scope of this oral RfD summary sheet to describe each of these studies, but the two chronic (2 year) inhalation studies are summarized briefly below.

In a 2-year inhalation study by NTP (1989), F344 rats (60/sex/group) were exposed to 0, 600, or 1200 ppm toluene and B6C3F1 mice (60/sex/group) to 0, 120, 600, or 1200 ppm toluene for 6.5 hours/day, 5 days/week. Ten animals/group (except male mice) were removed at 15 months for toxicologic evaluation. At 15 months, there was an increased incidence and severity of nonneoplastic lesions of the nasal cavity of exposed rats. Minimal hyperplasia of the bronchial epithelium was seen in 4/10 female mice at 1200 ppm. There were no significant differences in survival among any group of animals during the 2-year study. Mean body weights were generally similar for all groups throughout the study. Nephropathy was seen in almost all rats with the severity somewhat increased in exposed rats. There were also effects on the olfactory and respiratory epithelia of exposed rats. No biologically important lesions were seen in any groups of mice. There was no evidence of carcinogenicity for any group of animals in this study.

A chronic inhalation study in rats performed by CIIT (1980) failed to produce an adverse effect. Groups of 40 F344 rats/sex were exposed to 30, 100, or 300 ppm toluene for 6 hours/day, 5 days/week for 24 months. An unexposed group of 120 rats/sex served as a control. Clinical chemistry, hematology, and urinalysis testing were conducted at 18 and 24 months. All parameters measured at the termination of the study were normal except for a dose-related reduction in hematocrit values in females exposed to 100 and 300 ppm toluene. The highest dose of 300 ppm was considered to be a NOAEL.

___I.A.5. CONFIDENCE IN THE ORAL RfD

Study: High
Data Base: Medium
RfD: Medium

Confidence in the principal study is high because a sufficient number of animals/sex were tested in each of six dose groups (including vehicle controls) and many parameters were studied. The same protocol was tested in both mice and rats, with rats being identified as the more sensitive species. The data base is rated medium because it is supported by a 6-month oral study. It is not higher than medium because there is no reproductive study. Also, the oral studies are all subchronic, with the critical study being only 13 weeks in duration. Medium confidence in the RfD follows.

___I.A.6. EPA DOCUMENTATION AND REVIEW OF THE ORAL RfD

Source Document -- This assessment is not presented in any existing U.S. EPA document.

Other EPA Documentation -- None

Agency Work Group Review -- 05/20/1985, 08/05/1985, 08/05/1986, 05/17/1990, 06/20/1990

Verification Date -- 06/20/1990

___I.A.7. EPA CONTACTS (ORAL RfD)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

__I.B. REFERENCE CONCENTRATION FOR CHRONIC INHALATION EXPOSURE (RfC)

Substance Name -- Toluene
CASRN -- 108-88-3
Last Revised -- 08/01/1992

The inhalation Reference Concentration (RfC) is analogous to the oral RfD and is likewise based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. The inhalation RfC considers toxic effects for both the respiratory system (portal-of-entry) and for effects peripheral to the respiratory system (extrarespiratory effects). It is expressed in units of mg/cu.m. In general, the RfC is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily inhalation exposure of the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Inhalation RfCs were derived according to the Interim Methods for Development of Inhalation Reference Doses (EPA/600/8-88/066F August 1989) and subsequently, according to Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994). RfCs can also be derived for the noncarcinogenic health effects of substances that are carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA

has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.B.1. INHALATION RfC SUMMARY

Critical Effect	Exposures*	UF	MF	RfC
Neurological effects	NOAEL: None	300	1	4E-1 mg/cu.m
Occupational Study Foo et al., 1990	LOAEL: 332 mg/cu.m (88 ppm) LOAEL(ADJ): 119 mg/cu.m LOAEL(HEC): 119 mg/cu.m			
Degeneration of nasal epithelium 2-Year Rat Chronic Inhalation Study NTP, 1990	NOAEL: None LOAEL: 2261 mg/cu.m (600 ppm) LOAEL(ADJ): 437 mg/cu.m LOAEL(HEC): 79 mg/cu.m			

*Conversion Factors: MW = 92.15.

Foo et al., 1990: Assuming 25 C and 760 mmHg, LOAEL (mg/cu.m) = 88 ppm x 92.15/24.45 = 332 mg/cu.m. This is an extrarespiratory effect of a soluble vapor. The LOAEL is based on an 8-hour TWA occupational exposure. MVho = 10 cu.m/day, MVh = 20 cu.m/day. LOAEL(HEC) = LOAEL(ADJ) = 332 x MVho/MVh x 5 days/7 days = 119 mg/cu.m.

NTP, 1990: Assuming 25 C and 760 mmHg, LOAEL (mg/cu.m) = 600 ppm x 92.15/24.45 = 2261 mg/cu.m. LOAEL(ADJ) = LOAEL (mg/cu.m) x 6.5 hours/24 hours x 5 days/7 days = 437 mg/cu.m. The LOAEL(HEC) was calculated for a gas:respiratory effect in the extrathoracic region. MVa = 0.24 cu.m/day, MVh = 20 cu.m/day, Sa (ET) = 11.6 sq.cm, Sh (ET) = 177 sq.cm. RGDR = (MVa/Sa) / (MVh/Sh) = 0.18. LOAEL(HEC) = 437 x RGDR = 79 mg/cu.m.

___I.B.2. PRINCIPAL AND SUPPORTING STUDIES (INHALATION RfC)

Foo, S., J. Jeyaratnam and D. Koh. 1990. Chronic neurobehavioral effects of toluene. Br. J. Ind. Med. 47(7): 480-484.

NTP (National Toxicology Program). 1990. Toxicology and carcinogenesis studies of toluene in F344/N rats and B6C3F1 mice (inhalation studies). NTP-TR-371. 253 p.

In humans, toluene is a known respiratory irritant with central nervous

system (CNS) effects. Because available studies could not provide subthreshold (NOAEL) concentrations for either of these effects, the LOAELs for both effects need to be considered in developing the RfC. Consequently, the study of Foo et al. (1990) was used for the CNS effects, and that of the National Toxicology Program (NTP, 1990) for the irritant effects. Because the CNS effect was judged to be a more severe and relevant endpoint, the LOAEL for this effect was used for deriving the RfC. Further, this effect is supported by a number of other occupational studies that show effects around 100 ppm.

Foo et al. (1990) conducted a cross-sectional study involving 30 exposed female workers employed at an electronic assembly plant where toluene was emitted from glue. Toluene levels reported in the study were from personal sample monitoring and reported as an 8-hour TWA, although the number of samples taken and the actual sampling period were not given. No historical exposure values were given. Co-exposure to other solvents was not addressed in the study. The exposed and control cohorts were matched for age, ethnicity, and use of medications. Members of these cohorts did not use alcohol and were nonsmokers. Medical histories were taken to eliminate any histories of central or peripheral nervous system disorders. The average number of years (+/- SD) worked by the exposed population was 5.7 +/- 3.2 and by the controls was 2.5 +/- 2.7. Exposed workers breathed toluene air levels of 88 ppm (332 mg/cu.m) as a TWA and control workers 13 ppm (49 mg/cu.m) (TWA); both of which are averages of the individual personal samples. A battery of eight neurobehavioral tests were administered to all exposed and control workers. The tests were performed midweek, before the workers reported to their stations for the day. Group means revealed statistically significant differences in 6/8 tests; all tests showed that the exposed workers performed poorly compared with the control cohort. When individual test results were linearly regressed against personal exposure concentrations, poor concentration-response relationships resulted for the six tests, with correlation coefficients ranging from 0.44 to 0.30. Irritation effects were not evaluated in this study, and no clinical signs or symptoms were reported. The paucity of exposure information, coupled with the small size of the cohort, limits the interpretation of this study, although the results were essentially confirmed in a clinical study in which the toluene concentrations were carefully controlled (Echeverria et al., 1989) at levels bracketing 88 ppm. Although the data in Echeverria et al. (1989) were generated from short-term exposures (3-7 hours over a period of 142 days), the results may be considered relevant to longer-term exposures as several studies indicate the absence of a duration-response relationship in toluene-induced symptomatology. Fornazzari et al. (1983) noted the absence of a duration-effect relationship among toluene abusers when they were segregated into neurologically impaired vs. unimpaired ($p = 0.65$). The human studies of Iregren (1982), Cherry et al. (1985), Baelum et al. (1985), and the principal study of Foo et al. (1990) all report this lack of a duration-response relationship and confirm the occurrence of CNS effects. Foo et al. (1990) indicate a LOAEL of 88 ppm toluene (332 mg/cu.m) for neurobehavioral changes from chronic exposure to toluene.

In a 2-year bioassay, Fischer 344 rats (60/sex/group) were exposed to 0, 600, or 1200 ppm (0, 2261, or 4523 mg/cu.m, respectively) toluene vapors, 6.5 hours/day, 5 days/week (duration-adjusted to 0, 437, and 875 mg/cu.m, respectively) for 103 weeks (NTP, 1990). To generate toluene vapor, the liquid material was heated, and the vapor diluted with nitrogen and mixed with the chamber ventilation air. An interim sacrifice was carried out at 15

months on control and 1200-ppm groups (10/sex/group) to conduct hematology and histopathology of the brain, liver, and kidney. Body weights were measured throughout the study. Gross necropsy and micropathology examinations were performed at the end of the study on all major organs including the nasal passage tissues (three sections), lungs, and mainstem bronchi. Mean body weights in both exposed groups were not different from controls for either sex. No exposure-related clinical signs were reported, and survival rate was similar for all groups. At the interim sacrifice, there was a mild-to-moderate degeneration in the olfactory and respiratory epithelium of the nasal cavity in 39/40 rats of the 600- and 1200-ppm groups compared with 7/20 controls. At the end of 2 years, there was a significant ($p<0.05$) increase in the incidence of erosion of the olfactory epithelium (males: 0/50, 3/50, and 8/49; females: 2/49, 11/50, and 10/50; at 0, 600, and 1200 ppm, respectively) and of degeneration of the respiratory epithelium (males: 15/50, 37/50, and 31/49; females: 29/49, 45/50, and 39/50; at 0, 600, and 1200 ppm, respectively) in the exposed animals. The females exposed to 600 and 1200 ppm also exhibited a significant increase in inflammation of the nasal mucosa (27/49, 42/50, and 41/50 at 0, 600, and 1200 ppm, respectively) and respiratory metaplasia of the olfactory epithelium (0/49, 2/50, and 6/50 at 0, 600, and 1200 ppm, respectively). A LOAEL of 600 ppm toluene was determined for the concentration-dependent increase in erosion of the olfactory epithelium in male rats and the degeneration of the respiratory epithelium in both sexes. No NOAEL could be derived from this study.

___I.B.3. UNCERTAINTY AND MODIFYING FACTORS (INHALATION RfC)

UF -- An uncertainty factor of 10 is used to account for intraspecies variability and another factor of 10 for the use of a LOAEL. An additional factor of 3 is applied for data base deficiencies, including the lack of data and well-characterized laboratory animal exposures evaluating neurotoxicity and respiratory irritation.

MF -- None

___I.B.4. ADDITIONAL STUDIES / COMMENTS (INHALATION RfC)

Toluene-induced neurotoxicity has been documented in humans over a broad spectrum of severity that correlates well with concentration. Numerous case studies on chronic toluene abusers [repeatedly exposed to greater than 30,000 ppm (113,000 mg/cu.m)] have demonstrated functional deficits of the CNS accompanied by abnormal morphology of cerebellar and cortical areas of the brain. Under acute exposure conditions [short exposures to greater than 10,000 ppm (37,690 mg/cu.m)], toluene produces CNS narcosis [American Conference of Governmental Industrial Hygienists (ACGIH), 1991]. Lower concentrations, i.e., 800-400 ppm (3015-1508 mg/cu.m), have been associated with worker complaints of CNS-related effects (ACGIH, 1991). Clinical studies

using controlled exposure to toluene have demonstrated concentration-related occurrence of complaints such as drowsiness, ataxia, visual impairment, and headache. A number of occupational studies indicate that these same effects are present in exposed worker populations at concentrations lower than 400 ppm (1508 mg/cu.m) although deficiencies in most of these studies preclude confirming this finding unequivocally. Descriptions of a number of these studies follow. The preponderence of the literature showing CNS effects and the well-known proclivity for solvents to affect CNS processes in humans leave little doubt that the brain is a principal target organ for toluene toxicity in humans.

In cases of inhalation abuse of toluene, Rosenberg et al. (1988) demonstrated diffuse cerebral, cerebellar, and brainstem atrophy in 3 of 11 toluene abusers who also had neurological abnormalities. Filley et al. (1990) were able to correlate neuropsychological impairment with the degree of white matter abnormality ($p<0.01$). Cerebellar and cortical functions were classified as impaired in 15/24 individuals who had abused toluene daily (425 +/- 366 mg/day) for extended periods (6.3 +/- 3.9 years) (Fornazzari et al., 1983). In a limited case study, Metrick and Brenner (1982) demonstrated brainstem atrophy through computerized tomographic scans and abnormal brainstem auditory-evoked potentials in 2/2 chronic toluene abusers (12-16 years of admitted, continuous abuse). These studies confirm the occurrence of severe CNS damage in response to highly abusive concentrations of toluene.

Several studies that have investigated the occurrence of neurotoxicity at lesser concentrations, such as occupational situations, have not demonstrated significant neurological or other effects. Hanninen et al. (1987) performed a battery of 11 psychological tests on 43 printing workers who had been occupationally exposed to approximately 117 ppm (441 mg/cu.m) toluene for an average of 22 years and found only mildly adverse effects in 2/11 tests. The control and exposed cohorts in this study were, however, mismatched in several areas, most notably alcohol use. Iregren (1982) examined the psychological performance of 38 printers who had been occupationally exposed to 50-150 ppm (188-565 mg/cu.m) toluene for an average of 16.3 years (range 3-32 years). No effects were seen, although the cohorts in this study were apparently matched only by age. In a cohort study, Cherry et al. (1985) attempted to better match the control and exposed cohorts and considered alcohol use. Although no differences between the cohorts were statistically significant, the exposed workers performed worse than the nonexposed workers on 10/13 psychological tests. The 52 workers in this study were not, however, rigorously matched, and the concentrations listed in the study ranged up to greater than 500 ppm (1884 mg/cu.m). The cohorts in the study of Foo et al. (1990) were well matched for a number of confounders, including alcohol use, and statistically significant psychological effects were seen.

In the occupational study conducted by Yin et al. (1987), 94 solvent workers (38 men and 56 women; average employment duration, 6.8 years) and 138 controls (48 men and 90 women) were examined for exposure using diffusion dosimeters, subjective symptoms by questionnaire, hematology, and urinalysis. Exposure concentration (7-hour mean TWA) in the workers was estimated at 42.8 ppm (161 mg/cu.m) toluene with a maximum measurement of 123 ppm (464 mg/cu.m). Workers were co-exposed to 1.3 ppm benzene. No exposure-related effects were noted in any of the biochemical tests examined. In considering the prevalence of subjective symptoms (sore throat, headaches, and dizziness) workers were subgrouped into low (6-39 ppm, n = 28) and high (40-123 ppm, n = 29)

categories. Although the prevalence of subjective symptoms was significantly higher in the exposed workers compared with the control cohort ($p<0.01$), a concentration-response relationship was not discernable among the groups. No other treatment-related effects were reported. The study was limited because the exposed and unexposed groups were not matched to control for confounding effects (e.g., age, smoking, alcohol consumption, exposure duration). Based on these results, exposure to an average of approximately 42.8 ppm toluene produced no biochemical abnormalities, although neither respiratory irritation nor psychological performance was directly evaluated in these workers.

In the occupational study by Lee et al. (1988), prevalence of subjective symptoms was categorized with respect to exposure levels. The study population (193 women and 65 controls) completed a questionnaire. The exposures were reported as 8-hour TWAs, and workers were grouped in exposure categories of nonexposed, 1-50 ppm, 51-100 ppm, 101-150 ppm, and more than 151 ppm (duration of exposures was not reported). A concentration-dependent increase in prevalence was reported for 25/67 symptoms with increases in complaints over controls occurring at around 100 ppm (348 mg/cu.m). Similar to the Yin et al. study (1987) reported above, symptomatology included headaches, sore throats, and dizziness. Although an effect level in humans of around 100 ppm is indicated by this study, no objective measures of toxicity were examined.

A number of acute human studies have focused on toluene effects. In general, these studies corroborate subjective CNS effects such as headaches and dizziness reported in other longer-term occupational studies (Yin et al., 1987; Lee et al., 1988) and also document irritation effects. The study of Echeverria et al. (1989) correlates the occurrence of these subjective effects with substantial neurological symptoms.

Forty-two college students (21 female and 21 male) were exposed to 0, 74 ppm (279 mg/cu.m), or 151 ppm (569 mg/cu.m) toluene for 7 hours over 3 days (Echeverria et al., 1989). This exposure sequence was repeated for a total of 42 exposures over a 3-month period. The odor of toluene was masked. A battery of performance tests was administered to each participant prior to starting the exposures and again at 4 and 7 hours during the exposure; the initial test served as a control for those tests performed during the exposure. A 5-10% decrement in performance was considered significant if consistent with a linear trend. Test results for visual perception differed from control values for both exposure levels. Results of a manual dexterity test differed from control values at the higher but not the lower exposure level. Psychomotor test results were unaffected by toluene exposure. Subjective symptomatology increased with exposure with increasing numbers of complaints of eye irritation, headache, and somnolence. A NOAEL of 74 ppm (279 mg/cu.m) is indicated for these results. The duration-adjusted value is 122 mg/cu.m for these acute effects.

Andersen et al. (1983) exposed 16 subjects (average age of 24 years) to 0, 10, 40, or 100 ppm (0, 38, 151, or 377 mg/cu.m) toluene for 6 hours on each of 4 consecutive days. Individuals were tested for nasal mucous flow, lung function, subjective response, and psychometric performance. At 100 ppm, irritation was experienced in the eyes and nose, but no effect on nasal mucous flow or lung function was observed. The subjects frequently reported headaches, dizziness, and a feeling of intoxication. These effects were not reported by the 10- or 40-ppm exposure groups. No effects were seen in

performance tests. This study indicates an effect level of 100 ppm, and a NOAEL of 40 ppm (151 mg/cu.m).

The acute study by Baelum et al. (1990) evaluated 32 males and 39 females exposed to 0 or 100 ppm (0 or 377 mg/cu.m), or to varying exposures of 50-300 ppm (188-1131 mg/cu.m) (TWA = 102 ppm), for 7 hours. Volunteers exercised on an ergometer cycle for 3 periods of 15 minutes each during the exposure. No significant differences were found in the performances between the exposed and control groups in a battery of tests for performance, visual attention, and reaction times. Exposed subjects reported an increase over nonexposed subjects ($p<0.1$) in nose and lower respiratory irritation, feelings of intoxication, dizziness, increased coughing, and headaches. Differences were not noted between the group exposed to a constant level (100 ppm) and the group exposed to the same TWA, but with peaks of up to 300 ppm.

Baelum et al. (1985) investigated the effects of a 6.5-hour toluene exposure to 43 printers with a long-term occupational exposure to a mixture of solvents including toluene and 43 controls with no history of exposure to solvents or other chemicals. The duration of employment for the workers ranged from 9-25 years. Each individual was exposed only once to either 0 or 100 ppm (0 or 377 mg/cu.m) toluene during a 6.5-hour exposure period, preceded by a 1-hour acclimatization period. These subjects were then subgrouped into printers exposed to toluene (n = 20), printers exposed to air (n = 23), controls exposed to toluene (n = 21), and controls exposed to air (n = 22). All subjects carried out a battery of tests for psychometric performance, visual perception, and vigilance evaluation. Both printers and controls complained of nasal and eye irritation, unacceptable air quality, and unacceptable odor level during the toluene exposure. Signs of neurotoxicity, including moderate fatigue, sleepiness, headaches, and a feeling of intoxication, were likewise similarly reported for both groups. A significant decrease in performance was found for the pegboard visual motor function test in the exposed printers, but not in the controls exposed to 100 ppm toluene. A decrease in psychometric performance, primarily in visual perception and accuracy, was observed in toluene-exposed individuals. Acute exposure to toluene resulted in a lower performance in 4/10 tests conducted, 3 of these 4 evaluated visual perception. The most profound difference between subjects exposed to 100 ppm toluene and those exposed to clean air was observed in the color discrimination test; this difference was seen in both exposed vs. nonexposed printers and exposed vs. nonexposed controls. This study indicates that little tolerance develops to the irritative and central effects in humans exposed to toluene and that 100 ppm (377 mg/cu.m) is the effect level for these symptoms.

Von Oettingen et al. (1942) exposed 3 humans to 100 or 200 ppm (377 or 754 mg/cu.m) toluene vapors for 8 hours. At 200 ppm, the subjects experienced muscular weakness, confusion, impaired coordination, and dilated pupils, with after-effects including fatigue, general confusion, and moderate insomnia. In 1 subject exposed to 100 ppm toluene, moderate fatigue, sleepiness, and headaches were reported.

Hepatotoxicity has also been examined as a toxicologic endpoint of toluene exposure in humans. Fornazzari et al. (1983) described moderate elevation of serum AP levels in 13/24 (and SGOT in 7/24) toluene abusers upon admission to a clinic. These elevated levels were normal after 2 weeks of solvent abstinence, although the accompanying CNS effects were only minimally

improved. In a cross-sectional study of 181 printing workers in which toluene exposures were less than 200 mg/cu.m, no adverse effects were apparent as judged from serum liver enzymes (Boewer et al., 1988). In another cross-sectional occupational study conducted by Guzelian et al. (1988) that involved 289 printing factory employees, 8 workers were found who had an increase described as "marked" in the ratio of ALT/AST enzyme serum activity. Biopsies revealed mild pericentral fatty livers in each of the eight cases. Based on environmental data (probably area monitors) the levels of toluene to which these workers were exposed was less than 200 mg/cu.m., 2-8 hours/day.

Fischer 344 rats (120/sex/group) inhaled 0, 30, 100, or 300 ppm (0, 113, 377, or 1130 mg/cu.m, respectively) toluene (99.9% purity), 6 hours/day, 5 days/week (duration-adjusted to 0, 20, 67, or 202 mg/cu.m, respectively) for 106 weeks (CIIT, 1980; Gibson and Hardisty, 1983). Vapor, generated by bubbling clean air through toluene, was passed through the air supply duct and mixed with air by turbulent flow to produce the desired concentration. Hematology, blood chemistry, and urinalysis were conducted in all groups at 6 (5/sex), 17 (5/sex), 18 (10-20/sex), and 24 months (10/sex). Histopathology was evaluated only in the control and 300-ppm groups at 6 (5/sex), 12 (5/sex), and 18 months (20/sex). At 24 months, histopathological examinations were conducted in organs of all surviving animals, including the respiratory system and sections through the nasal turbinates (number not indicated). No treatment-related non-neoplastic effects were observed in the exposed animals. Although the male rats exposed to 300 ppm had a significant increase in body weight compared to controls, no concentration-response was evident. At the end of the exposure period, the female rats exposed to 100 or 300 ppm exhibited a slight but significant reduction in hematocrit; an increase in the mean corpuscular hemoglobin concentration was also noted but only in the females exposed to 300 ppm. The highest concentration examined in this study, 300 ppm, is designated as a NOAEL for toxicity remote from the respiratory tract in rats. CIIT (1980) reported that the technical and raw data were not audited by their quality assurance group during the study period, although CIIT did conduct a quality assessment procedure to review the data. The available pathology reports containing these data indicate that at least the lower respiratory tract was examined. Communication with the testing sponsor has provided information indicating that only one section was examined from the nasal cavity of these test animals. It is not clear whether this single section would have been sufficient to elucidate the areas of lesions noted in the NTP (1990) study. Consequently, the designation of the 300-ppm exposure level as a NOAEL for respiratory lesions (see NTP,1990) is problematic.

Fischer 344/N rats (10/sex/group) were exposed to toluene vapors at 0, 100, 625, 1250, 2500, and 3000 ppm (0, 377, 2355, 4711, 9422, and 11,307 mg/cu.m, respectively) 6.5 hours/day, 5 days/week (duration-adjusted to 0, 73, 455, 911, 1823, and 2187 mg/cu.m, respectively) for 15 weeks (NTP, 1990). Organ weights were measured and histological examinations were performed only on controls, 2500- and 3000-ppm groups, and animals that died before the end of the study. Eight of 10 males exposed to 3000 ppm died, all during the 2nd exposure week. No females died at any exposure level. Compared to the controls, final body weights were 15 and 25% lower in the males and 15 and 14% lower in the females of the 2500- and 3000-ppm groups, respectively. There was a concentration-related increase in the relative liver weight, significant at 1250, 2500, and 3000 ppm in males and at 2500 and 3000 ppm in females. The relative weights of the heart, lung, kidney, and right testis were also significantly elevated in the 2500- and 3000-ppm animals compared to those of

the controls, although no histopathology was observed in any exposure group. Toxic effects noted in a concurrently conducted gavage study (urinary bladder hemorrhages in the two highest exposure groups) were not noted in this subchronic inhalation study. A LOAEL of 2500 ppm [LOAEL(HEC) = 1823 mg/cu.m] was determined for the decrease in body weight gain in both males and females, and the NOAEL for this effect was 1250 ppm [NOAEL(HEC) = 911 mg/cu.m].

Toluene has been suspected to cause congenital defects in infants born to mothers who were exposed to or who abused toluene during pregnancy. In a case report study, Hersh et al. (1985) describes clinical and morphometric characteristics common to 3 children whose mothers had abused toluene (but apparently not alcohol or any other substance) for a period of 4-5 years including during their pregnancies with the affected children. Clinical findings common to these three children included microcephaly, CNS dysfunction, attention deficits, and developmental delay/mental deficiency. Phenotypic similarities included a small midface, deep-set eyes, micrognathia (smallness of the jaws), and blunting of the fingertips. A retrospective cohort study was conducted by McDonald et al. (1987) who examined the history of exposure to chemicals of 301 women who had recently given birth to an infant with an important congenital defect. An identical number of women (referents) who had given birth to normal children were matched with respect to age, employment (hours/week), date of delivery, and educational level. In initial matched-pair analysis, chemical exposure was higher in the cases than in the referents (63 cases:47 referents) due to excess cardiac and miscellaneous defects. In further analysis by chemical categories, only exposure to aromatic solvents showed a clear excess of defects, mostly in the urinary tract. Details of these cases (n = 19) showed that toluene was identified as the solvent in 11 of these cases.

Hudak and Ungvary (1978) exposed three groups of pregnant CFY rats to toluene during different periods of gestation and for different durations of exposure. Two of the groups had their own control group exposed to air only and matched for period and daily duration. The first of these (n = 19) was exposed to 1500 mg/cu.m for 24 hours/day during gestational days 9 to 14. Two dams died during these exposures. No details on the deaths are given but no other maternal toxicity was observed. Fetotoxicity was also in evidence as sternebral alterations (6% vs. 1% in controls), extra ribs (22% vs. 0% in controls), and the presence of fetuses with missing tails (2/213, none observed in 315 controls) were recorded. Under these exposure conditions, 1500 mg/cu.m is a LOAEL for fetotoxicity and a frank effect level (FEL) for maternal toxicity. The second group (n = 14) received this same concentration continuously but on days 1-8 of gestation. Five dams died under these exposure conditions although toxicity parameters of the surviving dams were identical with the controls from the first group (gestational days 9-14). Slight hydrocephaly was noted in 4 fetuses (all from the same litter), and 17% growth retardation was noted vs. 7% in the controls. Thus these exposure conditions are a FEL for maternal toxicity and a LOAEL for fetotoxicity. A third group was exposed to 1000 mg/cu.m for 8 hours/day from the 1st to the 21st day of gestation. No maternal deaths or toxicity occurred. Minor skeletal retardation was present in the exposed fetuses at a higher incidence rate (25%) than in concurrent controls (0%). These results indicate that 1000 mg/cu.m is a LOAEL for developmental effects under these exposure conditions. This concentration is also a NOAEL for maternal effects. These workers also exposed groups of pregnant CFLP mice (n = 11-15) to either air or 1500 or 500 mg/cu.m toluene continuously during days 6-13 of pregnancy. All mice exposed to the

high concentration died within 24 hours of the beginning of exposure. No dams died in the lower exposure group. In this group, the average fetal weight decreased to 0.96 g from the average control weight of 1.07 g, and the percentage of weight-retarded fetuses (less than 0.9 g) increased to 27.6% from 6.5% in the controls. No difference in incidence of skeletal malformations or anomalies was noted between these and control fetuses. For mice, 1500 mg/cu.m is an FEL and 500 mg/cu.m is a mild LOAEL. Since duration adjustment is not performed for developmental effects, this concentration is also the LOAEL(HEC).

B6C3F1 mice (60/sex/group) were exposed to 0, 120, 600, or 1200 ppm (0, 452, 2261, or 4523 mg/cu.m, respectively) toluene 6.5 hours/day, 5 days/week (duration-adjusted to 0, 87, 47, and 875 mg/cu.m, respectively) for 2 years (NTP, 1990). Mean body weights were not significantly different among groups and no treatment-related clinical signs were observed. Deaths (moribund and natural) occurred in all exposure groups but were not related to exposure and were not greater than the control rates. An excess incidence of non-neoplastic inflammatory lesions of the urinary and genital system was observed in all the groups of male mice. At the 15-month interim sacrifice, minimal hyperplasia in the bronchial epithelium was observed in 4/10 females exposed to 1200 ppm. At the end of the study, there was a concentration-dependent increase in the incidence of splenic pigmentation in the exposed males (9/60, 11/60, and 18/59 at 120, 600, and 1200 ppm, respectively) compared to controls (4/60). In the females, the incidence was 37/50, 33/50, 34/49, and 28/47 at 0, 120, 600, and 1200 ppm, respectively. The occurrence of endometrial hyperplasia was present in 14% of the animals exposed to the highest concentration but only in 4% in the low-exposure groups and controls. No differences were noted between the exposed and control mice of either sex in the incidence of degeneration of either the olfactory or respiratory epithelium. No other non-neoplastic lesions were observed in exposed mice. As no adverse effects were noted in this study, the highest concentration, 1200 ppm was designated as a NOAEL in mice for this chronic study [NOAEL(HEC) = 875 mg/cu.m].

Sprague-Dawley rats (15/sex/group) were exposed to cumulative mean exposures of 0, 100, or 1481 ppm (0, 377, or 5653 mg/cu.m) toluene vapors, 6 hours/day, 5 days/week (duration-adjusted to 0, 67, and 1009 mg/cu.m, respectively) for 26 weeks (API, 1981). On weeks 9, 18, and 27, neurohistopathological examinations were conducted in 3-5 rats/sex/group. Hematology, clinical chemistry, and urinalysis parameters were evaluated after 13 and 26 weeks of exposure. Body weights were measured weekly. No significant treatment-related effects were reported. Therefore, a NOAEL of 1481 ppm [NOAEL(HEC) = 1009 mg/cu.m] toluene was determined for systemic effects in rats. The study was limited because there were no other neurohistopathological examinations or organ weight measurements conducted on the animals.

Inhalation exposure to toluene has been shown to result in irreversible high-frequency hearing loss in rats. Pryor et al. (1984) exposed young male Fischer 344 rats to a variety of exposure concentrations and durations. Hearing loss was evaluated by a behavioral technique (avoidance response elicited to an auditory signal) or brainstem auditory-evoked responses (elicited by tone pips of differing loudness and frequency and detected by subdural scalp electrodes). Hearing loss, as measured by both techniques, was observed after as few as 2 weeks exposure to 1000 ppm toluene for 14 hours/day. Lower concentrations of 700 ppm for 14 hours/day were without

effect after 16 weeks of exposure. Intermittent exposure to 3000 ppm for 30 minutes/hour for 8 hours/day caused hearing loss within 2 weeks, whereas a similar exposure schedule for only 4 hours/day was without effect after 9 weeks. These data define a NOAEL for hearing loss in rats of 700 ppm [NOAEL(HEC) = 2638 mg/cu.m]. The duration-adjusted HEC (assumed 5 days/week) would be 14/24 hours x 5/7 days = 1100 mg/cu.m. Although these results clearly document hearing loss in young adult rats, their direct significance to humans remains unclear. Among chronic toluene abusers there is only a single report of adverse effects on hearing; Metrick and Brenner (1982) claimed that the abnormal auditory-evoked potentials recorded in two chronic toluene abusers was evidence of brainstem abnormalities.

Pregnant Wistar rats and hamsters (group size not indicated) inhaled 0 or 800 mg/cu.m toluene vapors 6 hours/day on gestational days 14-20 (rats) or gestational days 6 to 11 (hamsters) (DaSilva et al., 1990). In the exposed rats, there was a significant ($p<0.05$) increase in the number of litters with one or more low birth weight pups (less than 4.9 g), from 10% in the controls to 54% in the exposed dams. A decrease ($p<0.05$) in the number of live pups at birth was also noted in the litters of exposed dams. No evaluation of malformations or anomalies was performed. The neurobehavioral development of the offspring of the exposed rats was assessed using tests of spontaneous alternation, rim escape, and avoidance responses. The only effect noted in the rats, a shortened first trial latency in choosing one side of a maze, was minimal and its significance unclear. No comparable reproductive deficits occurred in the exposed hamsters. The only effect noted in the neurobehavioral tests of the hamster offspring was an equivocal effect in rota-rod performance. No neurobehavioral effect levels were designated from this study, although it appears that the rat developmental processes are more sensitive than those of the hamster, exhibiting adverse effects at 800 mg/cu.m.

Ungvary and Tatrai (1985) exposed New Zealand rabbits (8-10/group) to 0, 500, or 1000 mg/cu.m toluene, 24 hours/day, on gestational days 7-20, and CFLP mice (15 females/group) to 0, 500, 1000, or 1500 mg/cu.m toluene, also continuously, on gestational days 6-15. The control groups consisted of 115 mice and 60 rabbits. All the female mice exposed to 1500 mg/cu.m died. In the mice exposed to 1000 mg/cu.m, there was an increase in fetuses with retarded weight (29%, level of retardation not indicated) and in fetuses with skeletal retardation (12%) compared to 7% and 5%, respectively, in the controls, which did not differ from the animals exposed to 500 mg/cu.m. Of the 8 pregnant rabbits exposed to 1000 mg/cu.m, 2 died, 4 had spontaneous abortions, and the remaining 2 had total litter resorption. No deaths occurred in the 10 rabbits exposed to 500 mg/cu.m but 1/10 rabbits had a spontaneous abortion (as compared to 0/60 reported for the controls). A NOAEL(HEC) of 500 mg/cu.m toluene was determined for reproductive effects in mice. For rabbits, the 500 mg/cu.m concentration is designated as a LOAEL. These results indicate that pregnant mice may be a sensitive population to the effects of toluene.

Pregnant Charles River CD-1 mice (15-16 females/group) inhaled filtered air or 200 or 400 ppm (754 and 1508 mg/cu.m) toluene 7 hours/day on gestational days 7-16 (Courtney et al., 1986). The relative liver weight in the exposed dams was reported to be significantly lower in the two exposed groups compared to the controls, although no data were presented. A statistically significant increase in lactate dehydrogenase activity in the brain of the dams exposed to 400 ppm was also reported. The exposed pregnant

mice did not exhibit any significant differences in the number of implantation sites, number of live fetuses, fetal deaths, or fetal body weight compared to the control values. A statistically significant increase over controls in the incidence (both per litter and per fetus) of enlarged renal pelves was noted in dams exposed to 200 ppm but not 400 ppm. A statistically significant alteration from controls in the rib profile (percentage of fetuses with 1 or 2 additional/fewer ribs) was reported for fetuses from dams exposed to 400 ppm but not 200 ppm. The toxicological significance of this finding is not clear. As no clearly significant toxicological effects were observed, the highest concentration used, 400 ppm [NOAEL(HEC) = 1508 mg/cu.m] is designated as a NOAEL for reproductive and developmental effects in mice.

A 2-generation inhalation reproductive study was conducted in CD rats (10-40 males, 20-80 females/group) (API, 1985). Animals were exposed by whole-body inhalation to toluene at 0, 100, 500, or 2000 ppm (0, 377, 1885, or 7538 mg/cu.m, respectively) 6 hours/day, 7 days/week for 80 days and a 15-day mating period. The mated females were then exposed to the same concentrations during days 1-20 of gestation and days 5-20 of lactation. After weaning, the pups in this generation (F1) were exposed 80 times and then randomly mated with members of the same exposure group (2 females/1 male) to produce the second generation (F2). Mean male body weights were slightly reduced (maximum of 10%) in the first 2 weeks of the exposure in the animals exposed to 500 and 2000 ppm, although the size of the reduction was not related to exposure. No differences were observed in male or female fertility indices, length of gestation, mean numbers of viable and nonviable pups at birth, or pup survival indices during lactation. No abnormal histopathology was noted in organs examined. A significant decrease ($p<0.05$) in weight relative to controls was observed in the first generation offspring. The decrease was maintained throughout the lactation period in the pups from dams exposed to the highest exposure and in those from the ancillary group in which females exposed to the 2000 ppm concentration were mated with males having no exposure. No data were available in the report about the F2 generation. Based on the effects on the pups of the first generation (F1), a LOAEL of 2000 ppm [LOAEL(HEC) = 7538 mg/cu.m] is designated, the NOAEL being 500 ppm [NOAEL(HEC) = 1885 mg/cu.m].

I.B.5. CONFIDENCE IN THE INHALATION RfC

Study -- Medium
Data Base -- Medium
RfC -- Medium

The study of Foo et al. (1990) indicates adverse neurological effects of toluene in a small worker population. These effects are consistent with more severe CNS effects occurring at abusive concentrations of toluene and could not have been confounded by alcohol as the control and exposed populations did not use alcohol. However, the paucity of exposure information and identification of only a LOAEL is not sufficient to warrant a higher confidence than medium for this study.

Other studies indicate that irritation may occur at around the same concentration, 100 ppm (Baelum et al., 1985; Echeverria et al., 1989). In

regard to this effect, the NTP (1990) rat chronic inhalation study was well conducted, established the rat as the most sensitive species, examined an adequate number of animals, and performed histopathology on all major organs, including the brain and the respiratory tract. The sensitive endpoint was the concentration-dependent degeneration of the nasal epithelium characterized by the erosion of the olfactory epithelium and degeneration of the respiratory epithelium in male rats. The NTP study is also given medium confidence, however, as it did not establish a NOAEL.

Although this data base has a complement of chronic laboratory animal studies, long-term data in humans are not available for either the neurotoxicity or irritation endpoints. The reproductive/developmental studies in three species were not comprehensive in endpoint evaluation but do identify the rabbit as the most sensitive species. The data base is thus given a medium confidence rating. A medium confidence rating for the RfC follows.

___I.B.6. EPA DOCUMENTATION AND REVIEW OF THE INHALATION RfC

Source Document -- This assessment is not presented in any existing U.S. EPA document.

Other EPA Documentation -- U.S. EPA, 1984, 1985

Agency Work Group Review -- 04/21/1988, 05/26/1988, 02/16/1989, 03/21/1989, 05/18/1989,
08/15/1991, 12/11/1991

Verification Date -- 05/18/1989, 12/11/1991

___I.B.7. EPA CONTACTS (INHALATION RfC)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

_II. CARCINOGENICITY ASSESSMENT FOR LIFETIME EXPOSURE

Substance Name -- Toluene

CASRN -- 108-88-3
Last Revised -- 02/01/1994

Section II provides information on three aspects of the carcinogenic assessment for the substance in question; the weight-of-evidence judgment of the likelihood that the substance is a human carcinogen, and quantitative estimates of risk from oral exposure and from inhalation exposure. The quantitative risk estimates are presented in three ways. The slope factor is the result of application of a low-dose extrapolation procedure and is presented as the risk per (mg/kg)/day. The unit risk is the quantitative estimate in terms of either risk per ug/L drinking water or risk per ug/cu.m air breathed. The third form in which risk is presented is a drinking water or air concentration providing cancer risks of 1 in 10,000, 1 in 100,000 or 1 in 1,000,000. The rationale and methods used to develop the carcinogenicity information in IRIS are described in The Risk Assessment Guidelines of 1986 (EPA/600/8-87/045) and in the IRIS Background Document. IRIS summaries developed since the publication of EPA's more recent Proposed Guidelines for Carcinogen Risk Assessment also utilize those Guidelines where indicated (Federal Register 61(79):17960-18011, April 23, 1996). Users are referred to Section I of this IRIS file for information on long-term toxic effects other than carcinogenicity.

__II.A. EVIDENCE FOR CLASSIFICATION AS TO HUMAN CARCINOGENICITY

___II.A.1. WEIGHT-OF-EVIDENCE CLASSIFICATION

Classification -- D; not classified

Basis -- No human data and inadequate animal data. Toluene did not produce positive results in the majority of genotoxic assays.

___II.A.2. HUMAN CARCINOGENICITY DATA

None.

___II.A.3. ANIMAL CARCINOGENICITY DATA

A chronic (106-week) bioassay of toluene in F344 rats of both sexes

reported no carcinogenic responses (CIIT, 1980). A total of 960 rats were exposed by inhalation for 6 hours/day, 5 days/week to toluene at 0, 30, 100, or 300 ppm. Groups of 20/sex/dose were sacrificed at 18 months. Gross and microscopic examination of tissues and organs identified no increase in neoplastic tissue or tumor masses among treated rats when compared with controls. The study is considered inadequate because the highest dose administered was well below the MTD for toluene and because of the high incidence of lesions and pathological changes in the control animals.

Several studies have examined the carcinogenicity of toluene following repeated dermal applications. Toluene (dose not reported) applied to shaved interscapular skin of 54 male mice (strains A/He, C3HeB, SWR) throughout their lifetime (3 times weekly) produced no carcinogen1c response (Poel, 1963). One drop of toluene (about 6 mL) applied to the dorsal skin of 20 random-bred albino mice twice weekly for 50 weeks caused no skin papillomas or carcinomas after a 1-year latency period was allowed (Coombs et al., 1973). No increase in the incidence of skin or systemic tumors was demonstrated in male or female mice of three strains (CF, C3H, or CBaH) when toluene was applied to the back of 25 mice of each sex of each strain at 0.05-0.1 mL/mouse, twice weekly for 56 weeks (Doak et al., 1976). One skin papilloma and a single skin carcinoma were reported among a group of 30 mice treated dermally with one drop of 0.2% (w/v) solution toluene twice weekly, administered from droppers delivering 16-20 uL per drop for 72 weeks (Lijinsky and Garcia, 1972). It is not reported whether evaporation of toluene from the skin was prevented during these studies.

II.A.4. SUPPORTING DATA FOR CARCINOGENICITY

Toluene was found to be nonmutagenic in reverse mutation assays with S. typhimurium (Mortelmans and Riccio, 1980; Nestmann et al., 1980; Bos et al., 1981; Litton Bionetics, Inc., 1981; Snow et al., 1981) and E. coli (Mortelmans and Riccio, 1980), with and without metabolic activation. Toluene did not induce mitotic gene conversion (Litton Bionetics, Inc., 1981; Mortelmans and Riccio, 1980) or mitotic crossing over (Mortelmans and Riccio, 1980) in S. cerevisiae. Although Litton Bionetics, Inc. (1981) reported that toluene did not cause increased chromosomal aberrations in bone marrow cells, several Russian studies (Dobrokhotov, 1972; Lyapkalo, 1973) report toluene as effective in causing chromosal damage in bone marrow cells of rats. There was no evidence of chromosomal aberrations in blood lymphocytes of workers exposed to toluene only (Maki-Paakkanen et al., 1980; Forni et al., 1971), although a slight increase was noted in workers exposed to toluene and benzene (Forni et al., 1971; Funes-Craviota et al., 1977). This finding is supported by studies of cultured human lymphocytes exposed to toluene in vitro; no elevation of chromosomal aberrations or sister chromatid exchanges was observed (Gerner-Smidt and Friedrich, 1978).

__II.B. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM ORAL EXPOSURE

Not available.

__II.C. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM INHALATION EXPOSURE

Not available.

__II.D. EPA DOCUMENTATION, REVIEW, AND CONTACTS (CARCINOGENICITY ASSESSMENT)

___II.D.1. EPA DOCUMENTATION

Source Document -- U.S. EPA, 1987

The values in the 1987 Drinking Water Criteria Document for Toluene have received peer and administrative review.

___II.D.2. REVIEW (CARCINOGENICITY ASSESSMENT)

Agency Work Group Review -- 09/15/1987

Verification Date -- 09/15/1987

___II.D.3. U.S. EPA CONTACTS (CARCINOGENICITY ASSESSMENT)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

_VII. REVISION HISTORY

Substance Name -- Toluene
CASRN -- 108-88-3

Date	Section	Description
03/01/1988	I.A.4.	Text revised
09/07/1988	II.	Carcinogen summary on-line
02/01/1989	II.D.3.	Secondary contact's phone number corrected
07/01/1989	I.B.	Inhalation RfD now under review
03/01/1990	VI.	Bibliography on-line
04/01/1990	VI.C.	Combs et al., 1973 citation corrected
06/01/1990	IV.A.1.	Area code for EPA contact corrected
06/01/1990	IV.F.1.	EPA contact changed
07/01/1990	I.A.	Withdrawn; new RfD verified (in preparation)
07/01/1990	VI.A.	Oral RfD references withdrawn
08/01/1990	I.A.	Oral RfD summary replaced; RfD changed
08/01/1990	II.	Text edited
08/01/1990	VI.A.	Oral RfD references revised
09/01/1990	III.A.	Health Advisory on-line
09/01/1990	VI.D.	Health Advisory references added
08/01/1991	VI.C.	Litton Bionetics, Inc., 1981 reference title clarified
01/01/1992	IV.	Regulatory actions updated
04/01/1992	IV.A.1.	CAA regulatory action withdrawn
08/01/1992	I.B.	Inhalation RfC on-line
08/01/1992	VI.B.	Inhalation references on-line
02/01/1994	II.D.3.	Secondary contact's phone number changed
04/01/1994	I.A.7.	Primary contact changed
04/01/1997	III.,IV., V.	Drinking Water Health Advisories, EPA Regulatory Actions, and Supplementary Data were removed from IRIS on or before April 1997. IRIS users were directed to the appropriate EPA Program Offices for this information.

Drinking Water and Health

As part of the Drinking Water and Health pages, this fact sheet is part of a larger publication:

National Primary Drinking Water Regulations

Consumer Factsheet on: TOLUENE

This is a factsheet about a chemical that may be found in some public or private drinking water supplies. It may cause health problems if found in amounts greater than the health standard set by the United States Environmental Protection Agency (EPA).

What is Toluene and how is it used?

Toluene is an organic liquid with a sweet, benzene-like odor. The largest chemical use for toluene is to make benzene and urethane.

The list of trade names given below may help you find out whether you are using this chemical at home or work.

Trade Names and Synonyms:

Methylbenzene
Methacide
Phenylmethane
Toluol
Antisal 1A

Why is Toluene being Regulated?

In 1974, Congress passed the Safe Drinking Water Act. This law requires EPA to determine safe levels of chemicals in drinking water which do or may cause health problems. These non-enforceable levels, based solely on possible health risks and exposure, are called Maximum Contaminant Level Goals.

The MCLG for toluene has been set at 1 parts per million (ppm) because EPA believes this level of protection would not cause any of the potential health problems described below.

Based on this MCLG, EPA has set an enforceable standard called a Maximum Contaminant Level (MCL). MCLs are set as close to the MCLGs as possible, considering the ability of public water systems to detect and remove contaminants using suitable treatment technologies.

The MCL has also been set at 1 ppm because EPA believes, given present technology and resources, this is the lowest level to which water systems can reasonably be required to remove this contaminant should it occur in drinking water.

These drinking water standards and the regulations for ensuring these standards are met, are called National Primary Drinking Water Regulations. All public water supplies must abide by these regulations.

What are the Health Effects?

Short-term: EPA has found toluene to potentially cause the following health effects when people are exposed to it at levels above the MCL for relatively short periods of time: minor nervous system disorders such as fatigue, nausea, weakness, confusion.

Long-term: Toluene has the potential to cause the following effects from a lifetime exposure at levels above the MCL: more pronounced nervous disorders such as spasms, tremors, impairment of speech, hearing, vision, memory, coordination; liver and kidney damage.

How much Toluene is produced and released to the environment?

Production of toluene was 6.4 billion lbs in 1993. It is released into the atmosphere principally from the volatilization of petroleum fuels and toluene-based solvents and thinners and from motor vehicle exhaust. It is also released in wastewaters or by spills on land during the storage, transport and disposal of fuels and oils.

From 1987 to 1993, according to EPA's Toxic Chemical Release Inventory, toluene releases to land and water totalled over 4 million lbs., primarily from petroleum refining industries. The largest releases occurred in Texas and California. The largest releases directly to water occurred in Connecticut and West Virginia.

What happens to Toluene when it is released to the environment?

Toluene released to soil will be lost by evaporation from near-surface soil and by leaching to the groundwater. Its breakdown by soil microbes is slow. Toluene evaporates within a few hours when released to water, and it has little tendency to accumulate in aquatic life.

How will Toluene be Detected in and Removed from My Drinking Water?

The regulation for toluene became effective in 1992. Between 1993 and 1995, EPA required your water supplier to collect water samples every 3 months for one year and analyze them to find out if toluene is present above 0.5 ppb. If it is present above this level, the system must continue to monitor this contaminant.

If contaminant levels are found to be consistently above the MCL, your water supplier must take steps to reduce the amount of toluene so that it is consistently below that level. The following treatment methods have been approved by EPA for removing toluene: Granular activated charcoal in combination with Packed Tower Aeration.

How will I know if Toluene is in my drinking water?

If the levels of toluene exceed the MCL, 1 ppm, the system must notify the public via newspapers, radio, TV and other means. Additional actions, such as providing alternative drinking water supplies, may be required to prevent serious risks to public health.

Drinking Water Standards:

Mclg: 1 ppm

Mcl: 1 ppm

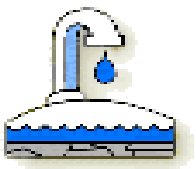
Learn more about your drinking water!

EPA strongly encourages people to learn more about their drinking water, and to support local efforts to protect and upgrade the supply of safe drinking water. Your water bill or telephone books government listings are a good starting point.



Your local water supplier can give you a list of the chemicals they test for in your water, as well as how your water is treated.

Your state Department of Health/Environment is also a valuable source of information.

For help in locating these agencies or for information on drinking water in general, call: EPAs Safe Drinking Water Hotline: (800) 426-4791.

For additional information on the uses and releases of chemicals in your state, contact the: Community Right-to-Know Hotline: (800) 535-0202.

OPPT Chemical Fact Sheet EPA 749-F-94-021

CHEMICALS IN THE ENVIRONMENT: TOLUENE (CAS NO. 108-88-3)

prepared by
OFFICE OF POLLUTION PREVENTION AND TOXICS
U.S. ENVIRONMENTAL PROTECTION AGENCY
August 1994

Chemicals can be released to the environment as a result of their manufacture, processing, and use. EPA has developed information summaries on selected chemicals to describe how you might be exposed to these chemicals, how exposure to them might affect you and the environment, what happens to them in the environment, who regulates them, and whom to contact for additional information. EPA is committed to reducing environmental releases of chemicals through source reduction and other practices that reduce creation of pollutants.

WHAT IS TOLUENE, HOW IS IT USED, AND HOW MIGHT I BE EXPOSED?

Toluene (also called methyl benzene) is a colorless, flammable liquid. It occurs naturally in petroleum crude oil. Petroleum crude oil is by far the largest source of toluene. Most (up to a billion pounds each year) of this toluene is never isolated from crude oil. Refineries pump this "unrecovered" toluene to some other location where it is added directly to gasoline. The toluene that is isolated is "recovered" in large amounts (approximately 800 million gallons in 1991) by twenty companies in the United States. US demand for toluene is expected to grow moderately over the next several years. The largest users of "recovered" toluene are companies that make benzene. Companies also add toluene to aerosol spray paints, wall paints, lacquers, paint strippers, adhesives, printing ink, spot removers, cosmetics, perfumes, and antifreeze.

Exposure to toluene can occur in the workplace or in the environment following releases to air, water, land, or groundwater. Exposure can also occur when people use gasoline and other products that contain toluene. Toluene enters the body when breathed in with contaminated air or when consumed with contaminated food or water. It can also be absorbed through skin contact. Toluene does not remain in the body due to its breakdown and removal.

WHAT HAPPENS TO TOLUENE IN THE ENVIRONMENT?

Toluene evaporates when exposed to air. It dissolves only slightly when mixed with water. Most direct releases of toluene to the environment are to air. Toluene also evaporates from water and soil exposed to air. Once in air, toluene breaks down to other chemicals. Microorganisms that live in water and in soil can also break down toluene. Because it is a liquid that does not bind well to soil, toluene that makes its way into the ground can move through the ground and enter groundwater. Plants and animals are not likely to store toluene.

HOW DOES TOLUENE AFFECT HUMAN HEALTH AND THE ENVIRONMENT?

Effects of toluene on human health and the environment depend on how much toluene is present and the length and frequency of exposure. Effects also depend on the health of a person or the condition of the environment

when exposure occurs.

Breathing large amounts of toluene for short periods of time adversely affects the human nervous system, the kidneys, the liver, and the heart. Effects range from unsteadiness and tingling in fingers and toes to unconsciousness and death. Direct, prolonged contact with toluene liquid or vapor irritates the skin and the eyes. These effects are not likely to occur at levels of toluene that are normally found in the environment.

Human health effects associated with breathing or otherwise consuming smaller amounts of toluene over long periods of time are not known. Repeatedly breathing large amounts of toluene, such as when "sniffing" glue or paint, can cause permanent brain damage. As a result, humans can develop problems with speech, hearing, and vision. Humans can also experience loss of muscle control, loss of memory, and decreased mental ability. Exposure to toluene can also adversely affect the kidneys. Laboratory animal studies and, in some cases, human exposure studies show that repeat exposure to large amounts of toluene during pregnancy can adversely affect the developing fetus. Other studies show that repeat exposure to large amounts of toluene adversely affects the nervous system, the kidneys, and the liver of animals.

Toluene by itself is not likely to cause environmental harm at levels normally found in the environment. Toluene can contribute to the formation of photochemical smog when it reacts with other volatile organic carbon substances in air.

CHEMICAL SUMMARY FOR TOLUENE

prepared by
OFFICE OF POLLUTION PREVENTION AND TOXICS
U.S. ENVIRONMENTAL PROTECTION AGENCY
August 1994

This summary is based on information retrieved from a systematic search limited to secondary sources (see Appendix A). These sources include online databases, unpublished EPA information, government publications, review documents, and standard reference materials. No attempt has been made to verify information in these databases and secondary sources.

I. CHEMICAL IDENTITY AND PHYSICAL/CHEMICAL PROPERTIES

The chemical identity and physical/chemical properties of toluene are summarized in Table 1.

TABLE 1. CHEMICAL IDENTITY AND CHEMICAL/PHYSICAL PROPERTIES OF TOLUENE

Characteristic/Property	Data	Reference
CAS No.	108-88-3	
Common Synonyms	Methyl benzene, Toluol, Phenylmethane	Budavari et al. 1989
Molecular Formula	C7H8	
Chemical Structure		
Physical State	Liquid	Budavari et al. 1989
Molecular Weight	92.13	Budavari et al. 1989
Melting Point	-95øC	Budavari et al. 1989
Boiling Point	110.6øC	Budavari et al. 1989
Water Solubility	470 mg/L @ 16øC; 515 mg/L @ 20øC	Verschueren 1983
Density	0.87 g/mL @ 20øC	Keith and Walters 1985
Vapor Density (air = 1)	3.14	Verschueren 1983
KOC	259	U.S. Air Force 1989
Log KOW	2.73	Leo 1983
Vapor Pressure	22.0 mm Hg @ 20øC	Verschueren 1983
Reactivity	Reacts vigorously with strong oxidizing agents and may generate heat or possibly ignite or explode.	NFPA 1975
Flash Point	4.40øC closed cup	Hawley 1981
Henry's Law Constant	6.61 X 10-3 atm m3/mol @ 25øC	U.S. Air Force 1989
Fish Bioconcentration Factor	20 (in bluegill), 24 (in crayfish)	U.S. EPA 1984
Odor Threshold	2.90 ppm (in air)	U.S. Air Force 1989
Conversion Factors	1 ppm = 3.77 mg/m3 1 mg/m3 = 0.27 ppm	U.S. EPA 1990

II. PRODUCTION, USE, AND TRENDS

A. Production

Almost all toluene is derived from petroleum processing; most is never recovered. This 'contained' toluene, estimated to considerably exceed one billion pounds annually, is incorporated directly into gasoline.

There are 20 toluene-producing companies in the United States with the capacity to isolate at least 15 million gallons per year: Amerada Hess, American Petrofina, Amoco Oil, Ashland Oil, BP Chemicals, Champlin, Chevron Chemical, Coastal Corp., Dow Chemical, Exxon Chemical, Koch Industries, Lyondell Petrochemical, Marathon Oil, Mobil Oil, Oxy Petrochemicals, Phillips Petroleum, Shell Chemical, Sun Company, Texaco, and Triangle Refining. These companies represent over 90 percent of US capacity. Annual production capacity for toluene is estimated at 1.5 to 1.7 billion gallons. In 1991, just over 800 million gallons of toluene were isolated in the US. In the same year, 62 million gallons were imported and 52 million gallons were exported (Mannsville 1992).

B. Use

The largest use for toluene is in the production of benzene. Toluene is also used as an octane booster or enhancer in gasoline, as a raw material for toluene diisocyanate, as a solvent, and in solvent extraction processes. As a solvent, it may be used in aerosol spray paints, wall paints, lacquers, inks, adhesives, natural gums, and resins, as well as in a number of consumer products, such as spot removers, paint strippers, cosmetics, perfumes, and antifreezes. Table 2 shows the estimated 1992 US end-use pattern for toluene.

C. Trends

Demand for toluene in the US is expected to experience modest growth over the next several years. Growth in demand for toluene in gasoline appears to be slowing, and benzene demand is expected to grow at approximately 3 percent per year. Demand for toluene in other uses is expected to remain stable.

TABLE 2. Estimated 1992 United States End-Use Pattern of Toluene

Use of Toluene (typical Standard Industrial Classification (SIC) Code) (see end note 1)	Percentage of all US Toluene Use
Benzene production (production, SIC 2865; use, various industries)	50%
Gasoline blending (production, SIC 2911; sold in SIC 5541; use, various industries)	30%
Toluene diisocyanate production (production, SIC 2865; use, various industries)	7%
Solvents (used in many industries, including 2851 and 2893)	6%
Miscellaneous chemicals (production, SIC 28; use, various industries)	7%

Source: Mannsville 1992.

III. ENVIRONMENTAL FATE

A. Environmental Release

Of the total toluene released to the environment almost all is released to the air. Toluene is a volatile liquid [vapor pressure, 22 mm Hg at 20øC (Verschueren 1983)], and is released into the atmosphere from industrial and consumer uses. The largest sources of toluene release are the evaporation from gasoline, which is 5-7% toluene, and release through car exhausts. Spills of gasoline and industrial releases to surface water and soil are believed to be only a small fraction of the amount released to the atmosphere (ATSDR 1993). In 1992 releases of toluene to environmental media, as reported to the Toxic Chemical Release Inventory by certain types of U.S. industries totaled about 193 million pounds. Of this amount, a total of 191 million pounds (99%) were released to the atmosphere, 84 thousand pounds were released to surface water, 1.6 million pounds were released to underground injection sites, and 708 thousand pounds were released to land (TRI92 1994). Levels of toluene in environmental media range from 1-30 micrograms/m3 in suburban and urban air and 0.1-2.9 micrograms/L in drinking water. Toluene contamination was detected in a maximum of only about 1.2% of the underground water supplies tested, however. The maximum air concentrations of toluene are found indoors and in one study ranged from 37.8 to 71.1 micrograms/m3. The increased concentration compared to urban outside air could originate from household products such as paints, thinners, glue, infiltration from auto emissions, and from cigarette smoke. Cigarettes contain about 80 micrograms toluene/cigarette (ATSDR 1993).

B. Transport

The majority of toluene evaporates to the atmosphere from the water and soil. It is moderately retarded by adsorption to soils rich in organic material (Koc = 259), therefore, transport to ground water is dependent on the soil composition (ATSDR 1993). In unsaturated topsoil containing organic material, it has been estimated that 97% of the toluene is adsorbed to the soil and only about 2% is in the soil-water phase and transported with flowing groundwater. There is little retardation in sandy soils and 2-13% of the toluene was estimated to migrate with flowing water; the remainder was volatilized, biodegraded, or unaccounted for. In saturated deep soils with no soil-air phase, about 48% may be transported with flowing groundwater (U.S. Air Force 1989).

C. Transformation/Persistence

1. Air - The main degradation pathway for toluene in the atmosphere is reaction with photochemically produced hydroxyl radicals. The estimated atmospheric half life for toluene is about 13 hours. Toluene is also oxidized by reactions with atmospheric nitrogen dioxide, oxygen, and ozone, but these are minor degradation pathways. Photolysis is not considered a significant degradative pathway for toluene (ATSDR 1993).

2. Soil - In surface soil, volatilization to air is an important fate process for toluene (U.S. Air Force 1993). Biodegradation of toluene has been demonstrated in the laboratory to occur with

a half life of about 1 hour. In the environment, biodegradation of toluene to carbon dioxide occurs with a typical half life of 1-7 days (ATSDR 1993).

3. Water - An important fate process for toluene is volatilization, the rate of which depends on the amount of turbulence in the surface water (ATSDR 1993). The volatilization of toluene from static water has a half life of 1-16 days, whereas from turbulent water the half life is 5-6 hours. Degradation of toluene in surface water occurs primarily by biodegradation with a half life of less than one day under favorable conditions (presence of microorganisms, microbial adaptation, and optimum temperature). Biodegradation also occurs in shallow groundwater and in salt water at a reduced rate (ATSDR 1993). No data are available on anaerobic degradation of toluene in deep ground water conditions where aerobic degradation would be minimal (ATSDR 1993).

4. Biota - Bioaccumulation in most organisms is limited by the metabolism of toluene into more polar compounds that have greater water solubility and a lower affinity for lipids. Bioaccumulation in the food chain is predicted to be low (ATSDR 1993; U.S. EPA 1990).

IV. HUMAN HEALTH EFFECTS

A. Pharmacokinetics

1. Absorption - Studies in humans and animals have demonstrated that toluene is readily absorbed via the lungs and the gastrointestinal tract. Absorption through the skin is estimated at about 1% of that absorbed by the lungs when exposed to toluene vapor. Dermal absorption is expected to be higher upon exposure to the liquid; however, exposure is limited by the rapid evaporation of toluene (Faust 1994).

2. Distribution - In studies with mice exposed to radiolabeled toluene by inhalation, high levels of radioactivity were present in body fat, bone marrow, spinal nerves, spinal cord, and brain white matter. Lower levels of radioactivity were present in blood, kidney, and liver. Accumulation of toluene has generally been found in adipose tissue, other tissues with high fat content, and in highly vascularized tissues (Faust 1994).

3. Metabolism - The metabolites of inhaled or ingested toluene include benzyl alcohol resulting from the hydroxylation of the methyl group. Further oxidation results in the formation of benzaldehyde and benzoic acid. The latter is conjugated with glycine to yield hippuric acid or reacted with glucuronic acid to form benzoyl glucuronide. o- cresol and p-cresol formed by ring hydroxylation are considered minor metabolites (Faust 1994).

4. Excretion - Toluene is primarily (60-70%) excreted through the urine as hippuric acid. The excretion of benzoyl glucuronide accounts for 10-20%, and excretion of unchanged toluene through the lungs also accounts for 10-20%. Excretion of hippuric acid is usually complete within 24 hours after exposure (U.S. EPA 1990).

B. Acute Toxicity

Humans exposed to intermediate to high levels of toluene for short periods of time experience adverse central nervous system effects ranging from headaches to intoxication, convulsions, narcosis, and death. Similar effects are observed in short-term animal studies.

1. Humans - Toluene ingestion or inhalation can result in severe central nervous system depression, and in large doses, can act as a narcotic. The ingestion of about 60 mL resulted in fatal nervous system depression within 30 minutes in one reported case. Constriction and necrosis of myocardial fibers, markedly swollen liver, congestion and hemorrhage of the lungs and acute tubular necrosis were found on autopsy (Faust 1994).

   Central nervous system effects (headaches, dizziness, intoxication) and eye irritation occurred following inhalation exposure to 100 ppm toluene 6 hours/day for 4 days. Exposure to 600 ppm for 8 hours resulted in the same and more serious symptoms including euphoria, dilated pupils, convulsions, and nausea (U.S. EPA 1994). Exposure to 10,000-30,000 ppm has been reported to cause narcosis and death (U.S. Air Force 1989). Toluene can also strip the skin of lipids causing dermatitis (Keith and Walters 1985).

2. Animals - LD50/LC50 values for rats, reported in the literature searched, are as follows for the various routes of exposure: 5.3-5.9 g/kg (oral), 4618 ppm for 6 hours (respiratory), 1.64 g/kg (i.p. injection) (U.S. EPA 1990). An LC50 value for mice of 5320 ppm for 7 hours was reported, and a rabbit LD50 of 14.1 mL/kg (12.3 g/kg) was reported for dermal exposure (U.S. EPA 1990).

   The initial effects are instability and incoordination, lacrimation and sniffles (respiratory exposure), followed by narcosis. Animals die of respiratory failure from severe nervous system depression. Cloudy swelling of the kidneys was reported in rats following inhalation exposure to 1600 ppm, 18-20 hours/day for 3 days (U.S. EPA 1990).

C. Subchronic/Chronic Effects

Repeat doses of toluene cause adverse central nervous system effects and can damage the upper respiratory system, the liver, and the kidney. Adverse effects occur as a result from both oral and the inhalation exposures. A reported lowest-observed-effect level in humans for adverse neurobehavioral effects is 88 ppm. EPA has derived both an oral RfD (0.2 mg/kg/day) and an inhalation RfC (0.4 mg/m3) for toluene exposures.

1. Humans - Chronic occupational exposure and incidences of toluene abuse have resulted in hepatomegaly and liver function changes. It has also resulted in nephrotoxicity and, in one case, was a cardiac sensitizer and fatal cardiotoxin.

   Neural and cerebellar dystrophy were reported in several cases of habitual "glue sniffing." An epidemiological study in France on workers chronically exposed to toluene fumes reported leukopenia and neutropenia. Exposure levels were not given in the secondary reference; however, the average urinary excretion of hippuric acid, a metabolite of toluene, was given as 4 g/L compared to a normal level of 0.6 g/L (Sandmeyer 1989).

2. Animals - The major target organs for the subchronic/chronic toxicity of toluene are the nervous system, liver, and kidney. Depressed immune response has been reported in male mice given doses of 105 mg/kg/day for 28 days (Faust 1994). Toluene in corn oil administered to F344 male and female rats by gavage 5 days/week for 13 weeks, induced prostration, hypoactivity, ataxia, piloerection, lacrimation, excess salivation, and body tremors at doses ò2500 mg/kg. Liver, kidney, and heart weights were also increased at this dose and histopathologic lesions were seen in the liver, kidneys, brain and urinary bladder. The no-observed-adverse effect level (NOAEL) for the study was 312 mg/kg (223 mg/kg/day) and the lowest-observed-adverse effect level (LOAEL) for the study was 625 mg/kg (446 mg/kg/day) (U.S. EPA 1994). Based on these data, the U.S. EPA (1994) calculated a chronic RfD (reference dose) for toluene of 0.2 mg/kg/day.

   A 13-week gavage study was also performed in B6C3F1 mice. Central nervous system effects were seen including subconvulsive jerking, prostration, impaired grasping reflex, bradypnea, hypothermia, ataxia, and hypoactivity. Body weight loss was seen in males at 2500 mg/kg; however, no other changes were noted. The NOAEL for this study was 1250 mg/kg.

In an inhalation study with toluene, degeneration in the olfactory and respiratory epithelium of the nasal cavity was observed in Fisher 344 rats exposed 6.5 hours/day, 5 days/week for 103 weeks to 600 ppm toluene. A LOAEL of 600 ppm was determined, but a NOAEL could not be determined from the study (U.S. EPA 1994). Based on these data and the LOAEL of 88 ppm (332 mg/m3) from a human epidemiological study (Section IV G), the U.S. EPA (1994) calculated a chronic inhalation reference concentration (RfC) of 0.4 mg/m3 for toluene from the human exposure data.

D. Carcinogenicity

There is inadequate evidence for the carcinogenicity of toluene in both human and animal studies.

1. Humans - Epidemiology studies revealed no significant increased risk for cancer among workers who were exposed to toluene for at least 5 years. In one study, the incidence of respiratory tract tumors was increased among all workers exposed for a minimum of 3 months. However, when only those workers exposed for 5 years and a latency period of 10 years were considered, the significance of the increase was lost. In another study, the cohort exposed to toluene and other chemicals experienced fewer cancer deaths than the general population (Faust 1994).

2. Animals - Sprague-Dawley rats were given 500 mg toluene/kg 4-5 days/week for 2 years. At the end of the study, 8% of the treated males and 17.5% of the treated females developed hemolymphoreticular neoplasms compared to 7% of the male and 3% of the female controls. Two long-term inhalation studies in rats and mice found no evidence of toluene carcinogenicity. Rats were given up to 300 ppm, 6 hours/day, 5 days/week for 24 months. Mice were given 600 or 1200 ppm, 6.5 hours/day, 5 days/week for 24 months.

   Based on no human and inadequate animal data, the U.S. EPA

cancer classification for toluene is D, not classified (U.S. EPA 1994).

E. Genotoxicity

Toluene has been extensively tested in a variety of genotoxicity tests. Toluene has been shown to be negative for gene mutations in bacteria, in yeast, and in the fruit fly.

Conflicting results have been reported in mammalian cell tests. In vitro mammalian cell tests (including human cells) for sister chromatid exchange and chromosome aberrations have been reported as negative. Toluene was positive in rodent micronucleus tests when administered by injection but negative when administered by the oral route (McGregor 1994).

F. Developmental/Reproductive Toxicity

Exposures to high levels of toluene can result in adverse effects in the developing human fetus. Several studies have indicated that high levels of toluene can also adversely effect the developing offspring in laboratory animals.

1. Humans - Variable growth, microcephaly, CNS dysfunction, attentional deficits, minor craniofacial and limb abnormalities, and developmental delay were seen in three children exposed to toluene in utero as a result of maternal solvent abuse before and during pregnancy (U.S. EPA 1994).

2. Animals - Sternebral alterations, extra ribs, and missing tails were reported following treatment of CFY rats with 1500 mg/m3 toluene 24 hours/day during days 9-14 of gestation. Two of the dams died during the exposure.

   Another group of CFY rats received 1000 mg/m3 8 hours/day during days 1-21 of gestation. No maternal deaths or toxicity occurred, however, minor skeletal retardation was present in the exposed fetuses. CFLP Mice were exposed to 500 or 1500 mg/m3 toluene continuously during days 6-13 of pregnancy. All dams died at the high dose during the first 24 hours of exposure, however none died at 500 mg/m3. Decreased fetal weight was reported, but there were no differences in the incidences of skeletal malformations or anomalies between the treated and control offspring (U.S. EPA 1994).

G. Neurotoxicity

Available information indicate that toluene adversely affects the central nervous system of humans (by inhalation) and of laboratory animals (by oral and inhalation).

1. Humans - A battery of neurobehavioral tests were administered to workers exposed to 88 ppm (332 mg/m3, TWA) toluene and to a control group exposed to 13 ppm (49 mg/m3). A lowest-observed-adverse effect level (LOAEL) of 88 ppm (332 mg/m3) for neurobehavioral changes was determined (U.S.EPA 1994). Nervous system effects including fatigue, muscular weakness, confusion, impaired coordination, slight exhilaration, enlarged pupils and accommodation disturbances were reported in humans chronically exposed to 200-800 ppm toluene, 7-8 hours/day (U.S. EPA 1994). Exposure to 100 ppm for 6 hours

resulted in fatigue, sleepiness, decreased manual dexterity, decreased color discrimination, and decreased accuracy in visual perception. The concentration of 100 ppm is roughly equivalent to 40.39 mg/kg over the 6-hour period.

Prolonged abuse was reported to result in altered electroencephalogram, ataxia, tremors, CNS atrophy, and impaired speech, hearing, and vision (ATSDR 1993).

Magnetic resonance imaging and brainstem auditory evoked response evaluations of the brains of chronic solvent abusers indicate that there are permanent changes in brain structure that correlate with the degree of dysfunction suggesting the neurological symptoms may result from permanent structural changes in the brain (ATSDR 1993).

2. Animals - Alterations in the concentrations of CNS neurotransmitters were reported in male CD-1 mice following treatment with 5-105 mg toluene/kg/day given in drinking water for 28 days. The neurotransmitters affect mood, emotional state, and aggressive behavior. Exposure of mice to 1250 and 2500 mg/kg/day for 13 weeks resulted in increased relative brain weight in male mice at 2500 mg/kg/day and necrosis of brain tissue at both doses. Acute inhalation exposure of monkeys to 1000 and 2000 ppm toluene, which are below the concentrations known to cause neurological impairment, were reported to impair cognitive and motor abilities. Disturbances in the vestibular and optooculomotor systems of rats resulted from acute exposure to 1500 ppm toluene. Exposure of rats to 1500 ppm for 1 hour/day for 14 days also resulted in nystagmus. The cerebellum was suggested as a target site of toluene (ATSDR 1993). Exposure of rats to 1200 ppm for 5 weeks or 1000 ppm for 2 weeks produced permanent high-frequency hearing loss. The hearing loss occurred whether or not the exposure was continuous or episodic and was compounded by post-exposure high noise levels (ATSDR 1993). Decreased neuromuscular performance has been recorded in several studies. A single exposure for 4 hours to 810-6250 ppm toluene resulted in impaired performance in tests designed to measure neuromuscular performance. Daily 15 minute exposure to toluene for up to 4 weeks resulted in a dose-related increase on righting-reflex latency time. A decline in the ability of animals to perform trained neuromuscular responses was also seen following exposure of rats to 125-500 ppm toluene for 4 hours. In this case, recovery occurred in about 2 hours (ATSDR 1993).

V. ENVIRONMENTAL EFFECTS

A. Toxicity to Aquatic Organisms

Toluene has moderate acute toxicity to aquatic organisms; several toxicity values are in the range of greater than 1 mg/L and 100 mg/L. Ninety-six-hour LC50 values for fish are: 12.6-72.0 mg/L for Pimephales promelas (fathead minnow), 13-24 mg/L for Lepomis macrochirus (bluegill), 28.2-59.3 mg/L for Poecilia reticulata (guppy), 240 mg/L for Ictalurus punctatus (channel catfish), and 22.8-57.68 g/L for Carassius auratus (goldfish) (AQUIRE 1994). Ninety-six-hour LC50 values for crustaceans are: 9.5 ppm for Palaemonetes pugio (grass shrimp), 28 ppm for Cancer magister (crab larvae stage 1), 4.3 ppm for Crangon franciscorum (shrimp),

and 9.5 mg/L for Palaemonetes pugio (daggerblade grass shrimp) (AQUIRE 1994). The EC50 values for various parameters in algae are: 245 mg/L, growth, 24 hours for Chlorella vulgaris (green algae); 20 mg/L, photosynthesis effect, 8 hours for Skeletonema costatum (diatom); and 12.5 mg/L, growth, 72 hours for Selenastrum capricornutum (green algae) (AQUIRE 1994).

B. Toxicity to Terrestrial Organisms

No information was found in the secondary sources searched for terrestrial organism toxicity. The oral LD50 in the rat, 5.3-5.9 g/kg), suggests that the chemical would not be acutely toxic to terrestrial animals unless present in very high concentrations. Studies in laboratory animals also suggest that toluene would not cause developmental/reproductive effects in terrestrial species at expected environmental levels (see section IV.F).

C. Abiotic Effects

No information on abiotic effects of toluene was located in the secondary references. According to the definition provided in the Federal Register (1992), toluene is a volatile organic compound (VOC) substance. As a VOC, toluene can contribute to the formation of photochemical smog in the presence of other VOCs.

VI. EPA/OTHER FEDERAL/OTHER GROUP ACTIVITY

Voluntary reduction of toluene environmental releases has occurred since 1991, as a result of a joint industry/EPA pollution prevention initiative, the 33/50 program. The Clean Air Act Amendments of 1990 list toluene as a hazardous air pollutant. Occupational exposure to toluene is regulated by the Occupational Safety and Health Administration (OSHA). The permissible exposure limit (PEL) is 200 parts per million parts of air (ppm) as an 8-hour time-weighted average (TWA) (29 CFR 1910.1000).

Federal agencies and other groups that can provide additional information on toluene are listed in Tables 3 and 4.

VII. END NOTES

1. Standard Industrial Classification code is the statistical classification standard for all Federal economic statistics. The code provides a convenient way to reference economic data on industries of interest to the researcher. SIC codes presented here are not intended to be an exhaustive listing; rather, the codes listed should provide an indication of where a chemical may be most likely to be found in commerce.

TYPES OF HAZARD/ EXPOSURE	ACUTE HAZARDS/ SYMPTOMS	PREVENTION	FIRST AID/ FIRE FIGHTING
FIRE	Highly flammable.	NO open flames, NO sparks, and NO smoking.	Powder, AFFF, foam, carbon dioxide.
EXPLOSION	Vapour/air mixtures are explosive.	Closed system, ventilation, explosion-proof electrical equipment and lighting. Prevent build-up of electrostatic charges (e.g., by grounding). Do NOT use compressed air for filling, discharging, or handling.	In case of fire: keep drums, etc., cool by spraying with water.
EXPOSURE		STRICT HYGIENE! AVOID EXPOSURE OF (PREGNANT) WOMEN!	
• **INHALATION**	Dizziness. Drowsiness. Headache. Nausea. Unconsciousness.	Ventilation, local exhaust, or breathing protection.	Fresh air, rest. Artificial respiration if indicated. Refer for medical attention.
• **SKIN**	Dry skin. Redness.	Protective gloves.	Remove contaminated clothes. Rinse and then wash skin with water and soap. Refer for medical attention.

• **EYES**	Redness. Pain.	Safety goggles or face shield.	First rinse with plenty of water for several minutes (remove contact lenses if easily possible), then take to a doctor.
• **INGESTION**	Abdominal pain. Burning sensation (further see Inhalation).	Do not eat, drink, or smoke during work.	Rinse mouth. Give a slurry of activated charcoal in water to drink. Do NOT induce vomiting. Refer for medical attention.

SPILLAGE DISPOSAL	STORAGE	PACKAGING & LABELLING
Collect leaking liquid in sealable containers. Absorb remaining liquid in sand or inert absorbent and remove to safe place. Do NOT wash away into sewer (extra personal protection: self-contained breathing apparatus).	Fireproof. Separated from strong oxidants. International Chemical Safety Cards

TOLUENE

ICSC: 0078

IMPORTANT

PHYSICAL STATE; APPEARANCE:
COLOURLESS LIQUID , WITH CHARACTERISTIC ODOUR.

PHYSICAL DANGERS:
The vapour is heavier than air and may travel along the ground; distant ignition possible. As a result of flow, agitation, etc., electrostatic charges can be generated.

CHEMICAL DANGERS:
Reacts violently with strong oxidants causing fire and explosion hazard.

OCCUPATIONAL EXPOSURE LIMITS (OELs):
TLV: 50 ppm; 188 mg/m^3 (as TWA) (skin) (ACGIH 1993-1994).
OSHA PEL: TWA 200 ppm C 300 ppm 500 ppm (10-minute maximum peak)
NIOSH REL: TWA 100 ppm (375 mg/m^3) ST

ROUTES OF EXPOSURE:
The substance can be absorbed into the body by inhalation, through the skin and by ingestion.

INHALATION RISK:
A harmful contamination of the air can be reached rather quickly on evaporation of this substance at 20°C.

EFFECTS OF SHORT-TERM EXPOSURE:
The substance irritates the eyes and the respiratory tract. Exposure could cause central nervous system depression. Exposure at high levels may result in cardiac dysrhythmia, unconsciousness and death.

EFFECTS OF LONG-TERM OR REPEATED EXPOSURE:
Repeated or prolonged contact with skin may

D A T A	150 ppm (560 mg/m^3) NIOSH IDLH: 500 ppm	cause dermatitis. The substance may have effects on the central nervous system , resulting in decreased learning ability and psychological disorders. Animal tests show that this substance possibly causes toxic effects upon human reproduction.
PHYSICAL PROPERTIES	Boiling point: 111°C Melting point: -95°C Relative density (water = 1): 0.87 Solubility in water: none Vapour pressure, kPa at 20°C: 2.9 Relative vapour density (air = 1): 3.2	Relative density of the vapour/air-mixture at 20°C (air = 1): 1.06 Flash point: 4°C c.c.°C Auto-ignition temperature: 480°C Explosive limits, vol% in air: 1.1-7.1 Octanol/water partition coefficient as log Pow: 2.69

-PHYSICAL CHEMICAL DATA
 ======================

*PHYSICAL DESCRIPTION: LITERATURE: Clear, colorless to amber liquid
                       REPOSITORY: Clear colorless liquid

*MOLECULAR WEIGHT: 92.14

*SPECIFIC GRAVITY: 0.8669 @ 20/4 C [017,047,430]

*DENSITY: 0.867 g/mL [269,275]

*MP (DEG C): -95 C [205,371,421,430]

*BP (DEG C): 110.6 C [025,051,205,371]

*SOLUBILITIES:
       WATER : <1 mg/mL @ 18 C (RAD)

        DMSO : >=100 mg/mL @ 18 C (RAD)

 95% ETHANOL : >=100 mg/mL @ 18 C (RAD)

    METHANOL : Not available

ACETONE : >=100 mg/mL @ 18 C (RAD)

TOLUENE : Not available

OTHER SOLVENTS:
Alcohol: Soluble [017,053,062,430]
Organic solvents: Miscible [295,421]
Ligroin: Soluble [017]
Chloroform: Miscible [033,043,051,205]
Glacial acetic acid: Miscible [033,051,295]
Carbon disulfide: Miscible [033,051]
Ether: Miscible [033,043,051,205]
Benzene: Soluble [017,053,062]

*VOLATILITY:
Vapor pressure: 10 mm Hg @ 6.4 C, 20 mm Hg @ 18.4 C, 40 mm Hg @ 31.8 C [038]
Vapor density : 3.14 [043,051,071,102]

*FLAMMABILITY(FLASH POINT):
This chemical has a flash point of 4.4 C (40 F) [033,043,421,430]. It is flammable. Fires involving this material can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. A water spray may also be used [051,071]. Vapor trail flash-back can occur [371,451]. The autoignition temperature for this compound is 536 C (997 F) [036,062,371].

*UEL: 7.1% [051,058,421,451] LEL: 1.27% [043,058,102,371]

*REACTIVITY:
This compound reacts violently with 1,3-dichloro-5,5-dimethyl-2,4-imidazolididione, dinitrogen tetraoxide, concentrated nitric acid, (H_2SO_4 + NO_3), $AgClO_4$, BrF_3, UF_6, tetranitromethane and oxidizing materials [043]. It is incompatible with oxygen [058]. It may attack some forms of plastics, rubber and coatings [102].

*STABILITY:
This compound is hygroscopic [269]. Solutions of this chemical in water, DMSO, 95% ethanol or acetone should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Refractive index: 1.4968 @ 20 C [269,275]
Boiling point: 14.5 C @ 14.5 mm Hg [017]
Benzene-like odor [033,062,346,430]
Critical temperature: 318.6 C [371]
Critical pressure: 30400 mm Hg [371]
Floats on water [051,071,371,451]
Dissolves slowly in water [051,071,371]
100% Volatile by volume [058]
Evaporation rate (butyl acetate = 1): >1 [058]
Vapors are heavier than air [058,371]
Burns with a smoky flame [295]
Odor threshold: 0.17 ppm [371]
Burning rate: 5.7 mm/min [371]
Liquid surface tension: 29 dynes/cm @ 20 C [371]
log P octanol: 2.69 @ 20 C [055]
Liquid water interfacial tension: 36.1 dynes/cm [371]
Latent heat of vaporization: 86.1 cal/g [371]
Heat of combustion: -9686 cal/g [371]
Heat of fusion: 17.17 cal/g [371]
Lambda max (in methanol): 269 nm, 265 nm (shoulder), 262 nm, 260 nm (shoulder), 256 nm, 254 nm (shoulder), 249 nm (shoulder), 243 nm (shoulder),

238 nm (shoulder) (epsilon = 227.1, 169.5, 254.6, 212.6, 190.2, 178.2, 125.6, 72.63, 38.8) [052]

*SAX TOXICITY EVALUATION:
THR: Poison by intraperitoneal route. Moderately toxic by intravenous, subcutaneous and possibly other routes. Mildly toxic by inhalation. An experimental teratogen. Human systemic effects by inhalation. Experimental reproductive effects. Mutagenic data. A human eye irritant. An experimental skin and severe eye irritant. In the few cases of acute poisoning reported, the effect has been that of a narcotic, the workman passing through a stage of intoxication into one of coma. Recovery following removal from exposure has been the rule. A common air contaminant.

*CARCINOGENICITY:
Review: IARC Cancer Review: Human Inadequate Evidence
IARC Cancer Review: Animal Inadequate Evidence
IARC: Not classifiable as a human carcinogen (Group 3) [610]
Status: NTP Carcinogenesis Studies (Inhalation); No Evidence: Male and Female Rat, Male and Female Mouse [620]

-OTHER DATA (Regulatory)
==========

*PROPER SHIPPING NAME (IATA): Toluene

*UN/ID NUMBER: UN1294

*HAZARD CLASS: 3 SUBSIDIARY RISK: None PACKING GROUP: II

*LABELS REQUIRED: Flammable liquid

*PACKAGING: PASSENGER: PKG. INSTR.: 305, Y305 MAXIMUM QUANTITY: 5 L, 1 L
CARGO : PKG. INSTR.: 307 MAXIMUM QUANTITY: 60 L

*SPECIAL PROVISIONS: None

*USES:
This compound is used to manufacture benzoic acid, benzaldehyde, benzene, phenol, caprolactam, linoleum, toluenediisocyanates (polyurethane resins),

toluene sulfonates (detergents), artificial leather and fabric and paper coatings. It is also used in explosives, dyes and other organic compounds, as a solvent for paints, lacquers, gums, most oils, rubber, vinyl organosols and resins, in the extraction of various principles of plants, as a gasoline additive, as a diluent and thinner in nitrocellulose lacquers, as an adhesive solvent in plastic toys and model airplanes, in saccharin, perfumes and scintillation counters, in photogravure color-printing process, in the cleaning industry, in the impregnation of cartridge paper, as a solvent in pharmaceutical and plastic industries, as an insecticide, as a urine preservative for chemical examination and as an asphalt and naphtha constituent.

*COMMENTS:
This compound is obtained from coal tar and petroleum [055,421].

-HANDLING PROCEDURES
==========

*ACUTE/CHRONIC HAZARDS:
This compound may cause irritation of the respiratory tract, mucous membranes and throat [051]. It may also cause eye and skin irritation [053, 058,102,346]. It may be harmful by inhalation, ingestion or skin absorption [036,051,071,269]. It is readily absorbed through the skin [269]. When heated to decomposition it emits toxic fumes of carbon dioxide and carbon monoxide [102,269].

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS:
GlovES+ Expert System Glove Types For The Neat (Undiluted) Chemical:
This chemical has not been tested for permeation by Radian Corporation; however, the GlovES+ expert system was used to extrapolate permeation test information from compounds in the same chemical class. The GlovES+ system uses permeation data from literature sources; therefore, extra safety margins should be used with the estimated protection time(s). If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.
The GlovES+ expert system is a tool that can help people better manage protection from chemicals, however this tool cannot replace sound judgment nor make technical decisions. Our GlovES+ expert system is designed to offer initial advice and assistance in glove selection while the final glove selection should be made by knowledgeable individuals based on the specific circumstances involved.

Glove Type	Model Number	Thickness	Estimated Protection Time
PE/EVAL/PE	Safety 4 4H	0.07 mm	240 min
PVA	Edmont 25-545	unknown	360 min
Unknown	North Silvershield	0.08 mm	360 min
Viton	North F-091	0.24 mm	480 min

Permeation Test Results of Diluted Chemical in corn oil (50%):
The permeation test results for solutions of this chemical are given below. The breakthrough times of the diluted chemicals at the given concentration are given for each glove type tested. The table is a presentation of actual test results, not specific recommendations or suggestions. Avoid glove types which exhibit breakthrough times of less than the anticipated task time plus an adequate safety factor. If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.

Glove Type	Model Number	Thickness	Breakthrough Time

Nitrile	Edmont 37-175	0.64 mm	98 min
Butyl Rubber	North B-174	0.38 mm	46 min
PVA	Edmont 29-250	0.46 mm	6 min

*RECOMMENDED RESPIRATOR:
Where the neat test chemical is weighed and diluted, wear a NIOSH-approved half face respirator equipped with an organic vapor/acid gas cartridge (specific for organic vapors, HCl, acid gas and SO2) with a dust/mist filter.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should store this chemical in an explosion-proof refrigerator and keep it away from moisture. If possible, it would be prudent to store this compound under inert atmosphere. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you spill this chemical, FIRST REMOVE ALL SOURCES OF IGNITION. Then, use absorbent paper to pick up all liquid spill material. Your contaminated clothing and absorbent paper should be sealed in a vapor-tight plastic bag for eventual disposal. Solvent wash all contaminated surfaces with 60-70% ethanol followed by washing with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT: Not available

-EMERGENCY PROCEDURES
==========

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a

hospital or poison control center. Be prepared to transport the victim to a hospital if advised by a physician.

If the victim is convulsing or unconscious, do not give anything by mouth, ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport the victim to a hospital.

*SYMPTOMS:

Symptoms of exposure to this compound include eye irritation, dilation of the pupils, impairment of reaction in association with fatigue, slight pallor of the fundi, inebriation, ocular disturbances and reddening of vision [099]. It may cause dizziness, headache, nausea, mental confusion, blood disease and dermatitis [036]. It may also cause giddiness [071]. Other symptoms may include hallucinations or distorted perceptions, narcosis in high concentrations, motor activity changes. An occasional report of chronic poisoning describes an anemia and leucopenia. It causes loss of appetite, a bad taste, lassitude, impairment of coordination and reaction time and an enlarged liver [043]. It may cause central nervous system depression, bone marrow depression, petechial hemorrhages, noncoagulated blood, congestion of all organs, severe bone marrow aplasia, necrosis or fatty degeneration of the heart, liver and adrenals, weakness, euphoria, vomiting, tightness in the chest, blurred vision, tremors, shallow and rapid respiration, ventricular irregularities including fibrillation, paralysis, convulsions, violent excitement or delirium, unconsciousnes, kidney or liver damage, skin irritation, scaling and cracking, drowsiness, nervousness, pallor, petechiae, abnormal bleeding, irreversible encephalopathy with ataxia, tremulousness, emotional lability, diffuse cerebral atrophy and death [301]. It may also cause abnormal tendon reflexes, reduced grasping power, decreased finger agility, metabolic acidosis, hepatomegaly, exhilaration, lightheadedness, cardiovascular collapse, cardiac arrhythmias, bradycardia, mydrasis, insomnia, restlessness, staggering gait, lack of self-control, stupor, increased irritability (personality changes), exaggerated mood swings, equilibrium disorders and vertigo [051]. Symptoms of exposure may include skin sensation such as a pins and needles feeling or numbness and difficulty in seeing bright light [102]. It may cause high urinary pH, nightmares, vertical nystagmus and status epilepticus [295]. It may also cause loss of memory, anorexia, palpitation and aplastic anemia [421]. Other symptoms include renal but also neural and especially cerebellar dystrophy, lacrimation, hilarity, nasal mucous secretion and metallic taste. High concentrations may result in paresthesia, collapse, cardiac sensitization and fatal cardiotoxicity [430]. It may cause irritation to the nose and throat, respiratory arrest, coughing, gagging, distress, pulmonary edema, griping and diarrhea [371]. It may also cause chemical pneumonitis, coma and conjunctivitis [058].

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

XYLENE (MIXED ISOMERS) (1330-20-7)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards**

  Recognized: --

Suspected:		Reference(s)
	Cardiovascular or Blood Toxicant	EPA-HEN RTECS
	Developmental Toxicant	EPA-HEN EPA-SARA JANK
	Gastrointestinal or Liver Toxicant	EPA-HEN RTECS
	Immunotoxicant	IPCS
	Neurotoxicant	DAN EPA-HEN OEHHA-2000 RTECS
	Reproductive Toxicant	EPA-SARA
	Respiratory Toxicant	EPA-HEN LU OEHHA-2000 OEHHA-AREL RTECS
	Skin or Sense Organ Toxicant	EPA-HEN OEHHA-AREL RTECS

- **Hazard Rankings**

  More hazardous than most chemicals in 3 out of 10 ranking systems.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.
  Used in at least 12 industries.
  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.
  Used in pesticide products.

- **Profile of Environmental Release and Waste Generation**

  For a list of the geographic areas, facilities, or industrial sectors which report the largest releases or transfers of this chemical to the Toxics Release Inventory, select what you want:

  - Rank States
  - Rank Counties
  - Rank Zip Codes
  - Rank Facilities
  - Rank Industrial Sectors

- **Regulatory Coverage**

  On at least 6 federal regulatory lists.

- **Basic Testing to Identify Chemical Hazards**

Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

- **Information Needed for Safety Assessment**

  Lacks at least some of the national data required for safety assessment.
  Scorecard has risk assessment data for this chemical.

- **Links**

  Additional information about this chemical may be available elsewhere in Scorecard.

  Other web sites specific to this chemical:

  - Agency for Toxic Substances and Disease Registry Public Health Statement
  - Agency for Toxic Substances and Disease Registry ToxFAQ
  - CalEPA Air Resources Board Toxic Air Contaminant Summary
  - EPA Health Effects Notebook for Hazardous Air Pollutants

Consumer Products

that contain XYLENE (MIXED ISOMERS) (1330-20-7) from Scorecard

---

What kinds of consumer products may contain this chemical?

- Aerosol paint concentrates
- Agricultural chemicals
- Architectural coatings
- Auto, other transportation, and machinery refinish paints incl primers
- Automobile body polish and cleaners
- Caulks, modified and unmodified oil base
- Cooling tower compounds
- Epoxy adhesives
- Floor polish
- Fungicides for agric., garden and health service use
- General performance sealants (PVAC, butyl, vinyl, etc.)
- Ground/traffic marking coatings
- Herbicides for agric., garden and health service use
- Household hard surface cleaners (aerosol)
- Household hard surface cleaners (liquid)
- Household pesticides
- Industrial interior coatings
- Industrial particleboard (furniture, fixtures, cabinets, etc.)
- Insecticides for agric., garden and health service use
- Insecticides for crawling insects
- Insecticides for flying insects
- Lubricating oils
- Markers, fine point and broad tipped
- Misc. use aromatics
- Miscellaneous agricultural/pesticidal products
- Miscellaneous paint-related products
- Nonstructural caulking compounds and sealants
- Other art materials incl clay, water & tempera colors, finger paint, etc.
- Other automotive chemicals
- Other laundry aids, icluding ironing aids and dry cleaning spotting pre
- Other miscellaneous allied paint products, including brush cleaners
- Other nonhousehold pesticides

- Other polishing preparations and related products
- Other specialty cleaning and sanitation products
- Paint and varnish removers
- Paint thinners
- Paints and allied products
- Pet flea and tick products, including collars
- Preformed tapes (butyl, polybutene, polyisobutylene, etc.)
- Rodenticides
- Rubber and synthetic resin combinations
- Shoe polishes and cleaners
- Solvent thinned exterior stains incl shingle and shake
- Solvent thinned exterior undercoaters and primers
- Solvent thinned interior clear finishes
- Solvent thinned interior stains
- Solvent thinned interior undercoaters and primers
- Specialty performance sealants
- Synthetic resin and rubber adhesives
- Textile finishes
- Thick line coloring pens and markers
- Waterproofing compounds
- Wood office work surfaces (modular systems)

Basic Testing to Identify Chemical Hazards

for XYLENE (MIXED ISOMERS) (1330-20-7) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

More on the importance of basic toxicity testing

Agency for Toxic Substances and Disease Registry

Public Health Statement

Xylene

ATSDR Public Health Statement, December 1990

This Statement was prepared to give you information about xylene and to emphasize the human health effects that may result from exposure to it. The Environmental Protection Agency (EPA) has identified 1,177 sites on its National Priorities List (NPL). Xylene has been found at 236 of these sites. However, we do not know how many of the 1,177 NPL sites have been evaluated for xylene. As EPA evaluates more sites, the number of sites at which xylene is found may change. The information is important for you because xylene may cause harmful health effects and because these sites are potential or actual sources of human exposure to xylene.

When a chemical is released from a large area such as an industrial plant, or from a container, such as a drum or bottle, it enters the environment as a chemical emission. This emission, which is also called a release, does not always lead to exposure. You can be exposed to a chemical only when you come into contact with the chemical. You may be exposed to it in the environment by breathing, eating, or drinking substances containing the chemical or from skin contact with it.

If you are exposed to a hazardous substance such as xylene, several factors will determine whether harmful health effects will occur and what the type and severity of those health effects will be. These factors include the dose (how much), the duration (how long), the route or pathway by which you are exposed (breathing, eating, drinking, or skin contact), the other chemicals to which you are exposed, and your individual characteristics such as age, sex, nutritional status, family traits, life style, and state of health.

What is xylene?

Xylene is primarily a man-made chemical. Chemical industries produce xylene from petroleum and to a smaller extent from coal. Xylene also occurs naturally in petroleum and coal tar, and is formed during forest fires. It is a colorless liquid with a sweet odor. There are three forms of xylene called isomers: *meta*-xylene, *ortho*-xylene, and *para*-xylene (*m*-, *o*- and *p*-xylene). Mixed xylene is a mixture of the three forms of xylene and smaller amounts of other chemicals, primarily ethylbenzene. Mixed xylene usually contains 6%-15% ethylbenzene, although it may contain higher amounts. The term "total xylenes," as

used in the title of this report, refers to the three forms or isomers of xylene (*meta-*, *ortho-* , and *para*-xylene) and also to mixed xylene. In this public health statement, the term "total xylenes" and xylene will be used interchangeably.

Solvents (liquids that can dissolve solids) and thinners for paints and varnishes often contain xylene, along with other solvents. Xylene is used as a solvent in the printing, rubber, and leather industries, and as a cleaning agent. It is also found in airplane fuel and gasoline, and is used as a material in the chemical, plastic, and synthetic fiber industries, and as an ingredient in the coating of fabrics and papers. Isomers of xylene are used in the manufacture of certain polymers, such as plastics.

Xylene evaporates and burns easily. Xylene does not mix well with water; however, it does mix with alcohol and with many other chemicals. Xylene is a liquid, and it can leak into soil, surface water (creeks, streams, rivers), or groundwater, where it may remain for 6 months or longer before it is broken down into other chemicals. However, because it evaporates readily, most xylene goes into the air, where it lasts for several days. During these several days in the air, the xylene is broken down by sunlight into other kinds of chemicals.

How might I be exposed to xylene?

You may become exposed to xylene because of its wide distribution in the environment. Releases of xylene occur primarily from industrial sources, automobile exhaust, and from the use of xylene as a solvent. Hazardous waste disposal sites and spills of xylene into the environment also serve as possible sources of exposure. Levels of xylene measured in industrial areas and cities of the United States and Europe range between 0.0007 and 0.09 parts of xylene per million parts of air (ppm). Xylene is sometimes released into water and soil as a result of the use, storage, and transport of petroleum products. Surface water generally contains less than 1 part of xylene per billion parts of water (ppb), although the level may be higher in industrial areas. Levels of xylene in public drinking water supplies range from 0 to 750 ppb. Because xylene evaporates rapidly, the presence of xylene in upper layers of soil is probably not large. Little information exists about the amount of xylene in food. Levels ranging between 0.05 ppm and 0.12 ppm xylene have been found in fish.

You may also come in contact with xylene from a variety of consumer products, including cigarette smoke, gasoline, paint, varnish, shellac, and rust preventives. Breathing vapors from these types of products can expose you to xylene. Indoor levels of xylene can be higher than outdoor levels, especially in buildings with poor ventilation. Skin contact with products containing xylene, such as solvents, lacquers, paint thinners and removers, and pesticides may also expose you to xylene.

In addition to painters (or paint industry workers), biomedical laboratory workers, distillers of xylene, wood processing plant workers, garage workers, metal workers, and furniture refinishers also may be exposed to xylene. Exposure to high levels of xylene is most likely to occur in workers who smoke and routinely come in contact with solvent products.

How can xylene enter and leave my body?

Xylene is most likely to enter your body through breathing xylene vapors. Less often, xylene enters the body through the skin following direct contact. Exposure to xylene may also take place by eating or drinking xylene- contaminated food or water. Xylene is rapidly absorbed by the lungs following breathing air containing xylene. The amount of xylene retained by the lungs ranges from 50% to 75% of the amount of xylene to which you are exposed. Physical exercise increases the amount of xylene absorbed by the lungs. Absorption of xylene after eating food or drinking water containing it is both rapid and complete. Absorption of xylene through the skin also occurs rapidly following direct contact with xylene or exposure to xylene vapors in the air. At hazardous waste sites, breathing xylene vapors, drinking wellwater contaminated with xylene, and direct contact of the skin with xylene are possible ways you can be exposed. Xylene passes into the blood soon after entering the body.

In humans and laboratory animals, xylene is broken down into other chemicals in the liver and lungs. This process changes most of the xylene that is breathed in or swallowed into a different form. Once xylene has been broken down, the breakdown products rapidly leave the body, mainly in urine but some unchanged xylene also leaves in breath from the lungs. Small amounts of broken down xylene have appeared in urine of humans as soon as 2 hours after breathing air containing xylene. Usually most of the xylene that is taken in leaves the body within 18 hours after exposure ends. Storage of xylene in fat or muscle may prolong the time needed for xylene to leave the body.

How can xylene affect my health?

Short-term exposure of humans to high levels of xylene or chemical mixtures containing xylene causes irritation of the skin, eyes, nose, and throat; difficulty in breathing; impaired function of the lungs; delayed response to a visual stimulus; impaired memory; stomach discomfort; and possible changes in the liver and kidneys. Death can occur in individuals who are exposed to very high levels of xylene for a short period of time. Both short- and long-term exposure to high concentrations of xylene can also cause a number of effects on the nervous system, such as headaches, lack of muscle coordination, dizziness, confusion, and changes in one's sense of balance.

Results of studies with animals indicate that large amounts of xylene can cause changes in the liver and adverse effects on the kidney, lung, heart, and nervous system. Short-term exposure to high concentrations of xylene causes death in some animals, as well as muscular spasms, incoordination, hearing loss, changes in behavior, changes in organ weights, and changes in enzyme activity. Long-term exposure to low concentrations of xylene has not been well studied in animals.

Information from animal studies is not adequate to determine whether or not xylene causes cancer in humans. The International Agency for Research on Cancer has determined that xylene is not classifiable as to its carcinogenicity to humans. However, exposure of pregnant women to high levels of xylene may cause adverse effects in the fetus. Studies with unborn animals indicate that high levels of xylene may cause increased numbers of deaths, decreased weight, skeletal changes, and delayed skeletal development. In many instances, the levels of xylenes causing these effects also caused the mothers to be ill. The higher the level of exposure and the longer the exposure to xylene, the greater the chance for adverse health effects.

What levels of exposure have resulted in harmful health effects?

Xylene or chemical mixtures containing xylene are deadly to humans if large enough quantities are swallowed or inhaled. However, the levels which cause death in humans are not known. Lower levels (100-299 ppm) of inhaled xylene can cause eye, nose, and throat irritation, delayed response to a visual stimulus, and poor memory. Direct contact of humans with several drops of xylene causes skin irritation. The lowest level at which you can detect the odor of xylene in air ranges from 0.1 ppm to 2.0 ppm.

In animals, moderate to high levels (1,300-2,000 ppm) of xylene inhaled for short periods of time may cause decreased breathing rate, hearing loss, inactivity, unconsciousness, and biochemical changes in the brain. With longer-term inhalation, adverse health effects in animals generally occur at lower levels (230-800 ppm). In animals breathing high levels of xylene over long-term exposures, possible adverse health effects include changes in heart rate and blood flow, changes in the chemical composition of nerves, and hearing loss. In animals given high levels (5,000 ppm) of xylene orally over short-term exposures, a possible adverse health effect is impaired eye function. In animals exposed by mouth to very high levels (40,000 ppm) of xylene, death can occur.

Tables 1-1, 1-2, 1-3, and 1-4 show the relationship between exposure to xylene and known health effects.

Is there a medical test to determine whether I have been exposed to xylene?

Medical tests are available to determine if you have been exposed to xylene at greater than normal background levels. Confirmation of xylene exposure is determined by measuring xylene's breakdown products that are eliminated from the body in the urine. These urinary measurements will specifically determine if you have been exposed to xylene. There is a high degree of agreement between exposure to xylene and the levels of xylene's breakdown products in the urine. A urine sample must be provided soon after exposure ends, because xylene quickly leaves the body. Alcohol and aspirin may affect the test results. Available tests can only indicate exposure to xylene; they cannot be used to predict which health effects, if any, will develop.

What recommendations has the federal government made to protect human health?

The U.S. Environmental Protection Agency (EPA) estimates that for an adult of average weight, exposure to 0.4 milligrams of xylene per liter (mg/L or ppm) of water each day for a lifetime (70 years) is unlikely to result in noncancerous adverse health effects. For a long-term, but less than lifetime, exposure (about 7 years), 27.3 ppm is estimated to be a level unlikely to result in noncancerous adverse health effects for an adult. Exposure to 12 ppm of xylene in water for 1 day or to 7.8 ppm of xylene in water for 10 days or longer is unlikely to present a noncancerous health risk to a small child. EPA has proposed a recommended maximum level of 0.44 ppm for xylene in drinking water.

To protect individuals from the potential adverse health effects of xylene, the federal government regulates xylene in the environment. The Occupational Safety and Health Administration (OSHA) has set up a legally enforceable occupational exposure limit of 100 ppm of xylene in air averaged over an 8-hour workday, and a 15- minute exposure limit of 150 ppm. The National Institute for Occupational Safety and Health (NIOSH) has recommended an exposure limit of 100 ppm of xylene averaged over a workday up to 10 hours long in a 40-hour workweek. NIOSH has also recommended that exposure to xylene not exceed 200 ppm for longer than 15 minutes. NIOSH has classified xylene exposures of 10,000 ppm as immediately dangerous to life or health.

EPA and the Food and Drug Administration (FDA) specify conditions under which xylene may be used as a part of herbicides, pesticides, or articles that are used in contact with food.

EPA reportable quantity regulations require that a spill of 1,000 pounds or more of xylene or used xylene solvents be reported to the Federal Government National Response Center.

Where can I get more information?

If you have any more questions or concerns not covered here, please contact your state health or environmental department or:

```
Agency for Toxic Substances and Disease Registry
Division of Toxicology
1600 Clifton Road, E-29
Atlanta, Georgia 30333
```

This agency can also give you information on the location of the nearest occupational and environmental health clinics. Such clinics specialize in recognizing, evaluating, and treating illnesses that result from exposure to hazardous substances.

Material Safety Data Sheet
(University of Utah)

Agency for Toxic Substances and Disease Registry

This fact sheet answers the most frequently asked health questions about xylene. For more information, you may call the ATSDR Information Center at 1-800-447-1544. This fact sheet is one in a series of summaries about hazardous substances and their health effects. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present. It's important you understand this information because this substance may harm you; refer to the glossary for definitions of any technical words.

SUMMARY: Exposure to xylene occurs in the workplace and when you use paint, gasoline, paint thinners and other products that contain it. People who breathe high levels may have dizziness, confusion, and a change in their sense of balance. This substance has been found in at least 658 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is xylene?
(Pronounced zy'leen)

Xylene is a colorless, sweet-smelling liquid that catches on fire easily. It occurs naturally in petroleum

and coal tar and is formed during forest fires. You can smell xylene in air at 0.08-3.7 parts of xylene per million parts of air (ppm) and begin to taste it in water at 0.53-1.8 ppm.

Chemical industries produce xylene from petroleum. It's one of the top 30 chemicals produced in the United States in terms of volume.

Xylene is used as a solvent and in the printing, rubber, and leather industries. It is also used as a cleaning agent, a thinner for paint, and in paints and varnishes. It is found in small amounts in airplane fuel and gasoline.

What happens to xylene when it enters the environment?

- Xylene has been found in waste sites and landfills when discarded as used solvent, or in varnish, paint, or paint thinners.
- It evaporates quickly from the soil and surface water into the air.
- In the air, it is broken down by sunlight into other less harmful chemicals.
- It is broken down by microorganisms in soil and water.
- Only a small amount of it builds up in fish, shellfish, plants, and animals living in xylene-contaminated water.

How might I be exposed to xylene?

- Breathing xylene in workplace air or in automobile exhaust.
- Breathing contaminated air.
- Touching gasoline, paint, paint removers, varnish, shellac, and rust preventatives that contain it.
- Breathing cigarette smoke that has small amounts of xylene in it.
- Drinking contaminated water or breathing air near waste sites and landfills that contain xylene.
- The amount of xylene in food is likely to be low.

How can xylene affect my health?

Xylene affects the brain. High levels from exposure for **short periods** (14 days or less) or **long periods** (more than 1 year) can cause headaches, lack of muscle coordination, dizziness, confusion, and changes in one's sense of balance. Exposure of people to **high levels** of xylene for **short periods** can also cause irritation of the skin, eyes, nose, and throat; difficulty in breathing; problems with the lungs; delayed reaction time; memory difficulties; stomach discomfort; and possibly changes in the liver and kidneys. It can cause unconsciousness and even death at **very high levels**.

Studies of unborn animals indicate that **high concentrations** of xylene may cause increased numbers of deaths, and delayed growth and development. In many instances, these same concentrations also cause damage to the mothers. We do not know if xylene harms the unborn child if the mother is exposed to **low levels** of xylene during pregnancy.

How likely is xylene to cause cancer?

The **International Agency for Research on Cancer (IARC)** has determined that xylene is not classifiable as to its carcinogenicity in humans.

Human and animal studies have not shown xylene to be carcinogenic, but these studies are not

conclusive and do not provide enough information to conclude that xylene does not cause cancer.

Is there a medical test to show whether I've been exposed to xylene?

Laboratory tests can detect xylene or its breakdown products in exhaled air, blood, or urine. There is a high degree of agreement between the levels of exposure to xylene and the levels of xylene breakdown products in the urine. However, a urine sample must be provided very soon after exposure ends because xylene quickly leaves the body. These tests are not routinely available at your doctor's office.

Has the federal government made recommendations to protect human health?

The **EPA** has set a limit of 10 ppm of xylene in drinking water.

The **EPA** requires that spills or accidental releases of xylenes into the environment of 1,000 pounds or more must be reported.

The **Occupational Safety and Health Administration (OSHA)** has set a maximum level of 100 ppm xylene in workplace air for an 8-hour workday, 40-hour workweek.

The **National Institute for Occupational Safety and Health (NIOSH)** and the **American Conference of Governmental Industrial Hygienists (ACGIH)** also recommend exposure limits of 100 ppm in workplace air.

NIOSH has recommended that 900 ppm of xylene be considered immediately dangerous to life or health. This is the exposure level of a chemical that is likely to cause permanent health problems or death.

Glossary

Evaporate:

To change from a liquid into a vapor or a gas.

Carcinogenic:

Having the ability to cause cancer.

CAS:

Chemical Abstract Service.

PPM:

Parts per million.

Solvent:

A liquid that can dissolve other substances.

XYLENES (Isomers and Mixture)

Xylenes (isomers and mixture) are federal hazardous air pollutants and were identified as toxic air contaminants in April 1993 under AB 2728.

Molecular Formula: C_8H_{10}

This fact sheet refers to the mixture of m-xylene, o-xylene, and p-xylene (mixed xylenes). Mixed xylenes are colorless liquids that are insoluble in water and miscible with alcohol, ether, and many other organic solvents. The commercial mixed xylenes are composed of the three isomers, with the m- and p- isomers predominating. For particular purposes, the m-, o-, or p- isomer may be separated. They are insoluble in water (HSDB, 1991; Sax, 1987).

Physical Properties of Mixed Xylenes

	m-Xylene	o-Xylene	p-Xylene
CAS Registry Number	108-38-3	95-47-6	106-42-3
Molecular Weight	106.18	106.18	106.18
Boiling Point	139.3 °C	144.4 °C	137-138 °C
Melting Point	-47.4 °C	-25.2 °C	13-14 °C
Flash Point	77 °F (closed cup)	62.6 °F	77 °F (closed cup)
Vapor Density	3.66 (air = 1)		3.66 (air=1)
Vapor Pressure	8.3 mm Hg at 25 °C	6.6 mm Hg at 25 °C	8.7 mm Hg at 25 °C
Density/Specific Gravity	0.8684 at 15/4 °C water=1	0.880 at 20/4 °C water=1	0.86104 at 20/4 °C water=1
Log Octanol/WaterPartition Coefficient:	3.20	3.12	3.15
Conversion Factor:	1 ppm = 4.3 mg/m^3	1 ppm = 4.3 mg/m^3	1 ppm = 4.3 mg/m^3

(Howard, 1990; Merck, 1989; Sax, 1987; Sax, 1989)

SOURCES AND EMISSIONS

A. Sources

Emissions of mixed xylenes have been detected from petroleum refining, motor vehicles, residential wood-burning stoves and fireplaces. Mixed xylenes are used as chemical intermediates, as solvents, in aviation fuel, and in household products such as aerosol paints and lacquers (Howard, 1990).

Xylene is registered as an insecticide. Only one product containing xylene is still registered, although use of this product has been suspended since 1993. It was registered for use on fruit, vegetable and grain crops, on ornamental lawns, gardens and plants. It may be applied to dogs, and animal dwellings as well

as around houses and farm buildings (DPR, 1996).

The licensing and regulation of pesticides for sale and use in California are the responsibility of the Department of Pesticide Regulation (DPR). Information presented in this fact sheet regarding the permitted pesticidal uses of xylene has been collected from pesticide labels registered for use in California and from DPR's pesticide databases. This information reflects pesticide use and permitted uses in California as of October 15, 1996. For further information regarding the pesticidal uses of this compound, please contact the Pesticide Registration Branch of DPR (DPR, 1996).

The primary stationary sources that have reported emissions of m-, o-, and p-xylene in California are manufacturers of motor vehicles and equipment, manufacturers of metal cans and shipping containers, and petroleum refining (ARB, 1997b).

B. Emissions

The total emissions of m-, o-, and p-xylene from stationary sources in California are estimated to be at least 30,000 pounds, 34,000 pounds, and 51,000 pounds per year, respectively, based on data reported under the Air Toxics "Hot Spots" Program (AB 2588). In addition, there are also approximately 4 million pounds of unspecified xylenes in addition to those listed individually (ARB, 1997b).

C. Natural Occurrence

m- and p-Xylene occur naturally in petroleum. o-Xylene is found in coal tar, petroleum, forest fires and plant volatiles (Howard, 1990).

AMBIENT CONCENTRATIONS

m-, o-, and p-Xylene are routinely monitored by the statewide Air Resources Board air toxics network. The network's mean concentration of m- and p-xylene from January 1996 through December 1996 is estimated to be 4.17 micrograms per cubic meter ($\mu g/m^3$) or 0.97 parts per billion (ppb). The network's mean concentration of o-xylene, from January 1996 through December 1996, is estimated to be 1.55 µg/m3 or 0.36 ppb (ARB, 1997c).

The United States Environmental Protection Agency (U.S. EPA) has also compiled ambient data from 31 study areas throughout the United States on p-xylene from 1985-87. The U.S. EPA reported an overall p-xylene mean concentration of 8.7 $\mu g/m^3$ or 2.0 ppb. The U.S. EPA has also compiled ambient o- and m-xylene data from three study areas throughout the United States from 1989-91. The U.S. EPA reported an overall o-xylene mean concentration of 2.6 $\mu g/m^3$ or 0.6 ppb and an overall m-xylene mean concentration of 5.4 $\mu g/m^3$ or 1.3 ppb (U.S. EPA, 1993a).

INDOOR SOURCES AND CONCENTRATIONS

m-, o-, and p-Xylene are widely used as solvents and are present in numerous consumer products. Consumer products with the highest median emissions of xylenes include pens/inks and coatings. Xylenes are also emitted from building materials such as carpet adhesives, vinyl cove adhesive, latex

caulk, latex paint, and various moldings. Environmental tobacco smoke is also a common indoor source of xylenes (Hodgson and Wooley, 1991).

Indoor residential concentrations of m-, p-, and o-xylene have been measured in several studies. The California Total Exposure Assessment Methodology (TEAM) studies were conducted in 1984 and 1987 in and around Los Angeles and Contra Costa County. Because of their physical similarities, m-xylene and p-xylene have been reported as a single value. The mean m- and p-xylene concentrations from these studies ranged from 9.3 to 33.6 µg/m^3. The mean o-xylene concentrations from these studies ranged from 3.71 to 12.9 µg/m^3. Indoor values from these studies were consistently higher than outdoor values. The indoor/outdoor ratio was approximately 1.5 to 2.5. (Pelizzari, 1987b; 1989).

In a residential study conducted in Woodland, California m-, p-, and o-xylene were quantifiable in 99 percent of the 125 samples. The indoor average m-, p-xylene concentration was 7.4 µg/m^3 and the values ranged from below the quantifiable level of 0.35 to 120 µg/m^3. The indoor average o-xylene concentration from that study was 3.3 µg/m^3 and the values ranged from below the quantifiable level of 0.1 to 49 µg/m^3. The indoor/outdoor ratio of m-, p-, and o-xylene in this study was 4.6 µg/m3 (Sheldon et al., 1992).

In-vehicle concentrations of m-, p-, and o-xylene were 2 to 6 times higher than outdoor levels. In southern California, a total xylene average concentration of 32.9 µg/m^3 and a maximum concentration of 254 µg/m^3 were measured (Shikiya et al., 1989). In Boston, an average m-, p-xylene of 20.9 µg/m^3 and a maximum of 74.6 µg/m^3 were recorded. The average and maximum concentrations of o-xylene during this study were 7.3 µg/m^3 and 26.1 µg/m^3, respectively (Chan et al., 1991b). Similar results were observed in a Raleigh, North Carolina in-vehicle study (Chan et al., 1991a).

Emissions of m-, p- Xylene averaged 299 µg/cigarette in environmental tobacco smoke in a chamber study of six brands of cigarettes popular in California (Daisey et al., 1994). Emissions of o-xylene averaged 67 µg/cigarette in environmental tobacco smoke.

ATMOSPHERIC PERSISTENCE

The atmospheric lifetime of m-xylene is 14 to 15 hours. The atmospheric lifetime of o-xylene is 25 to 26 hours. The atmospheric lifetime of p-xylene is 24 to 25 hours (Kao, 1994).

The reaction products of m-xylene are m-tolualdehyde, m-methyl benzyl nitrate, nitro-m-xylene, dimethylphenols, formaldehyde, glyoxal, and methyl glyoxal. The reaction products of o-xylene are o-tolualdehyde, o-methyl benzyl nitrate, nitro-o-xylene, dimethylphenols, formaldehyde, glyoxal, methyl glyoxal, and biacetyl. The reaction products of p-xylene are p-tolualdehyde, p-methyl benzyl nitrate, nitro-p-xylene, dimethylphenols, formaldehyde, glyoxal, and methyl glyoxal (Kao, 1994).

AB 2588 RISK ASSESSMENT INFORMATION

The Office of Environmental Health Hazard Assessment reviews risk assessments submitted under the Air Toxics "Hot Spots" Program. Of the risk assessments reviewed as of December 1996, for non-cancer health effects, xylenes contributed to the total hazard index in 46 of the approximately 89 risk

assessments reporting a total chronic hazard index greater than 1. Xylenes also contributed to the total hazard index in 42 of the approximately 107 risk assessments reporting a total acute hazard index greater than 1 (OEHHA, 1996b).

HEALTH EFFECTS

Probable routes of human exposure to xylenes are inhalation, ingestion, and dermal contact (U.S. EPA, 1994a).

Non-Cancer: Exposure to xylene vapors may cause eye, nose, throat, and respiratory tract irritation. Xylene is a central nervous system depressant. Acute exposure may cause gastrointestinal effects such as nausea, vomiting, and gastric irritation. By analogy to toluene and benzene, xylene is predicted to cause cardiac arrythmias. Exposure may injure the kidneys.

An acute non-cancer Reference Exposure Level (REL) of 4.4 x 10^3 µg/m^3 and a chronic non-cancer REL of 3 x 102 µg/m^3 are listed for mixed xylenes in the California Air Pollution Control Officers Association Air Toxics "Hot Spots" Program, Revised 1992 Risk Assessment Guidelines. The toxicological endpoint considered for acute toxicity is respiratory irritation. The toxicological endpoints considered for chronic toxicity are the respiratory system and reproductive system including teratogenic and developmental effects (CAPCOA, 1993). The U.S. EPA is currently reviewing the Reference Concentration (RfC) for mixed xylenes, m-, o-, and p-xylenes. The U.S. EPA has established an oral reference dose (RfD) of 2 milligrams per kilogram per day (mg/kg/d) for mixed xylenes based on hyperactivity, decreased body weight, and increased mortality in rats. The provisional RfD for m- and o-xylenes is also 2 mg/kg/d. The U.S. EPA estimates that consumption of this dose or less, over a lifetime, would not likely result in the occurrence of chronic, non-cancer effects. The U.S. EPA has not established an RfD for p-xylenes (U.S. EPA, 1994a).

In mice, rats, and rabbits, inhalation of mixed xylene or one of o-, m-, or p-xylene has resulted in increased post-implantation loss, reduced fetal weight, and other indications of retarded development. Oral exposure at high levels in mice has produced cleft palate and reduced fetal weight (ATSDR, 1993i; IARC, 1989c; HSDB, 1995).

Cancer: No information is available on the carcinogenic effects of mixed xylenes in humans. The U.S. EPA has classified xylene (isomers and mixtures) in Group D: Not classifiable as a carcinogen (U.S. EPA, 1994a). The International Agency for Research on Cancer has classified xylene (isomers and mixtures) in Group 3: Not classifiable as to carcinogenicity (IARC, 1987a).

XYLENES[(1)]

1330-20-7

Hazard Summary

CAUTION: Unless otherwise noted, the quantitative information on these fact sheets are from "EPA Health Effects Notebook for Hazardous Air Pollutants-Draft", EPA-452/D-95-00, PB95-503579, December 1994." Please conduct a current literature search and check the appropriate current online database for the most recent quantitative information.

- Acute (short-term) inhalation exposure to mixed xylenes in humans results in **irritation of the nose and throat, gastrointestinal effects such as nausea, vomiting, and gastric irritation, mild transient eye irritation, and neurological effects.**
- Chronic (long-term) inhalation exposure of humans to mixed xylenes results primarily in **central nervous system (CNS) effects, such as headache, dizziness, fatigue, tremors and incoordination.** Other effects noted include labored breathing and impaired pulmonary function, increased heart palpitation, severe chest pain and an abnormal EKG, and possible effects on the blood and kidney.
- The Reference Concentration (RfC) for mixed xylenes, *m*-, *o*-, and *p*-xylenes is under review by the U.S. Environmental Protection Agency (EPA).
- The Reference Dose (RfD) for mixed xylenes is 2 mg/kg/d.[a] The provisional RfD for *m*- and *o*-xylenes is also 2 mg/kg/d. EPA estimates that consumption of this dose or less, over a lifetime, would not likely result in the occurrence of chronic noncancer effects.[b]
- Insufficient data are available on the developmental or reproductive effects of mixed xylenes in humans. Animal studies have reported **developmental effects, such as an increased incidence of skeletal variations in fetuses, and fetal resorptions via inhalation.**
- No information is available on the carcinogenic effects of mixed xylenes in humans, and animal studies have reported negative results from exposure via gavage (experimentally placing the chemical in the stomach). EPA has classified mixed xylenes as a Group D, **not classifiable as to human carcinogenicity.**

---

[a] Milligrams per kilogram per day is one way to measure the amount of the contaminant that is consumed

in food.

[b] The RfD is not a direct estimator of risk but rather a reference point to gauge the potential effects. Exceedance of the RfD does not imply that an adverse health effect would necessarily occur. As the amount and frequency of exposures exceeding the RfD increase, the probability of adverse health effects also increases. The provisional RfD is a value that has had some form of Agency review, but it does not appear on the IRIS system.

Please Note: The main sources of information for this fact sheet are EPA's Integrated Risk Information System (IRIS), which contains information on oral chronic toxicity and the RfD, and the Agency for Toxic Substances and Disease Registry's (ATSDR's) *Toxicological Profile for Xylenes*. Other secondary sources include the Hazardous Substances Data Bank (HSDB), a database of summaries of peer-reviewed literature, and the Registry of Toxic Effects of Chemical Substances (RTECS), a database of toxic effects that are not peer reviewed.

Environmental/Occupational Exposure

- Mixed xylenes are distributed throughout the environment; they have been detected in air, rainwater, soils, surface water, sediments, drinking water, and aquatic organisms. (1)
- Ambient air concentrations of mixed xylenes in urban areas of the United States range from 0.003 to 0.38 mg/m^3. (1)
- Mixed xylenes have also been detected in indoor air; xylenes have been widely used in home use products such as paints. One study reported concentrations of *m*- and *p*-xylene ranging from 0.010 to 0.047 mg/m^3. (1)
- Levels of mixed xylenes in drinking water have been reported to range from 0.2 to 9.9 g/L, with mean concentrations of less than 2 g/L. (1)
- Occupational exposure to mixed xylenes may occur at workplaces where mixed xylenes are produced and used as industrial solvents. (1)
- Xylene exposure may be to any of the three isomers or to mixtures of the isomers. (1)

Assessing Personal Exposure

- Exposure to mixed xylenes may be determined by measuring the breakdown products of mixed xylenes in the urine. (1)

Health Hazard Information

Acute Effects:

- Human and animal data show that all xylene isomers or xylene mixtures produce similar effects, although specific isomers may not be equally potent in producing the effects. (1)
- Acute (short-term) inhalation exposure to mixed xylenes in humans has been associated with dyspnea and irritation of the nose and throat; gastrointestinal effects such as nausea, vomiting, and gastric discomfort; mild transient eye irritation; and neurological effects such as impaired short-term memory, impaired reaction time, performance decrements in numerical ability, and alterations in equilibrium and body balance. Acute dermal exposure in humans results in transient skin irritation

and dryness and scaling of the skin. (1-3)

- Acute inhalation exposure to a mixture of toluene and xylenes resulted in more than additive respiratory and neurological toxicity. (1)
- Acute animal studies have reported effects on the respiratory, cardiovascular, and central nervous systems and the kidney from inhalation exposure to mixed xylenes. (1)
- Acute animal tests, such as the LC_{50} and LD_{50} tests in rats and mice, have shown mixed xylenes to have low to moderate toxicity from inhalation exposure and moderate toxicity from oral exposure. (4,5)

Chronic Effects (Noncancer):

- Chronic (long-term) exposure of humans to mixed xylenes, as seen in occupational settings, has resulted primarily in neurological effects such as headache, dizziness, fatigue, tremors, and incoordination. Labored breathing, impaired pulmonary function, increased heart palpitation, severe chest pain, an abnormal EKG, and possible effects on the blood and kidney have also been reported. (1,2)
- Mixed xylenes have not been extensively tested for chronic effects, although animal studies show effects on the liver from inhalation exposure and effects on the blood, kidney, and CNS from oral exposure to mixed xylenes. (1)
- The RfC for mixed xylenes, *m*-, *o*-, and *p*-xylenes is under review by EPA. (6-9)
- The RfD for mixed xylenes is 2 mg/kg/d based on hyperactivity, decreased body weight, and increased mortality in rats, and the provisional RfD for *m*- and *o*-xylenes is also 2 mg/kg/d. EPA has not established an RfD or a provisional RfD for *p*-xylenes. (6,10)
- EPA has medium confidence in the study on which the RfD was based because it was a well-designed study in which adequately sized groups of two species were tested over a substantial portion of their lifespan, comprehensive histology was performed, and a no-observed-adverse-effect level (NOAEL) was defined; but clinical chemistries, blood enzymes, and urinalysis were not performed; medium confidence in the database because even though supporting data exist for mice, and teratogenicity and fetotoxicity data are available with positive results at high oral doses, a lowest-observed-adverse-effect level (LOAEL) for chronic oral exposure has not been defined; and, consequently, medium confidence in the RfD. (6)
- EPA's Office of Air Quality Planning and Standards, for a hazard ranking under Section 112(g) of the Clean Air Act Amendments, has evaluated mixed xylenes for chronic toxicity and has given them a composite score of 8 (scores range from 1 to 100, with 100 being the most toxic). These scores are nonlinear and are the product of two ratings: a rating based on the minimal-effect-dose and a rating based on the type of effect. (11)

Reproductive/Developmental Effects:

- Several human studies examined exposure to organic solvents (including mixed xylenes) and developmental effects. However, no conclusions can be drawn from these studies because they all involved concurrent exposure to multiple chemicals. (1)
- Mixed xylenes have been shown to produce developmental effects, such as an increased incidence of skeletal variations in fetuses, delayed ossification, fetal resorptions, hemorrhages in fetal organs, and decreased fetal body weight in animals via inhalation exposure. Some studies observed maternal

toxicity as well. (1-3)

Cancer Risk:

- No information is available on the carcinogenic effects of mixed xylenes in humans. (1)
- An increase in tumors was not reported in an animal study of exposure to mixed xylenes via gavage (experimentally placing the chemical in the stomach). Other animal studies have reported equivocal results. (1,3)
- EPA has classified mixed xylenes as a Group D, not classifiable as to human carcinogenicity. (6)

Physical Properties

- Mixed xylenes are colorless liquids with a sweet odor. (1)
- The odor threshold for *m*-xylene is 1.1 ppm. (4)
- The chemical formula for mixed xylenes is C_8H_{10}, and the molecular weight is 106.16 g/mol. (1)
- The vapor pressure for mixed xylenes is 6.72 mm Hg at 21 C, and the octanol/water partition coefficient (Log K_{ow}) is 3.12-3.20. (1)

Uses

- Mixed xylenes are used in the production of ethylbenzene, in solvents, and for paints and coatings and are blended into gasoline. (1)

Conversion Factors:

To convert from ppm to mg/m^3: mg/m^3 = (ppm) × (molecular weight of the compound)/(24.45). For xylenes: 1 ppm = 4.34 mg/m^3.

Health Data from Inhalation Exposure

Concentration (mg/m^3)	Health numbers[a]	Regulatory, advisory numbers[b]	Reference
1,000,000.0			
-- -- -- -- 100,000.0			
-- -- -- -- 10,000.0	• LC_{50} (mixed xylenes) (27,571 mg/m^3) • LC_{50} (*p*-xylene) (16,963 mg/m^3)		1,5 1,5

-- -- -- -- 1,000.0			
-- -- -- -- 100.0		• NIOSH REL (ceiling) (868 mg/m^3) • OSHA PEL and ACGIH TLV (STEL) (655 mg/m^3) • OSHA PEL, ACGIH TLV, and NIOSH REL (435 mg/m^3)	2 2 2

ACGIH STEL--American Conference of Governmental and Industrial Hygienists' short-term exposure limit; 15-min time-weighted-average exposure that should not be exceeded at any time during a workday even if the 8-h time-weighted-average is within the threshold limit value.
ACGIH TLV--American Conference of Governmental and Industrial Hygienists' threshold limit value expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effects.
LC_{50} (Lethal Concentration$_{50}$)--A calculated concentration of a chemical in air to which exposure for a specific length of time is expected to cause death in 50% of a defined experimental animal population.
NIOSH REL--National Institute of Occupational Safety and Health's recommended exposure limit; NIOSH-recommended exposure limit for an 8- or 10-h time-weighted-average exposure and/or ceiling.
OSHA PEL--Occupational Safety and Health Administration's permissible exposure limit expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effect averaged over a normal 8-h workday or a 40-h workweek.

[a] Health numbers are toxicological numbers from animal testing or risk assessment values developed by EPA.
[b] Regulatory numbers are values that have been incorporated in Government regulations, while advisory numbers are nonregulatory values provided by the Government or other groups as advice.

Xylenes; CASRN 1330-20-7

Health assessment information on a chemical substance is included in IRIS only after a comprehensive review of chronic toxicity data by U.S. EPA health scientists from several Program Offices and the Office of Research and Development. The summaries presented in Sections I and II represent a consensus reached in the review process. Background information and explanations of the methods used to derive the values given in IRIS are provided in the Background Documents.

STATUS OF DATA FOR Xylenes

File On-Line 09/30/1987

Category (section)	Status	Last Revised

Inhalation RfC Assessment (I.B.)	no data	

Carcinogenicity Assessment (II.) on-line 03/01/1991

_I. CHRONIC HEALTH HAZARD ASSESSMENTS FOR NONCARCINOGENIC EFFECTS

__I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

Substance Name -- Xylenes
CASRN -- 1330-20-7
Last Revised -- 09/30/1987

The oral Reference Dose (RfD) is based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. It is expressed in units of mg/kg-day. In general, the RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Please refer to the Background Document for an elaboration of these concepts. RfDs can also be derived for the noncarcinogenic health effects of substances that are also carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.A.1. ORAL RfD SUMMARY

Critical Effect	Experimental Doses*	UF	MF	RfD
Hyperactivity, decreased body weight and increased mortality (males) Chronic Rat Gavage Study NTP, 1986	NOAEL: 250 mg/kg/day (converted to 179 mg/kg/day) FEL: 500 mg/kg/day (converted to 357 mg/kg/day)	100	1	2E+0 mg/kg/day

---

*Conversion Factors: Dose adjusted for gavage schedule (5\days/week).

___I.A.2. PRINCIPAL AND SUPPORTING STUDIES (ORAL RfD)

NTP (National Toxicology Program). 1986. NTP Technical Report on the Toxicology and Carcinogenesis of Xylenes (mixed) (60.2% m-xylene, 13,6% p-xylene, 17.0 ethylbenzene and 9.1% 0-xylene) (CAS No. 1330-20-7) in F344/N rats and B6C3F1 mice (gavage studies). U.S. DHHS, PHS, NIH, NTP, Research Triangle Park, NC. NTP TR 327, NIH Publ. No. 86-2583.

Groups of 50 male and 50 female Fischer 344 rats and 50 male and 50 female B6C3F1 mice were given gavage doses of 0, 250, or 500 mg/kg/day (rats) and 0, 500, or 1000 mg/kg/day (mice) for 5 days/week for 103 weeks. The animals were observed for clinical signs of toxicity, body weight gain, and mortality. All animals that died or were killed at sacrifice were given gross necropsy and comprehensive histologic examinations. There was a dose-related increased mortality in male rats, and the increase was significantly greater in the high-dose group compared with controls. Although increased mortality was observed at 250 mg/kg/day, the increase was not significant. Although many of the early deaths were caused by gavage error, NTP (1986) did not rule out the possibility that the rats were resisting gavage dosing because of the behavioral effects of xylene. Mice given the high dose exhibited hyperactivity, a manifestation of CNS toxicity. There were no compound-related histopathologic lesions in any of the treated rats or mice. Therefore, the high dose is a FEL and the low dose a NOAEL.

___I.A.3. UNCERTAINTY AND MODIFYING FACTORS (ORAL RfD)

UF -- An uncertainty factor of 100 was chosen: 10 for species-to-species extrapolation and 10 to protect sensitive individuals.

MF -- None

___I.A.4. ADDITIONAL COMMENTS (ORAL RfD)

U.S. EPA (1984) reported an RfD of 0.01 mg/kg/day, based on a rat dietary NOAEL of 200 ppm or 10 mg/kg/day as defined by Bowers et al. (1982) in a 6-month study. This NOAEL was divided by an uncertainty factor of 1000. U.S. EPA (1985, 1986) noted that this study used aged rats, loss of xylene from volatilization was not controlled, only one exposure level was used, and histopathologic examination was incomplete. An RfD of 4.31 mg/day (about 0.06 mg/kg/day) based on an inhalation study (Jenkins et al., 1970) using rats,

guinea pigs, monkeys, and dogs exposed to o-xylene at 3358 mg/cu.m, 8 hours/day, 5 days/ week for 6 weeks or at 337 mg/cu.m continuously for 90 days was derived by U.S. EPA (1985). Deaths in rats and monkeys, and tremors in dogs occurred at the highest dose, whereas no effects were observed in the 337 mg/cu.m continuous exposure group. The RfD based on the NTP (1986) study is preferable because it is based on a chronic exposure in two species by a relevant route of administration, and comprehensive histology was performed. Xylene is fetotoxic and teratogenic in mice at high oral doses (Nawrot and Staples, 1981; Marks et al., 1982), but the RfD as calculated should be protective of these effects.

___I.A.5. CONFIDENCE IN THE ORAL RfD

Study -- Medium
Data Base -- Medium
RfD -- Medium

The NTP (1986) study was given a medium confidence level because it was a well-designed study in which adequately sized groups of two species were tested over a substantial portion of their lifespan, comprehensive histology was performed, and a NOAEL was defined; but clinical chemistries, blood enzymes, and urinalysis were not performed. The data base was given a medium confidence level because, although supporting data exist for mice and teratogenicity and fetotoxicity data are available with positive results at high oral doses, a LOAEL for chronic oral exposure has not been defined. Medium confidence in the RfD follows.

___I.A.6. EPA DOCUMENTATION AND REVIEW OF THE ORAL RfD

Source Document -- U.S. EPA, 1986, 1985, 1984

The Health and Environmental Effects Profile for Xylenes (o-, m-, p-) has received limited peer review and extensive agency-wide review, 1986.

The Drinking Water Criteria Document for Xylenes has received extensive peer and agency-wide review.

The Health Effects Assessment for Xylenes has received ECAO internal review and limited agency review.

Other EPA Documentation -- None

Agency Work Group Review -- 12/05/1985, 03/19/1987

Verification Date -- 03/19/1987

___I.A.7. EPA CONTACTS (ORAL RfD)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

__I.B. REFERENCE CONCENTRATION FOR CHRONIC INHALATION EXPOSURE (RfC)

Substance Name -- Xylenes
CASRN -- 1330-20-7

Not available at this time.

_II. CARCINOGENICITY ASSESSMENT FOR LIFETIME EXPOSURE

Substance Name -- Xylenes
CASRN -- 1330-20-7
Last Revised -- 03/01/1991

Section II provides information on three aspects of the carcinogenic assessment for the substance in question; the weight-of-evidence judgment of the likelihood that the substance is a human carcinogen, and quantitative estimates of risk from oral exposure and from inhalation exposure. The quantitative risk estimates are presented in three ways. The slope factor is the result of application of a low-dose extrapolation procedure and is presented as the risk per (mg/kg)/day. The unit risk is the quantitative estimate in terms of either risk per ug/L drinking water or risk per ug/cu.m air breathed. The third form in which risk is presented is a drinking water or air concentration providing cancer risks of 1 in 10,000, 1 in 100,000 or 1 in 1,000,000. The rationale and methods used to develop the carcinogenicity

information in IRIS are described in The Risk Assessment Guidelines of 1986 (EPA/600/8-87/045) and in the IRIS Background Document. IRIS summaries developed since the publication of EPA's more recent Proposed Guidelines for Carcinogen Risk Assessment also utilize those Guidelines where indicated (Federal Register 61(79):17960-18011, April 23, 1996). Users are referred to Section I of this IRIS file for information on long-term toxic effects other than carcinogenicity.

__II.A. EVIDENCE FOR CLASSIFICATION AS TO HUMAN CARCINOGENICITY

___II.A.1. WEIGHT-OF-EVIDENCE CLASSIFICATION

Classification -- D; not classifiable as to human carcinogenicity.

Basis -- Orally administered technical xylene mixtures did not result in significant increases in incidences in tumor responses in rats or mice of both sexes.

___II.A.2. HUMAN CARCINOGENICITY DATA

None.

___II.A.3. ANIMAL CARCINOGENICITY DATA

Inadequate. In an NTP (1986) study, 50 male and 50 female F344/N rats were treated by gavage with mixed xylenes in corn oil (60% m-xylene, 14% p-xylene, 9% o-xylene and 17% ethylbenzene) at dosages of 0, 250 or 500 mg/kg/day, 5 days/week for 103 weeks. Similarly, 50 male and 50 female B6C3F1 mice were treated with the same xylene mixture at dosages of 0, 500 or 1000 mg/kg/day. Animals were killed and examined histologically when moribund or after 104-105 weeks. An apparent dose-related increased mortality was observed in male rats, but this difference was statistically significant for the high dose group, only. No other differences in survival between dosage groups of either sex were observed. Interstitial cell tumors of the testes could not be attributed to administration of the test compound observed in male rats (43/50 control, 38/50 low-dose and 41/49 high-dose). NTP (1986) reported that there were no significant changes in the incidence of neoplastic or nonneoplastic lesions in either the rats or mice that could be considered related to the mixed xylene treatment, and concluded that under the conditions

of these 2-year gavage studies, there was "no evidence of carcinogenicity" of xylene (mixed) for rats or mice of either sex at any dosage tested.

Maltoni et al. (1985), in a limited study, reported higher incidences (compared with controls) of malignant tumors in male and female Sprague-Dawley rats treated by gavage with xylene in olive oil at 500 mg/kg/day, 4 or 5 days/week for 104 weeks. This study did not report survival rates or specific tumor types; therefore, the results cannot be interpreted.

Berenblum (1941) reported that "undiluted" xylene applied at weekly intervals produced one tumor-bearing animal out of 40 after 25 weeks in skin-painting experiments in mice. No control groups were described. Pound (1970) reported negative results in initiation-promotion experiments with xylene as the initiator and croton oil as the promotor.

___II.A.4. SUPPORTING DATA FOR CARCINOGENICITY

The frequency of sister chromatid exchanges and chromosomal aberrations were nearly identical between a group of 17 paint industry workers exposed to xylene and their respective referents (Haglund et al., 1980). In vitro, xylene caused no increase in the number of sister chromatid exchanges in human lymphocytes (Gerner-Smidt and Friedrich, 1978). Studies indicate that xylene isomers, technical grade xylene or mixed xylene are not mutagenic in tests with Salmonella typhimurium (Florin et al., 1980; NTP, 1986; Bos et al., 1981) nor in mutant reversion assays with Escherichia coli (McCarroll et al., 1981). Technical grade xylene, but not o- and m-xylene, was weakly mutagenic in Drosophila recessive lethal tests. Chromosomal aberrations were not increased in bone marrow cells of rats exposed to xylenes by inhalation (Donner et al., 1980).

__II.B. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM ORAL EXPOSURE

Not available.

__II.C. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM INHALATION

EXPOSURE

Not available.

__II.D. EPA DOCUMENTATION, REVIEW, AND CONTACTS (CARCINOGENICITY ASSESSMENT)

___II.D.1. EPA DOCUMENTATION

Source Document -- U.S. EPA, 1987

The Drinking Water Criteria Document for Xylene has received Agency and external review.

___II.D.2. REVIEW (CARCINOGENICITY ASSESSMENT)

Agency Work Group Review -- 12/02/1987

Verification Date -- 12/02/1987

___II.D.3. U.S. EPA CONTACTS (CARCINOGENICITY ASSESSMENT)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

Drinking Water and Health

As part of the Drinking Water and Health pages, this fact sheet is part of a larger publication:

National Primary Drinking Water Regulations

Consumer Factsheet on: XYLENES

This is a factsheet about a chemical that may be found in some public or private drinking water supplies. It may cause health problems if found in amounts greater than the health standard set by the United States Environmental Protection Agency (EPA).

What is Xylene and how is it used?

A xylene is any of a group of very similar organic compounds. They are clear liquids with a sweet odor. The greatest use of xylenes is as a solvent which is much safer than benzene. Other uses include: in gasoline as part of the BTX component (benzene-toluene-xylene); Xylene mixtures are used to make phthalate plasticizers, polyester fiber, film and fabricated items.

The list of trade names given below may help you find out whether you are using this chemical at home or work.

Trade Names and Synonyms:

Dimethyl benzene
Xylol
Methyltoluene
Violet 3

Why is Xylene being Regulated?

In 1974, Congress passed the Safe Drinking Water Act. This law requires EPA to determine safe levels of chemicals in drinking water which do or may cause health problems. These non-enforceable levels, based solely on possible health risks and exposure, are called Maximum Contaminant Level Goals.

The MCLG for xylenes has been set at 10 parts per million (ppm) because EPA believes this level of protection would not cause any of the potential health problems described below.

Based on this MCLG, EPA has set an enforceable standard called a Maximum Contaminant Level (MCL). MCLs are set as close to the MCLGs as possible, considering the ability of public water systems to detect and remove contaminants using suitable treatment technologies.

The MCL has been set at 10 ppm because EPA believes, given present technology and resources, this is the lowest level to which water systems can reasonably be required to remove

this contaminant should it occur in drinking water.

These drinking water standards and the regulations for ensuring these standards are met, are called National Primary Drinking Water Regulations. All public water supplies must abide by these regulations.

What are the Health Effects?

Short-term: EPA has found xylenes to potentially cause the following health effects when people are exposed to it at levels above the MCL for relatively short periods of time: disturbances of cognitive abilities, balance, and coordination.

Long-term: Xylenes has the potential to cause the following effects from a lifetime exposure at levels above the MCL: damage to the central nervous system, liver and kidneys.

How much Xylene is produced and released to the environment?

Production of xylenes was 6.84 billion lbs. in 1993. Major environmental releases of xylenes are due to evaporation from the refining and use of petroleum products. It may also be released by leaks or spills during the transport and storage of gasoline and other fuels. Xylenes are a natural products of many plants, and are a component of petroleum and coal tar.

From 1987 to 1993, according to EPA's Toxic Chemical Release Inventory, xylene releases to land and water totalled nearly 4.8 billion lbs. These releases were primarily from petroleum refining industries. The largest releases occurred in Texas. The largest direct releases to water occurred in New Jersey and Georgia.

What happens to Xylene when it is released to the environment?

Most of the xylenes are released into the atmosphere where they are quickly degraded by sunlight. When released to soil or water, xylenes will quickly evaporate. They may leach into ground water and persist there for several years. There is little potential for accumulation in aquatic life.

How will Xylene be Detected in and Removed from My Drinking Water?

The regulation for xylenes became effective in 1992. Between 1993 and 1995, EPA required your water supplier to collect water samples every 3 months for one year and analyze them to find out if xylenes is present above 0.5 ppb. If it is present above this level, the system must continue to monitor this contaminant.

If contaminant levels are found to be consistently above the MCL, your water supplier must take steps to reduce the amount of xylenes so that it is consistently below that level. The following treatment methods have been approved by EPA for removing xylenes: Granular activated charcoal in combination with Packed Tower Aeration.

How will I know if Xylene is in my drinking water?

If the levels of xylenes exceed the MCL, 10 ppm, the system must notify the public via newspapers, radio, TV and other means. Additional actions, such as providing alternative drinking water supplies, may be required to prevent serious risks to public health.

Drinking Water Standards:

Mclg: 10 ppm

Mcl: 10 ppm

Xylene Releases to Water and Land, 1987 to 1993 (in pounds):

		Water	Land
TOTALS (in pounds)		**875,943**	**3,897,738**
Top Ten States*

Major Industries*			
Petroleum refining		131,817	2,678,958
Metal barrels, drums		5	289,542
Textile finishing, misc.		278,454	0
Misc. Industrial chems.		95,706	69,696
Extruded Aluminum prod.		1,265	138,798
Furniture, fixtures		0	91,500
Cotton fabric finishing		68,310	15,000
Wood office furniture		0	67,677
Pharmaceuticals		52,285	3,100
Paper mills		52,480	2,122

* Water/Land totals only include facilities with releases greater than a certain amount - usually 1000 to 10,000 lbs.

Learn more about your drinking water!

EPA strongly encourages people to learn more about their drinking water, and to support local efforts to protect and upgrade the supply of safe drinking water. Your water bill or telephone books government listings are a good starting point.

Your local water supplier can give you a list of the chemicals they test for in your water, as well as how your water is treated.

Your state Department of Health/Environment is also a valuable source of information.

For help in locating these agencies or for information on drinking water in general, call: EPAs Safe Drinking Water Hotline: (800) 426-4791.

For additional information on the uses and releases of chemicals in your state, contact the: Community Right-to-Know Hotline: (800) 535-0202.

NTP CHEMICAL REPOSITORY (RADIAN CORPORATION, AUGUST 29, 1991)
XYLENES (MIXED)

-IDENTIFIERS
 ===========

*CATALOG ID NUMBER: 001205

*CAS NUMBER: 1330-20-7

*BASE CHEMICAL NAME: XYLENES,MIXED

*PRIMARY NAME: XYLENES (MIXED)

*CHEMICAL FORMULA: C8H10

*STRUCTURAL FORMULA: C6H4(CH3)2

*WLN: 1R X

*SYNONYMS:
  COMPONENT 1 (83%): XYLENES
                     DIMETHYLBENZENES
                     XYLOL
  COMPONENT 2 (17%): ETHYL BENZENE

-PHYSICAL CHEMICAL DATA
 ======================

*PHYSICAL DESCRIPTIONS: LITERATURE: Colorless liquid
                        REPOSITORY: Colorless liquid

*MOLECULAR WEIGHT: 106.17

*SPECIFIC GRAVITY: 0.860 @ 20/4 C [269,274]

*DENSITY: Not available

*MP (DEG C): Not available

*BP (DEG C): 137-144 C [053,269,274]

*SOLUBILITIES:
       WATER : <1 mg/mL @ 22 C (RAD)

        DMSO : >=100 mg/mL @ 22 C (RAD)

 95% ETHANOL : >=100 mg/mL @ 22 C (RAD)

    METHANOL : Not available

     ACETONE : >=100 mg/mL @ 22 C (RAD)

     TOLUENE : Not available

*OTHER SOLVENTS:
  Absolute alcohol: Miscible [031]
  Ether: Soluble [062]
  Organic solvents: Miscible [421]

*VOLATILITY:
Vapor pressure: 6.72 mm Hg @ 21 C [042]; 10 mm Hg @ 28 C [053]
Vapor density : 3.7

*FLAMMABILITY(FLASH POINT):
This chemical has a flash point of 25.6 C (78 F) (RAD). It is flammable. Fires involving this material can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. The autoignition temperature for this compound is 466 C (870 F) [058].

*UEL: 7.0% [036,053] LEL: 1.0 % [036,053]

*REACTIVITY:
This compound reacts with oxidizing agents [042,053,269]. It will attack some forms of plastics, rubber and coatings. It readily dissolves fats, oils and waxes [430].

*STABILITY:
This compound is stable under normal laboratory conditions. Solutions of this chemical in water, DMSO, 95% ethanol or acetone should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Refractive index: 1.4970 @ 20 C
Aromatic odor

-TOXICITY
========

*NIOSH REGISTRY NUMBER: ZE2100000

*TOXICITY:

typ. dose	mode	specie	amount	unit	other
TCLo	ihl	hmn	200	ppm	
LCLo	ihl	man	10000	ppm/6H

  Reproductive Effects Data:
   TCLo: ihl-rat   1000 mg/m3/24H (9-14D preg)
   TCLo: ihl-rat     50 mg/m3/6H (1-21D preg)
   TCLo: ihl-rat    600 mg/m3/24H (7-15D preg)
   TDLo: orl-mus  20600 ug/kg (6-15D preg)
   TCLo: ihl-mus   4000 ppm/6H (6-12D preg)
   TDLo: orl-mus     31 mg/kg (6-15D preg)
   TCLo: ihl-mus   2000 ppm/6H (6-12D preg)

*STANDARDS, REGULATIONS & RECOMMENDATIONS:
  OSHA: Federal Register (1/19/89) and 29 CFR 1910.1000 Subpart Z
        Transitional Limit: PEL-TWA 100 ppm [610]
        Final Limit: PEL-TWA 100 ppm; STEL 150 ppm [610]
  ACGIH: TLV-TWA 100 ppm; STEL 150 ppm [610]
  NIOSH Criteria Document: Recommended Exposure Limit to this compound-air:
                           TWA 100 ppm; Ceiling Limit 200 ppm/10M [015,610]
  NFPA Hazard Rating: Health (H): 2
                      Flammability (F): 3
                      Reactivity (R): 0
  H2: Materials hazardous to health, but areas may be entered freely with
      full-faced mask self-contained breathing apparatus which provides
      eye protection (see NFPA for details).
  F3: Materials which can be ignited under almost all normal temperature
      conditions (see NFPA for details).
  R0: Materials which are normally stable even under fire exposure conditions
      and which are not reactive with water (see NFPA for details).

*OTHER TOXICITY DATA:
  Skin and Eye Irritation Data:
    eye-hmn  200  ppm
    skn-rbt  100% MOD
    skn-rbt  500  mg/24H MOD
    eye-rbt   87  mg MLD
    eye-rbt    5  mg/24H SEV
  Standards and Regulations: DOT-Hazard: Flammable liquid; Label: Flammable
                              liquid
                             DOT-IMO: Flammable or Combustible liquid; Label:
                              Flammable liquid
  Status: NIOSH Analytical Methods: see hydrocarbons, aromatic, 1501
          EPA TSCA Chemical Inventory, 1986
          EPA TSCA 8(a) Preliminary Assessment Information, Final Rule
          EPA Genetox Program 1986, Negative: In vitro SCE-human lymphocytes;
           In vitro SCE-human

-OTHER DATA (Regulatory)
 ======================

*PROPER SHIPPING NAME (IATA): Xylenes

*UN/ID NUMBER: UN1307

*HAZARD CLASS: 3             SUBSIDIARY RISK: None    PACKING GROUP: III

*LABELS REQUIRED: Flammable liquid
```

*PACKAGING: PASSENGER: PKG. INSTR.: 309, Y309 MAXIMUM QUANTITY: 60 L, 10 L
CARGO : PKG. INSTR.: 310 MAXIMUM QUANTITY: 220 L

*SPECIAL PROVISIONS: None

*USES:
Aviation gasoline; protective coatings; solvent for alkyd resins, lacquers, enamels, rubber cements; synthesis of organic chemicals; manufacturing dyes, sterilizing catgut; with Canada balsam as oil-immersion in microscopy and cleaning agent in microscopic technique.

*COMMENTS: Not available

-HANDLING PROCEDURES

*ACUTE/CHRONIC HAZARDS:
When heated to decomposition, this compound emits toxic fumes of CO and CO2 [269]. It can be narcotic in high concentrations [031,051,053,269]. It causes eye, nose and throat irritation [346].

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS:
Recommended Glove Type For Use With Neat (Undiluted) Chemical:
Recommendations based on permeation test results are made for handling the neat (undiluted) chemical. If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.

Suggested Glove Type (RAD)	Model Number	Thickness	Breakthrough Time
PVA	Edmont 29-250	0.84 mm	480 min.
Viton	North F-091	0.41 mm	480 min.

*RECOMMENDED RESPIRATOR:
Where the neat test chemical is weighed and diluted, wear a NIOSH-approved half face respirator equipped with an organic vapor/acid gas cartridge (specific for organic vapors, HCl, acid gas and SO2) with a dust/mist filter.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should store this chemical in an explosion-proof refrigerator and keep it away from oxidizing materials. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you spill this chemical, FIRST REMOVE ALL SOURCES OF IGNITION. Then, use absorbent paper to pick up all liquid spill material. Your contaminated clothing and absorbent paper should be sealed in a vapor-tight plastic bag for eventual disposal. Solvent wash all contaminated surfaces with 60-70% ethanol followed by washing with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT: Not available

-EMERGENCY PROCEDURES

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a hospital or poison control center. Be prepared to transport the victim to a hospital if advised by a physician.
If the victim is convulsing or unconscious, do not give anything by mouth, ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport the victim to a hospital.

*SYMPTOMS:
Symptoms of exposure to this material include irritation of the eyes, nose and throat; drying and defatting of the skin which may lead to dermatitis; chemical pneumonitis, pulmonary edema, hemorrhage, central nervous system depression, dizziness, staggering, drowsiness, unconsciousness, anorexia, nausea, vomiting and abdominal pain [346]. It may be narcotic in high concentrations [031,051,053,269]. It may also cause headache, fatigue, lassitude, irritability and gastrointestinal disturbances [421]. It can also cause reversible eye damage, a burning sensation in the mucous membranes, salivation, bloody vomit, impaired motor coordination, slurred speech, ataxia, stupor, coma, tremors, shallow respiration, ventricular irregularities, paralysis and convulsions [301]. It causes eye irritation and foggy vision [099].

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

ISOPROPYL ALCOHOL (67-63-0)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards**

  Recognized: --

  Suspected:

	Reference(s)
Cardiovascular or Blood Toxicant	RTECS
Developmental Toxicant	OEHHA-2000
Gastrointestinal or Liver Toxicant	RTECS
Kidney Toxicant	OEHHA-2000
Neurotoxicant	RTECS
Respiratory Toxicant	OEHHA-AREL RTECS
Skin or Sense Organ Toxicant	OEHHA-AREL

- **Hazard Rankings**

  More hazardous than most chemicals in 1 out of 8 ranking systems.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.
  Used in at least 14 industries.
  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.
  Used in pesticide products.

- **Profile of Environmental Release and Waste Generation**

  No data on environmental releases in Scorecard.

- **Regulatory Coverage**

  On at least 3 federal regulatory lists.

- **Basic Testing to Identify Chemical Hazards**

  Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

- **Information Needed for Safety Assessment**

  Lacks at least some of the national data required for safety assessment.
  Scorecard has risk assessment data for this chemical.

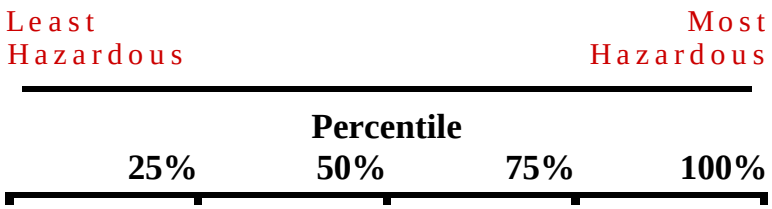
- **Links**

  Other web sites specific to this chemical:

  - CalEPA Air Resources Board Toxic Air Contaminant Summary

- IPCS International Chemical Safety Card
- National Toxicology Program Health and Safety Information Sheet
- New Jersey Fact Sheet

If none of these sources meet your needs, you can try searching some other chemical database Web sites.



- **Notes**

  This is not a TRI chemical even though TRI uses this CAS. See the chemical profile for ISOPROPYL ALCOHOL (STRONG ACID PROCESS) for information on the form of isopropyl alcohol on the TRI list.

Consumer Products

that contain ISOPROPYL ALCOHOL (67-63-0) from Scorecard

What kinds of consumer products may contain this chemical?

- Acid nonhousehold metal cleaners (liquid)
- Aerosol paint concentrates
- Aftershave preparations (all forms)
- Agricultural chemicals
- Antiacne preparations
- Antifreeze preparations
- Antifungal preparations
- Architectural coatings
- Auto, other transportation, and machinery refinish paints incl primers
- Automobile body polish and cleaners
- Automotive windshield washer fluid
- Bathroom tub and tile cleaners
- Body lotions
- Chemical products for pools, hot tubs, etc.
- Cleansing creams
- Cleansing lotions
- Deodorants/air fresheners (non-personal, aerosol)
- Deodorants/air fresheners (non-personal, non-aerosol)
- Disinfectants (nonagricultural)
- Emollients and protectives, including burn remedies and ointment bases
- Epoxy adhesives
- External analgesics and counterirritants
- External analgesics and counterirritants (liquid)
- External analgesics and counterirritants (ointments, pastes, creams, etc.
- Eye and ear pharmaceutical preparations
- Fabric softeners (liquid)
- Facial scrubs and masks
- Flexographic inks
- Floor polish
- Floor polish: liquid non-emulsion
- Fungicides for agric., garden and health service use
- Furniture polish and cleaners

- General antibacterials and antieptics
- General performance sealants (PVAC, butyl, vinyl, etc.)
- Glass window cleaning preparations
- Ground/traffic marking coatings
- Hair coloring preparations (bleaches, dyes, rinses, tints, etc.)
- Hair dressings incl brilliantines, creams, pomades
- Hair preparations (including shampoos)
- Hair tonics incl hair and scalp conditioners (consumer use)
- Hairspray (aerosol)
- Hairspray (non-aerosol)
- Herbicides for agric., garden and health service use
- Household alkaline machine dishwashing detergents (liquid)
- Household dry automatic dishwashing detergents
- Household hard surface cleaners (aerosol)
- Household hard surface cleaners (dry)
- Household hard surface cleaners (liquid)
- Household laundry presoaks
- Household liquid laundry detergents
- Household pesticides
- Household rug and upholstery cleaners
- Industrial particleboard (furniture, fixtures, cabinets, etc.)
- Insect repellants for human use
- Insecticides for agric., garden and health service use
- Insecticides for crawling insects
- Insecticides for flying insects
- Laundry starch preparations
- Leather dressings and finishes (excl shoe polish)
- Lubricating oils
- Miscellaneous agricultural/pesticidal products
- Miscellaneous paint-related products
- Moisturizing creams
- Nail enamel and polish removers
- Nail enamels and polishes
- Nonhousehold machine dishwashing detergents (liquid)
- Nonhousehold synthetic detergents (liquid, cationic or amphoteric base)
- Nonstructural caulking compounds and sealants
- Other alkaline household detergents

- Other alkaline nonhousehold detergents (liquid)
- Other alkaline nonhousehold dry detergents
- Other art materials incl clay, water & tempera colors, finger paint, etc.
- Other automotive chemicals
- Other cosmetics and toiletries
- Other dermatological preparations
- Other flexographic inks
- Other gravure inks
- Other hair preparations, including heat setting wave solutions
- Other indust. product finishes excl. pigment dispersions & ink vehicles
- Other industrial chemical specialty products
- Other laundry aids, icluding ironing aids and dry cleaning spotting pre
- Other lotions and oils, excl hair, shaving, and bath
- Other manicuring preparations
- Other miscellaneous allied paint products, including brush cleaners
- Other pharmaceutical preparations acting on the skin
- Other polishing preparations and related products
- Other soaps incl mechanics and medicated (bars, liquid and paste)
- Other specialty cleaning and sanitation products
- Oven cleaners
- Packaging inks: solvent types
- Packaging inks: water types
- Paint and varnish removers
- Paint thinners
- Paints and allied products
- Perfumes, toilet water, and colognes
- Pet flea and tick products, including collars
- Pharmaceutical preparations
- Pharmaceuticals for veterinary use
- Premoistened towelettes, incl wipes for babies
- Repellants and attractants
- Rubbing alcohol
- Rug and upholstery cleaners
- Shampoos
- Shoe polishes and cleaners
- Specialty performance sealants
- Suntan lotions and oils

- Synthetic resin and rubber adhesives
- Textile finishes
- Toilet bowl cleaners
- Toilet preparations
- Toilet soap excl medicated soaps (liquid)
- Topical antibiotic preparations
- Wood office furniture

Basic Testing to Identify Chemical Hazards

for ISOPROPYL ALCOHOL (67-63-0) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

More on the importance of basic toxicity testing

Safety Assessment Data

for ISOPROPYL ALCOHOL (67-63-0) from Scorecard

Are Risk Assessment Values Available?

Health Risk of Concern	Inhalation	Ingestion
Cancer	Not a recognized carcinogen	Not a recognized carcinogen
Noncancer	**No**	**No**

Are Exposure Data Available?

Type of Exposure	
Inhalation - ambient air	**No**
Inhalation - indoor air	**No**
Ingestion	**No**

- See the data US EPA possesses for safety assessment.

Scorecard Risk Characterization Data

for ISOPROPYL ALCOHOL (67-63-0) from Scorecard

Risk Assessment Values or Standards

	Value	Units	Reference
Inhalation cancer risk value (potency)	Not a recognized or suspect carcinogen		
Inhalation noncancer risk value (reference concentration)	7000	ug/m3	OEHHA2000-REL
National ambient air quality standard	Gap in regulatory coverage		
Ingestion cancer risk value (potency)	Not a recognized or suspect carcinogen		
Ingestion noncancer risk value (reference dose)	Data gap		
National water quality standard	Gap in regulatory coverage		

See the data US EPA possesses for safety assessment.

ISOPROPYL ALCOHOL

CAS Registry Number: 67-63-0

Structure: $CH_3CHOHCH_3$

Molecular Formula: C_3H_8O

Description

Isopropyl alcohol is a volatile, flammable, clear, colorless liquid which has a slight odor resembling that of a mixture of ethanol and acetone. It has a bitter taste. Although miscible with water, other alcohols, ether, and chloroform, it is insoluble in salt solutions (Merck, 1989).

Physical Properties of Isopropyl alcohol

Molecular Weight	60.09
Boiling Point	82.5 oC
Melting Point	-88.5 oC
Flash Point	11.7 oC (53 oF) (closed cup)
Vapor Pressure	44 mm Hg at 25 oC
Density/Specific Gravity	0.7851 at 20/4 oC (water = 1)
Log/Octanol Water Partition Coefficient	0.05
Dissociation Constants	pka: 17.1 at 25 oC
Autoignition Temp	455.6 oC (852 oF)
Henry's Law Constant	8.07 x 10-6 atm-m3/mole
Vapor Density	2.08 (air = 1)
Conversion Factor	1 ppm = 2.45 mg/m3

(HSDB, 1991)

SOURCES AND EMISSIONS

A. Sources

Isopropyl alcohol is used in the manufacture of acetone, glycerol, isopropyl acetate, shellacs, quick drying inks, and creosote. It is a solvent for essential and other oils, alkaloids, gums, resins, coatings and cellulose, and a deicing agent for liquid fuels, lacquers, and extraction processes. It is also used in antifreeze compositions and as an antiseptic (Sax, 1987; Howard, 1990; Merck, 1989).

Isopropyl alcohol is registered as an antimicrobial, bactericide, fungicide, and virucide. It is used for

sterilizing and disinfecting surfaces in hospitals, dairy farms, food processing plants, eating establishments, and in household dwellings. Isopropyl alcohol is also registered for use as a topical disinfectant in animal areas in and around the house, in veterinary institutions, farm structures, poultry areas, and in hatcheries and zoo animal premises. It is registered for use in barbershops for cleaning hair cutting and styling instruments and equipment. Isopropyl alcohol is also registered as an adjuvant, used to facilitate pesticide applications in agricultural settings, and as an adjuvant in industrial water washer, cooler, and condenser systems (DPR, 1996).

The licensing and regulation of pesticides for sale and use in California are the responsibility of the Department of Pesticide Regulation (DPR). Information presented in this fact sheet regarding the permitted pesticidal uses of isopropyl alcohol has been collected from pesticide labels registered for use in California and from DPR's pesticide databases. This information reflects pesticide use and permitted uses in California as of October 15, 1996. For further information regarding the pesticidal uses of this compound, please contact the Pesticide Registration Branch of DPR (DPR, 1996).

The primary stationary sources that have reported emissions of isopropyl alcohol in California are the leather tanning and finishing industry, manufacture of miscellaneous food and kindred products, and commercial printing facilities (ARB, 1997b).

B. Emissions

Emissions can be generated from petroleum storage, auto exhaust, plastics combustion, printing, sewage treatment, wood pulping, as well as consumer products (Howard, 1990). The total emissions of isopropyl alcohol from stationary sources in California are estimated to be at least 310,000 pounds per year, based on data reported under the Air Toxics "Hot Spots" Program (AB 2588) (ARB, 1997b).

C. Natural Occurrence

Isopropyl alcohol occurs as a plant volatile and has been found in animal waste and microbes (Howard, 1990).

AMBIENT CONCENTRATIONS

No Air Resources Board data exist for ambient measurements of isopropyl alcohol.

INDOOR SOURCES AND CONCENTRATIONS

Isopropyl alcohol is a component of many antiseptic and cosmetic products used indoors. No information about indoor concentrations of isopropyl alcohol was found in the readily-available literature.

ATMOSPHERIC PERSISTENCE

Isopropyl alcohol exists in the atmosphere in the gas phase. The dominant atmospheric loss process for isopropyl alcohol in the troposphere is by reaction with the hydroxyl radical. Based on this reaction, the

atmospheric half-life and lifetime of isopropyl alcohol is estimated to be 1.9 days and 2.7 days, respectively (Atkinson, 1994). The major reaction product from this reaction is acetone (Atkinson, 1995).

AB 2588 RISK ASSESSMENT INFORMATION

Although isopropyl alcohol is reported as being emitted in California from stationary sources no health values (cancer or non-cancer) are listed in the California Air Pollution Control Officers Association Air Toxics "Hot Spots" Program Revised 1992 Risk Assessment Guidelines for use in risk assessments (CAPCOA, 1993).

HEALTH EFFECTS

Probable routes of human exposure to isopropyl alcohol are inhalation and ingestion.

Non-Cancer: Isopropyl alcohol vapors are mildly irritating to the eyes and upper respiratory tract. At high levels, isopropyl alcohol can cause central nervous system (CNS) depression. Symptoms of poisoning include dizziness, incoordination, headache, and confusion. Isopropyl alcohol is metabolized to acetone which may prolong or potentiate the CNS depression. Isopropyl alcohol may enhance the hepatotoxicity of carbon tetrachloride (Olson, 1994).

The United States Environmental Protection Agency (U.S. EPA) has not established a Reference Concentration (RfC) or an oral Reference Dose (RfD) for isopropyl alcohol (U.S. EPA, 1995a).

Limited information is available on the reproductive toxicity of isopropyl alcohol. In the rat, high maternally-toxic inhalation exposures were associated with reduced fetal weight and increased skeletal and visceral malformations (HSDB, 1995).

Cancer: The U.S. EPA has not classified isopropyl alcohol as to its carcinogenic potential (U.S. EPA, 1995a). The International Agency for Research on Cancer has classified isopropyl alcohol in Group 3: Not classifiable as to its carcinogenic potential (IARC, 1987a).

International Chemical Safety Cards

ISOPROPYL ALCOHOL

ICSC: 0554

ISOPROPYL ALCOHOL
2-propanol
Isopropanol
$C_3H_8O/(CH_3)_2CHOH$
Molecular mass: 60.1

CAS # 67-63-0
RTECS # NT8050000
ICSC # 0554
UN # 1219
EC # 603-003-00-0

TYPES OF HAZARD/ EXPOSURE	ACUTE HAZARDS/ SYMPTOMS	PREVENTION	FIRST AID/ FIRE FIGHTING
FIRE	Highly flammable. Heating will cause rise in pressure with risk of bursting.	NO open flames, NO sparks, and NO smoking.	Powder, alcohol-resistant foam, water in large amounts, carbon dioxide.
EXPLOSION	Vapour/air mixtures are explosive.	Closed system, ventilation, explosion-proof electrical equipment and lighting.	In case of fire: keep drums, etc., cool by spraying with water.
EXPOSURE			
• **INHALATION**	Cough. Dizziness. Drowsiness. Headache. Nausea. Sore throat. Vomiting.	Ventilation, local exhaust, or breathing protection.	Fresh air, rest. Refer for medical attention.
• **SKIN**	Redness.	Protective gloves.	Remove contaminated clothes. Rinse skin with water.
• **EYES**	Redness. Pain. Blurred vision.	Safety goggles.	First rinse with plenty of water for several minutes (remove contact lenses if easily possible), then take to a doctor.
• **INGESTION**	Dizziness. Drowsiness. Nausea. Sore throat. Vomiting.	Do not eat, drink, or smoke during work.	Do NOT induce vomiting. Refer for medical attention.

SPILLAGE DISPOSAL	STORAGE	PACKAGING & LABELLING

Evacuate danger area! Collect leaking liquid in sealable containers. Absorb remaining liquid in sand or inert absorbent and remove to safe place.	Fireproof. Separated from strong oxidants. Cool. Keep in a well-ventilated room.	F symbol R: 11 S: 7-16 Note: C UN Hazard Class: 3 UN Packing Group: II

International Chemical Safety Cards

ISOPROPYL ALCOHOL

ICSC: 0554

IMPORTANT DATA

PHYSICAL STATE; APPEARANCE:
CLEAR COLOURLESS LIQUID.

PHYSICAL DANGERS:
The vapour mixes well with air, explosive mixtures are easily formed.

CHEMICAL DANGERS:
Reacts with strong oxidants.

OCCUPATIONAL EXPOSURE LIMITS (OELs):
TLV: 400 ppm; 983 mg/m^3 (as TWA); 500 ppm; 1230 mg/m^3 (as STEL) (ACGIH 1991-1992).
OSHA PEL: TWA 400 ppm (980 mg/m^3)
NIOSH REL: TWA 400 ppm (980 mg/m^3) ST 500 ppm (1225 mg/m^3)
NIOSH IDLH: 2000 ppm LEL

ROUTES OF EXPOSURE:
The substance can be absorbed into the body by inhalation of its vapour, by inhalation of its aerosol and by ingestion.

INHALATION RISK:
A harmful contamination of the air can be reached rather quickly on evaporation of this substance at 20°C.

EFFECTS OF SHORT-TERM EXPOSURE:
The substance irritates the eyes, the skin and the respiratory tract. The substance may cause effects on the central nervous system , resulting in depression. Exposure far above the OEL may result in unconsciousness. The effects may be delayed. Medical observation is indicated.

EFFECTS OF LONG-TERM OR REPEATED EXPOSURE:
Repeated or prolonged contact with skin may cause dermatitis.

PHYSICAL PROPERTIES

Boiling point: 83°C
Melting point: -90°C
Relative density (water = 1): 0.79
Solubility in water: Miscible
Vapour pressure, kPa at 20°C: 4.4
Relative vapour density (air = 1): 2.1
Relative density of the vapour/air-mixture at 20°C (air = 1): 1.05
Flash point: 11.7°C
Auto-ignition temperature: 455°C
Explosive limits, vol% in air: 2-12
Octanol/water partition coefficient as log Pow: <0.28

ENVIRONMENTAL DATA

It is strongly advised not to let the chemical enter into the environment.

NOTES
Use of alcoholic beverages enhances the harmful effect. Transport Emergency Card: TEC (R)-544 NFPA Code: H 1; F 3; R 0;

 ======================

*PHYSICAL DESCRIPTION: LITERATURE: Clear colorless liquid
                       REPOSITORY: Clear colorless liquid

*MOLECULAR WEIGHT: 60.10

*SPECIFIC GRAVITY: 0.785 @ 20/4 C [055,371]

*DENSITY: Not available

*MP (DEG C): -88.5 C [029,031,051,371]

*BP (DEG C): 82.5 C [031,043,301,346]

*SOLUBILITIES:
WATER : >=100 mg/mL @ 22 C (RAD)

DMSO : >=100 mg/mL @ 22 C (RAD)

95% ETHANOL : >=100 mg/mL @ 22 C (RAD)

METHANOL : Not available

ACETONE : >=100 mg/mL @ 22 C (RAD)

TOLUENE : Not available

OTHER SOLVENTS:
Alcohol: Miscible [016,031,043,295]
Benzene: Soluble [016]
Chloroform: Miscible [031,043,295,430]
Ether: Miscible [031,043,062,295]
Salt solutions: Insoluble [031,043,051]
Glycerol: Miscible [295]

*VOLATILITY:
Vapor pressure: 33 mm Hg @ 20 C [051,058,062,421]; 40 mm Hg @ 23.8 C [301]
Vapor density : 2.07 [043,051,055]

*FLAMMABILITY(FLASH POINT):
This chemical has a flash point of 12 C (53 F) [031,036,043,451]. It is flammable. Fires involving this material can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. The autoignition temperature is 399 C (750 F) [036,371,451].

*UEL: 12% [043,051,058,421] LEL: 2.0% [051,058,421,451]

*REACTIVITY:
This chemical reacts with air or oxygen to form dangerously unstable peroxides. Contact with 2-butanone increases the reaction rate for peroxide formation. A violent, explosive reaction occurs when it is heated with (aluminum isopropoxide + crotonaldehyde). It forms explosive mixtures with trinitromethane and hydrogen peroxide. This chemical reacts with barium perchlorate to form a highly explosive compound. It ignites on contact with dioxygenyl tetrafluoroborate, chromium trioxide and potassium-tert-butoxide. Vigorous reactions occur with (hydrogen + palladium), nitroform, oleum, $COCl_2$, aluminum triisopropoxide and oxidizers [043]. It also reacts explosively with phosgene in the presence of iron salts [451]. It is incompatible with acids, acid anhydrides, halogens and aluminum [269].

*STABILITY:
This chemical is sensitive to heat [043]. Solutions of this chemical in water, DMSO, 95% ethanol or acetone should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Specific gravity: 0.78084 @ 25/4 C; 0.728 @ 83/4 C [031]
Specific gravity: 0.7874 @ 20/20 C [430]
Freezing point: -89.5 C [029,031,047,275]
Vapor pressure: 44 mm Hg @ 25 C [430]

Bitter taste [031,043,295]
Odor recognition threshold limit: 7.5 ppm [058]
Evaporation rate (n-butyl acetate = 1): 1.4 [058]
Boiling point: 67.8 C @ 400 mm Hg; 53.0 C @ 200 mm Hg [031]
Boiling point: 39.5 C @ 100 mm Hg; 30.5 C @ 60 mm Hg; 23.8 C @ 40 mm Hg [031]
Boiling point: 12.7 C @ 20 mm Hg; 2.4 C @ 10 mm Hg; -7.0 C @ 5 mm Hg [031]
Forms an azeotrope with water (boiling point: 80.37 C @ 760 mm Hg; density: 0.83361 @ 0/4 C) [031]
Specific heat: 0.65 cal/g [062]
Critical temperature: 235 C [051,371]
Critical pressure: 53 atmospheres [062]
Heat of combustion: 14346 Btu/lb [062]
Heat of vaporization: 288 Btu/lb [062]
Viscosity: 2.1 centipoise @ 25 C [062]
log P octanol: -0.16/0.28 (calculated) [055]
Slight odor [043,051]
Refractive index: 1.3852 @ 8 C; 1.3802 @ 15 C; 1.3749 @ 25 C [031]
Refractive index: 1.3776 @ 20 C [016,029,047]
Burning rate: 2.3 mm/min [371]

*PROPER SHIPPING NAME (IATA): Isopropanol

*UN/ID NUMBER: UN1219

*HAZARD CLASS: 3 SUBSIDIARY RISK: None PACKING GROUP: II

*LABELS REQUIRED: Flammable liquid

*PACKAGING: PASSENGER: PKG. INSTR.: 305, Y305 MAXIMUM QUANTITY: 5 L, 1 L

CARGO : PKG. INSTR.: 307 MAXIMUM QUANTITY: 60 L

*SPECIAL PROVISIONS: None

*USES:
This compound is used as a solvent in perfumery and cosmetics, in the preservation of pathological specimens and dehydration of tissues, as a non-aqueous moistening agent for tablet granulation, in hair preparations, in lotions, in liniments, as a solvent for creosote, resins, gums, inks, oils, lotions, shellac and essential oils, as an antifreeze mixture and as an extraction solvent in food preparation. It is externally substituted for industrial methylated spirit and surgical spirit. It is also used in the extraction of alkaloids, in quick-drying oils, in quick-drying inks, in the denaturing of ethyl alcohol, in body rubs, in after-shave lotions, in the manufacture of acetone, glycerol and isopropyl acetate; as a pharmaceutic aid (solvent), as an antiseptic, as a rubefacient, as a deicing agent for liquid fuels, as a dehydrating agent, as a window cleaner, in permanent hair wave preparations, in dye solutions, as a disinfectant and in pliable ice packs.

*COMMENTS: Not available

-HANDLING PROCEDURES

*ACUTE/CHRONIC HAZARDS:
This compound is an irritant of the skin, eyes, mucous membranes and upper respiratory tract [269]. It is flammable and flashback along the vapor trail may occur [371]. When heated to decomposition it emits acrid smoke and toxic fumes of carbon monoxide, carbon dioxide and unidentified organic compounds [043,058,269].

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS:
GlovES+ Expert System Glove Types For The Neat (Undiluted) Chemical:
This chemical has not been tested for permeation by Radian Corporation; however, the GlovES+ expert system was used to extrapolate permeation test information from compounds in the same chemical class. The GlovES+ system uses permeation data from literature sources; therefore, extra safety margins should be used with the estimated protection time(s). If this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, replace them at once.
The GlovES+ expert system is a tool that can help people better manage protection from chemicals, however this tool cannot replace sound judgment nor make technical decisions. Our GlovES+ expert system is designed to offer initial advice and assistance in glove selection while the final glove selection should be made by knowledgeable individuals based on the specific circumstances involved.

Glove Type	Model Number	Thickness	Estimated Protection Time
Neoprene	Ansell Neoprene 530	0.46 mm	360 min
Nitrile	Pioneer A-14	0.56 mm	480 min
PE/EVAL/PE	Safety4 4H	0.07 mm	240 min
PVC	Comasec Multitop	0.07 mm	480 min

*RECOMMENDED RESPIRATOR:
When working with this chemical, wear a NIOSH-approved full face chemical cartride respirator equipped with the appropriate organic vapor cartridges. If that is not available, a half face respirator similarly

equipped plus airtight goggles can be substituted. However, please note that half face respirators provide a substantially lower level of protection than do full face respirators.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should store this material in a refrigerator. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you should spill this chemical, use absorbent paper to pick up all liquid spill material. Seal the absorbent paper, as well as any of your clothing which may be contaminated, in a vapor-tight plastic bag for eventual disposal. Wash any surfaces you may have contaminated with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT: Not available

-EMERGENCY PROCEDURES
==========

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. Volatile chemicals have a high risk of being aspirated into the victim's lungs during vomiting which increases the medical problems.
If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a hospital or poison control center. IMMEDIATELY transport the victim to a hospital.
If the victim is convulsing or unconscious, do not give anything by mouth, ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport

the victim to a hospital.

*SYMPTOMS:

Symptoms of exposure to this compound include irritation of the skin, eyes, nose, throat and respiratory tract, dizziness, nausea, central nervous system depression, dizziness, giddiness and headache [058]. It can cause flushing, decrease in pulse rate, lowered blood pressure, anesthesia, narcosis, mental depression, hallucinations, distorted perceptions, dyspnea, respiratory depression, vomiting, corneal burns, eye damage and coma [043]. It can also cause abdominal pain, hematemesis, areflexia, oliguria followed by diuresis, generalized tenderness, induration and edema of muscles. Prolonged skin contact may cause corrosion [301]. Drunkenness may also occur [371].

HAZARDOUS SUBSTANCE FACT SHEET

Common Name: **ISOPROPYL ALCOHOL**

CAS Number: 67-63-0
DOT Number: UN 1219

RTK Substance number: 1076
Date: February 1989 Revision: January 1997

HAZARD SUMMARY

* **Isopropyl Alcohol** can affect you when breathed in and by passing through your skin.
* There is an increased risk of cancer associated with the manufacture of **Isopropyl Alcohol**.
* Contact can irritate and burn the skin and eyes. Repeated skin exposure can cause itching, rash, drying and cracking.
* Breathing **Isopropyl Alcohol** can irritate the nose and throat.
* Overexposure can cause headache, drowsiness, unconsciousness and death.
* **Isopropyl Alcohol** is a FLAMMABLE LIQUID and a FIRE HAZARD.

IDENTIFICATION

Isopropyl Alcohol is a colorless liquid. It is used as a solvent and in making many commercial products. *Rubbing alcohol* is a solution of **Isopropyl Alcohol**.

REASON FOR CITATION

* **Isopropyl Alcohol** is on the Hazardous Substance List because it is regulated by OSHA and cited by ACGIH, DOT, NFPA and NIOSH.
* This chemical is on the Special Health Hazard Substance List because it is **FLAMMABLE**.
* Definitions are provided on page 5.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

The New Jersey Right to Know Act requires most employers to label chemicals in the workplace and requires public employers to provide their employees with information and training concerning chemical hazards and controls. The federal OSHA Hazard Communication Standard, 1910.1200, requires private employers to provide similar training and information to their employees.

* Exposure to hazardous substances should be routinely evaluated. This may include collecting air samples. Under OSHA 1910.20, you have a legal right to obtain copies of sampling results from your employer.
* If you think you are experiencing any work-related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.

---

* **ODOR THRESHOLD = 22 ppm**.
* The range of accepted odor threshold values is quite broad. Caution should be used in relying on odor alone as a warning of potentially hazardous exposures.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is **400 ppm** averaged over an 8-hour workshift.

NIOSH: The recommended airborne exposure limit is **400 ppm** averaged over a 10-hour workshift and **500 ppm** not to be exceeded during any 15 minute work period.

ACGIH: The recommended airborne exposure limit is **400 ppm** averaged over an 8-hour workshift and **500 ppm** as a STEL (short term exposure limit).

* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* Wear protective work clothing.
* Wash thoroughly immediately after exposure to **Isopropyl Alcohol** and at the end of the workshift.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of **Isopropyl Alcohol** to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to **Isopropyl Alcohol**:

* Contact can irritate and burn the skin and eyes.
* Breathing **Isopropyl Alcohol** can irritate the nose and throat.
* Overexposure can cause headache, drowsiness, a loss of coordination, unconsciousness and death.

Chronic Health Effects

The following chronic (long-term) health effects can occur at some time after exposure to **Isopropyl Alcohol** and can last for months or years:

Cancer Hazard

* There is an increased incidence of nasal sinus cancer in workers involved in the manufacture of **Isopropyl Alcohol** by the strong-acid process. However, **Isopropyl Alcohol** has been tested and has not been shown to cause cancer in animals.

Reproductive Hazard

* According to the information presently available to the New Jersey Department of Health and Senior Services, **Isopropyl Alcohol** has been tested and has not been shown to affect reproduction.

Other Long-Term Effects

* Repeated skin exposure can cause itching, redness, rash, drying and cracking.
* This chemical has not been adequately evaluated to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum-based chemicals have been shown to cause such damage. Effects may include reduced memory and concentration, personality changes (withdrawal, irritability), fatigue, sleep disturbances, reduced coordination, and/or effects on nerves supplying internal organs (autonomic nerves) and/or nerves to the arms and legs (weakness, "pins and needles").

MEDICAL

Medical Testing

If symptoms develop or overexposure is suspected, the following may be useful:

* There is no special test for this chemical. However, if illness occurs or overexposure is suspected, medical attention is recommended.
* Interview for brain effects, including recent memory, mood (irritability, withdrawal), concentration, headaches, malaise and altered sleep patterns. Consider cerebellar, autonomic and peripheral nervous system evaluation. Positive and borderline individuals should be referred for neuropsychological testing.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

Request copies of your medical testing. You have a legal right to this information under OSHA 1910.20.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, **ENGINEERING CONTROLS** are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the controls mentioned above, but is sometimes necessary.

In evaluating the controls present in your workplace, consider: (1) how hazardous the substance is, (2) how much of the substance is released into the workplace and (3) whether harmful skin or eye contact could occur. Special controls should be in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically pump liquid **Isopropyl Alcohol** from drums or other storage containers to process containers.
* Specific engineering controls are recommended for this chemical by NIOSH. Refer to the NIOSH criteria document: *Isopropyl Alcohol #76-142*.
* Before entering a confined space where **Isopropyl Alcohol** may be present, check to make sure that an explosive concentration does not exist.

Good **WORK PRACTICES** can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by **Isopropyl Alcohol** should change into clean clothing promptly.
* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to **Isopropyl Alcohol**.
* On skin contact with **Isopropyl Alcohol**, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted **Isopropyl Alcohol**, whether or not known skin contact has occurred.
* Do not eat, smoke, or drink where **Isopropyl Alcohol** is handled, processed, or stored, since the chemical can be swallowed. Wash hands carefully before eating or smoking.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT. However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with **Isopropyl Alcohol**. Wear solvent-resistant gloves and clothing. Safety equipment suppliers/manufacturers can provide recommendations on the most protective glove/clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.
* ACGIH recommends *Natural Rubber, Neoprene, Nitrile* or *Polyvinyl Chloride* as protective materials.

Eye Protection

* Wear splash-proof chemical goggles and face shield when working with liquid, unless full facepiece respiratory protection is worn.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* Where the potential exists for exposures over **400 ppm**, use a MSHA/ NIOSH approved full facepiece respirator with an organic vapor cartridge/canister. Even greater protection is provided by a powered-air purifying respirator.
* If while wearing a filter, cartridge or canister respirator, you can smell, taste, or otherwise detect **Isopropyl Alcohol**, or in the case of a full facepiece respirator you experience eye irritation, leave the area immediately. Check to make sure the respirator-to-face seal is still good. If it is, replace the filter, cartridge, or canister. If the seal is no longer good, you may need a new respirator.
* Be sure to consider all potential exposures in your workplace. You may need a combination of filters, prefilters, cartridges, or canisters to protect against different forms of a chemical (such as vapor and mist) or against a mixture of chemicals.
* Where the potential for high exposures exists, use a MSHA/NIOSH approved supplied-air respirator with a full facepiece operated in a pressure-demand or other positive-pressure mode. For increased protection use in combination with an auxiliary self-contained breathing apparatus operated in a pressure-demand or other positive-pressure mode.
* Exposure to **2,000 ppm** is immediately dangerous to life and health. If the possibility of exposure above **2,000 ppm** exists, use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in continuous flow or other positive pressure mode.

HANDLING AND STORAGE

* Prior to working with **Isopropyl Alcohol** you should be trained on its proper handling and storage.
* **Isopropyl Alcohol** must be stored to avoid contact with STRONG OXIDIZERS (such as CHLORINE, BROMINE and FLUORINE) since violent reactions occur.

* Store in tightly closed containers in a cool, well-ventilated area away from HEAT.
* Sources of ignition, such as smoking and open flames, are prohibited where **Isopropyl Alcohol** is used, handled, or stored in a manner that could create a potential fire or explosion hazard.
* Metal containers involving the transfer of **Isopropyl Alcohol** should be grounded and bonded.
* Use only non-sparking tools and equipment, especially when opening and closing containers of **Isopropyl Alcohol**.

QUESTIONS AND ANSWERS

Q: If I have acute health effects, will I later get chronic health effects?
A: Not always. Most chronic (long-term) effects result from repeated exposures to a chemical.

Q: Can I get long-term effects without ever having short-term effects?
A: Yes, because long-term effects can occur from repeated exposures to a chemical at levels not high enough to make you immediately sick.

Q: What are my chances of getting sick when I have been exposed to chemicals?
A: The likelihood of becoming sick from chemicals is increased as the amount of exposure increases. This is determined by the length of time and the amount of material to which someone is exposed.

Q: When are higher exposures more likely?
A: Conditions which increase risk of exposure include physical and mechanical processes (heating, pouring, spraying, spills and evaporation from large surface areas such as open containers), and "confined space" exposures (working inside vats, reactors, boilers, small rooms, etc.).

Q: Is the risk of getting sick higher for workers than for community residents?
A: Yes. Exposures in the community, except possibly in cases of fires or spills, are usually much lower than those found in the workplace. However, people in the community may be exposed to contaminated water as well as to chemicals in the air over long periods. Because of this, and because of exposure of children or people who are already ill, community exposures may cause health problems.

The following information is available from:

New Jersey Department of Health and
Senior Services
Occupational Disease and Injury Services
Trenton, NJ 08625-0360
(609) 984-1863

Industrial Hygiene Information

Industrial hygienists are available to answer your questions regarding the control of chemical exposures using exhaust ventilation, special work practices, good housekeeping, good hygiene practices, and personal protective equipment including respirators. In addition, they can help to interpret the results of industrial hygiene survey data.

Medical Evaluation

If you think you are becoming sick because of exposure to chemicals at your workplace, you may call a Department of Health and Senior Services physician who can help you find the services you need.

Public Presentations

Presentations and educational programs on occupational health or the Right to Know Act can be organized for labor unions, trade associations and other groups.

Right to Know Information Resources

The Right to Know Infoline (609) 984-2202 can answer questions about the identity and potential health effects of chemicals, list of educational materials in occupational health, references used to prepare the Fact Sheets, preparation of the Right to Know survey, education and training programs, labeling requirements, and general information regarding the Right to Know Act. Violations of the law should be reported to (609) 984-2202.

DEFINITIONS

ACGIH is the American Conference of Governmental Industrial Hygienists. It recommends upper limits (called TLVs) for exposure to workplace chemicals.

A **carcinogen** is a substance that causes cancer.

The **CAS number** is assigned by the Chemical Abstracts Service to identify a specific chemical.

A **combustible** substance is a solid, liquid or gas that will burn.

A **corrosive** substance is a gas, liquid or solid that causes irreversible damage to human tissue or containers.

DEP is the New Jersey Department of Environmental Protection.

DOT is the Department of Transportation, the federal agency that regulates the transportation of chemicals.

EPA is the Environmental Protection Agency, the federal agency responsible for regulating environmental hazards.

A **fetus** is an unborn human or animal.

A **flammable** substance is a solid, liquid, vapor or gas that will ignite easily and burn rapidly.

The **flash point** is the temperature at which a liquid or solid gives off vapor that can form a flammable mixture with air.

HHAG is the Human Health Assessment Group of the federal EPA.

IARC is the International Agency for Research on Cancer, a scientific group that classifies chemicals according to their cancer-causing potential.

A **miscible** substance is a liquid or gas that will evenly dissolve in another.

mg/m^3 means milligrams of a chemical in a cubic meter of air. It is a measure of concentration (weight/volume).

MSHA is the Mine Safety and Health Administration, the federal agency that regulates mining. It also evaluates and approves respirators.

A **mutagen** is a substance that causes mutations. A **mutation** is a change in the genetic material in a body cell. Mutations can lead to birth defects, miscarriages, or cancer.

NAERG is the North American Emergency Response Guidebook. It was jointly developed by Transport Canada, the United States Department of Transportation and the Secretariat of Communications and Transportation of Mexico. It is a guide for first responders to quickly identify the specific or generic hazards of material involved in a transportation incident, and to protect themselves and the general public during the initial response phase of the incident.

NCI is the National Cancer Institute, a federal agency that determines the cancer-causing potential of chemicals.

NFPA is the National Fire Protection Association. It classifies substances according to their fire and explosion hazard.

NIOSH is the National Institute for Occupational Safety and Health. It tests equipment, evaluates and approves respirators, conducts studies of workplace hazards, and proposes standards to OSHA.

NTP is the National Toxicology Program which tests chemicals and reviews evidence for cancer.

OSHA is the Occupational Safety and Health Administration, which adopts and enforces health and safety standards.

PEOSHA is the Public Employees Occupational Safety and Health Act, a state law which sets PELs for New Jersey public employees.

ppm means parts of a substance per million parts of air. It is a measure of concentration by volume in air.

A **reactive** substance is a solid, liquid or gas that releases energy under certain conditions.

A **teratogen** is a substance that causes birth defects by damaging the fetus.

TLV is the Threshold Limit Value, the workplace exposure limit recommended by ACGIH.

The **vapor pressure** is a measure of how readily a liquid or a solid mixes with air at its surface. A higher vapor pressure indicates a higher concentration of the substance in air and therefore increases the likelihood of breathing it in.

>>>>>>>>>>>>>>>>> E M E R G E N C Y I N F O R M A T I O N <<<<<<<<<<<<<<<<<

Common Name: **ISOPROPYL ALCOHOL**
DOT Number: **UN 1219**
NAERG Code: **129**
CAS Number: **67-63-0**

Hazard rating	NJ DOH	NFPA
FLAMMABILITY	-	3
REACTIVITY	-	0
POISONOUS GASES ARE PRODUCED IN FIRE CONTAINERS MAY EXPLODE IN FIRE		

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* **Isopropyl Alcohol** is a FLAMMABLE LIQUID.
* Vapors may travel to a source of ignition and flash back.
* CONTAINERS MAY EXPLODE IN FIRE.
* Use dry chemical, CO_2, water spray, or alcohol foam extinguishers.
* POISONOUS GASES ARE PRODUCED IN FIRE.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If **Isopropyl Alcohol** is spilled or leaked, take the following steps:

* Restrict persons not wearing protective equipment from area of spill or leak until clean-up is complete.
* Remove all ignition sources.
* Ventilate area of spill or leak.
* Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.
* Keep **Isopropyl Alcohol** out of a confined space, such as a sewer, because of the possibility of an explosion, unless the sewer is designed to prevent the build-up of explosive concentrations.
* It may be necessary to contain and dispose of **Isopropyl Alcohol** as a HAZARDOUS WASTE. Contact your Department of Environmental Protection (DEP) or your regional office of the federal Environmental Protection Agency (EPA) for specific recommendations.
* If employees are required to clean-up spills, they must be properly trained and equipped. OSHA 1910.120(q) may be applicable.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department. You can request emergency information from the following:

CHEMTREC: (800) 424-9300
NJDEP HOTLINE: (609) 292-7172

==========

HANDLING AND STORAGE (See page 3)

FIRST AID

In NJ, POISON INFORMATION 1-800-962-1253

Eye Contact

* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids.

Skin Contact

* Quickly remove contaminated clothing. Immediately wash contaminated skin with large amounts of water.

Breathing

* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

PHYSICAL DATA

Vapor Pressure: 33 mm Hg at 68^{o}F (20^{o}C)
Flash Point: 53^{o}F (11.6^{o}C)
Water Solubility: Miscible

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

ISOPROPYL ALCOHOL (STRONG-ACID PROCESS) (EDF-377)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards** **Reference(s)**
  Recognized: --
  Suspected: Carcinogen IARC
  Neurotoxicant EPA-SARA
- **Hazard Rankings**
  Data lacking; not ranked by any system in Scorecard.
- **Chemical Use Profile**
  No data on industrial or consumer use in Scorecard.
- **Profile of Environmental Release and Waste Generation**
  No data on environmental releases in Scorecard.
- **Regulatory Coverage**
  Not on chemical lists in Scorecard.
- **Basic Testing to Identify Chemical Hazards**
  Information on whether basic tests to identify chemical hazards have been conducted on this chemical is not available.
- **Information Needed for Safety Assessment**
  Lacks at least some of the national data required for safety assessment.
  No data on risk assessment values in Scorecard.
- **Links**
  Other web sites specific to this chemical:

  - CalEPA Air Resources Board Toxic Air Contaminant Summary
  - IPCS International Chemical Safety Card
  - National Toxicology Program Health and Safety Information Sheet
  - New Jersey Fact Sheet

  If none of these sources meet your needs, you can try searching some other chemical database Web sites.

- **Notes**

TRI release and waste generation data are not available even though this compound is covered by TRI reporting requirements because the strong acid manufacturing process is no longer in use anywhere in the U.S.

ETHYLBENZENE (100-41-4)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards**

		Reference(s)
Recognized:	--	
Suspected:	Cardiovascular or Blood Toxicant	RTECS
	Developmental Toxicant	EPA-HEN EPA-SARA OEHHA-2000
	Endocrine Toxicant	OEHHA-2000
	Gastrointestinal or Liver Toxicant	OEHHA-2000 RTECS
	Kidney Toxicant	OEHHA-2000 RTECS
	Neurotoxicant	DAN EPA-HEN RTECS
	Reproductive Toxicant	EPA-SARA
	Respiratory Toxicant	EPA-HEN RTECS
	Skin or Sense Organ Toxicant	EPA-HEN RTECS

- **Hazard Rankings**

  More hazardous than most chemicals in 3 out of 10 ranking systems.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.
  Used in at least 6 industries.
  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.

- **Profile of Environmental Release and Waste Generation**

  For a list of the geographic areas, facilities, or industrial sectors which report the largest releases or transfers of this chemical to the Toxics Release Inventory, select what you want:

  - Rank States
  - Rank Counties
  - Rank Zip Codes
  - Rank Facilities
  - Rank Industrial Sectors

- **Regulatory Coverage**

  On at least 6 federal regulatory lists.

- **Basic Testing to Identify Chemical Hazards**

  Eight basic tests to identify chemical hazards have been conducted and are publicly

available for this chemical.

- **Information Needed for Safety Assessment**

  Possesses all the national data required for safety assessment.
  Scorecard has risk assessment data for this chemical.

- **Links**

  Additional information about this chemical may be available elsewhere in Scorecard.

Endocrine Toxicity Definition

from the Health Effects section of Scorecard

Endocrine toxicity is defined as adverse effects on the structure and /or functioning of the endocrine system that result from exposure to chemical substances. The endocrine system is composed of many organs and glands that secrete hormones directly into the bloodstream, including the pituitary, hypothalamus, thyroid, adrenals, pancreas, thymus, ovaries, and testes. Once synthesized, hormones are conveyed to a target tissue, where they function as chemical messengers that transmit information between cells. Hormone levels and interactions control normal physiological processes, maintaining the body's homeostasis. Because the endocrine system is complex, a toxicant may interfere at any of a number of points along a hormone's pathway of production, regulation, and action. Some chemicals may injure the glands that synthesize and secrete hormones, while others disrupt hormonal actions at the target organ. Compounds that are toxic to the endocrine system may cause diseases such as hypothyroidism, diabetes mellitus, hypoglycemia, reproductive disorders, and cancer.

A wide variety of toxic substances can disrupt the function of the endocrine system. For example, chemicals that resemble the hormone estrogen can bind to estrogen receptors located throughout the body and either mimic the natural hormone or inhibit its actions. Exposure to endocrine-disrupting chemicals such as polychlorinated biphenyls (PCBs) and DDT have caused a host of toxic effects in wildlife, including impaired reproduction and development. Other endocrine toxicants, such as persistent organochlorine pesticides and dioxins, are being studied for their possible role in promoting hormone-induced cancers (such as breast cancer) and in lowering sperm counts and male fertility.

Specific organs and glands in the endocrine system are known to be damaged by chemical toxicants. Several chemicals and drugs can be toxic to the cells of the pancreas that produce insulin. Exposure to the rodenticide Vacor (N-3-pyridylmethyl-N'-p-nitrophenyl urea) can interfere with the secretion and function of pancreatic hormones, resulting in diabetes mellitus and hyperglycemia. Polyhydroxyphenols and the therapeutic drug lithium can disrupt thyroid gland function and cause hypothyroidism and goiter. Endocrine and reproductive dysfunction have been reported in men exposed to inorganic lead. Chronic exposure to lead can cause direct testicular toxicity, followed by hypothalamic or pituitary gland disturbances.

Industrial Uses

for ETHYLBENZENE (100-41-4) from Scorecard

This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.

Which Industries Use This Chemical?	**How is the Chemical Used in This Industry?**
Electroplating	Electroplating - Vapor Degreasing Solvents
Machinery Mfg and Repair	Solvents - Machinery Manufacture and Repair
Paint Manufacture	Hydrocarbon Solvents
Paper Coating	Solvents
Rubber Manufacture	Solvents - Rubber Manufacture
Wood Stains and Varnishes	Varnish Solvents

Consumer Products

that contain ETHYLBENZENE (100-41-4) from Scorecard

What kinds of consumer products may contain this chemical?

- Aerosol paint concentrates
- Agricultural chemicals
- Auto, other transportation, and machinery refinish paints incl primers
- Automobile body polish and cleaners
- Bathroom tub and tile cleaners
- Building and construction plastic foam insulation, incl pipe and block
- Floor polish
- Furniture polish and cleaners
- Ground/traffic marking coatings
- Herbicides for agric., garden and health service use
- Insecticides for agric., garden and health service use
- Insecticides for crawling insects
- Insecticides for flying insects
- Laundry starch preparations
- Loose mineral wool fiber (blowing and pouring)
- Miscellaneous paint-related products
- Nonstructural caulking compounds and sealants
- Other automotive chemicals
- Other rubber floor and wall coverings incl cove base, wainscotting, etc.
- Other specialty cleaning and sanitation products
- Oven cleaners
- Paint and varnish removers
- Paint thinners
- Rug and upholstery cleaners
- Scatter rugs, bathmats, and sets (rugs 6 x 9 ft and smaller)
- Sheet vinyl flooring
- Solvent thinned exterior stains incl shingle and shake
- Solvent thinned exterior undercoaters and primers
- Solvent thinned interior clear finishes
- Solvent thinned interior stains
- Solvent thinned interior undercoaters and primers
- Waterproofing compounds

- Wood office furniture

Basic Testing to Identify Chemical Hazards

for ETHYLBENZENE (100-41-4) from Scorecard

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

Eight basic tests to identify chemical hazards have been conducted and are publicly available for this chemical.

More on the importance of basic toxicity testing

Agency for Toxic Substances and Disease Registry

Public Health Statement

Ethylbenzene

ATSDR Public Health Statement, December 1990

This Statement was prepared to give you information about ethylbenzene and to emphasize the human health effects that may result from exposure to it. The Environmental Protection Agency (EPA) has identified 1,177 sites on its National Priorities List (NPL). Ethylbenzene has been found at 227 of these sites. However, we do not know how many of the 1,177 NPL sites have been evaluated for ethylbenzene. As EPA evaluates more sites, the number of sites at which ethylbenzene is found may change. The information is important for you because ethylbenzene may cause harmful health effects and because these sites are potential or actual sources of human exposure to ethylbenzene.

When a chemical is released from a large area, such as an industrial plant, or from a container, such as a drum or bottle, it enters the environment as a chemical emission. This emission, which is also called a release, does not always lead to exposure. You can be exposed to a chemical only when you come into contact with the chemical. You may be exposed to it in the environment by breathing, eating, or drinking substances containing the chemical or from skin contact with it.

If you are exposed to a hazardous substance such as ethylbenzene, several factors will determine whether harmful health effects will occur and what the type and severity of those health effects will be. These factors include the dose (how much), the duration (how long), the route or pathway by which you are exposed (breathing, eating, drinking, or skin contact), the other chemicals to which you are exposed, and your individual characteristics such as age, sex, nutritional status, family traits, life style, and state of health.

What is ethylbenzene?

Ethylbenzene is a colorless liquid that smells like gasoline. It evaporates at room temperature and burns easily. Ethylbenzene occurs naturally in coal tar and petroleum. It is also found in many man-made products, including paints, inks, and insecticides. Gasoline contains about 2% (by weight) ethylbenzene. It is most commonly found as a vapor in the air. This is because ethylbenzene moves easily into the air from water and soil. Once in the air, other chemicals help break down ethylbenzene into chemicals found in smog. This breakdown happens in about 3 days with the aid of sunlight. In surface water such as rivers

and harbors, ethylbenzene breaks down by reacting with other compounds naturally present in the water. In soil, the major way ethylbenzene is broken down is by soil bacteria. It can also move very quickly into groundwater, since it does not readily bind to soil. Near hazardous waste sites, the levels of ethylbenzene in the air, water, and soil could be much higher than in other areas.

How might I be exposed to ethylbenzene?

There are a variety of ways you may be exposed to this chemical. If you live in a highly populated area or near many factories or heavily traveled highways, you may be exposed to ethylbenzene in the air. Releases of ethylbenzene into these areas occur from burning oil, gas, and coal and from discharges of ethylbenzene from some types of factories. The median level of ethylbenzene in city air is about 0.62 parts of ethylbenzene per billion parts (ppb) of air. The median level in suburban air is about 0.62 ppb. In contrast, the median level of ethylbenzene measured in air in country locations is about 0.01 ppb. Indoor air has a higher median concentration of ethylbenzene (about 1 ppb) than outdoor air. This is because ethylbenzene builds up after you use household products such as cleaning products or paints.

Ethylbenzene was found in only 1 out of 10 of the United States rivers and streams tested in 1982 and 1983. The average level measured was 5.0 ppb. Ethylbenzene gets into water from factory releases, boat fuel, and poor disposal of waste. Background levels in soils have not been reported. Ethylbenzene may get into the soil by gasoline or other fuel spills and poor disposal of industrial and household wastes.

Some people are exposed to ethylbenzene in the workplace. Gas and oil workers may come into contact with ethylbenzene either through the skin or by breathing ethylbenzene vapors. Varnish workers, spray painters and persons involved in gluing operations may also be exposed to high levels of ethylbenzene. Exposure may also occur in factories that use ethylbenzene to produce other chemicals. Families of these workers may be exposed to ethylbenzene through contact with contaminated clothing.

You may be exposed to ethylbenzene if you live near hazardous waste sites containing ethylbenzene or areas where ethylbenzene spills have occurred. Higher than background levels of ethylbenzene were detected in groundwater near a landfill and near an area where a fuel spill had occurred. No specific information on human exposure to ethylbenzene near hazardous waste sites is available.

You may also be exposed to ethylbenzene from the use of many consumer products. Gasoline is a common source of ethylbenzene exposure. Other sources of ethylbenzene exposure come from the use of this chemical as a solvent in pesticides, carpet glues, varnishes and paints, and from the use of tobacco products. Ethylbenzene does not generally build up in food. However, some vegetables may contain very small amounts of it.

How can ethylbenzene enter and leave my body?

When you breathe air containing ethylbenzene vapor, it enters your body rapidly and almost completely through your lungs. Ethylbenzene in food or water can also rapidly and almost completely enter your body through the digestive tract. It may enter through your skin when you come into contact with liquids containing ethylbenzene. Ethylbenzene vapors do not enter through your skin to any large degree. People living in urban areas or in areas near hazardous waste sites may be exposed by breathing air or by drinking water contaminated with ethylbenzene.

Once in your body, ethylbenzene is broken down into other chemicals. Most of it leaves in the urine within 2 days. Small amounts can also leave through the lungs and in feces. Liquid ethylbenzene also enters through your skin and is broken down. Ethylbenzene in high levels is broken down slower in your body than low levels of ethylbenzene. Similarly, ethylbenzene mixed with other solvents is also broken down more slowly than ethylbenzene alone. This slower breakdown may increase the time it takes for ethylbenzene to leave your body.

How can ethylbenzene affect my health?

At certain levels, exposure to ethylbenzene can harm your health. People exposed to low levels of ethylbenzene in the air for short periods of time have complained of eye and throat irritation. Persons exposed to higher levels have shown signs of more severe effects such as decreased movement and dizziness. No studies have reported death in humans following exposure to ethylbenzene. However, evidence from animals suggests that it can cause death at very high concentrations. Whether or not long-term exposure to ethylbenzene affects human health is not known because little information is available. Short-term exposure of laboratory animals to high concentrations of ethylbenzene in air may cause liver and kidney damage, nervous system changes, and blood changes. The link between these health effects and exposure to ethylbenzene is not clear because of conflicting results and weaknesses in many of the studies.

Also, there is no clear evidence that the ability to get pregnant is affected by breathing air, drinking water containing ethylbenzene, or coming into direct contact with ethylbenzene through the skin. Birth defects have occurred in newborn animals whose mothers were exposed by breathing air contaminated with ethylbenzene. The seriousness of these effects seems to increase with higher exposure levels. One long-term study in animals suggests that ethylbenzene may cause tumors. However, this study had many weaknesses and no conclusions could be drawn about possible cancer effects in humans. EPA has determined that ethylbenzene is not classifiable as to human carcinogenicity.

What levels of exposure have resulted in harmful health effects?

Low levels of ethylbenzene in the air may cause harmful health effects. More serious effects to your health may occur at higher levels. You can smell ethylbenzene in the air at concentrations as low as 2 parts of ethylbenzene per million parts of air by volume (ppm).

There are no reliable data on the effects in humans after eating, drinking, or breathing ethylbenzene or following direct exposure to the skin. For this reason, levels of exposure that may affect your health are estimated from animal studies. Only two reports described the results of eye or skin exposure to ethylbenzene. In these studies, liquid ethylbenzene caused eye damage and skin irritation in rabbits. More animal studies are available that describe the effects of breathing air or drinking water containing ethylbenzene. Tables 1-1, 1-2, 1-3, and 1-4 show the relationship between exposure to ethylbenzene in air, food, or water and known health effects.

A Minimal Risk Level (MRL) is also included in Table 1-1. This MRL was derived from animal data for

long-term exposure. The MRL provides a basis for comparison with levels that people might encounter either in the air, in food, or in drinking water. If a person is exposed to ethylbenzene at an amount below the MRL, it is not expected that harmful (noncancer) health effects will occur. Because this level is based only on information currently available, some uncertainty is always associated with it. Also, because the method for deriving MRLs does not use any information about cancer, an MRL does not imply anything about the presence, absence, or level of risk for cancer.

Is there a medical test to determine whether I have been exposed to ethylbenzene?

Ethylbenzene is found in the blood, urine, breath, and some body tissues of exposed persons. Urine is most commonly tested to determine exposure to ethylbenzene. The test measures the presence of substances formed following an exposure to ethylbenzene. These substances are formed by the breakdown of ethylbenzene. You should have this test done within a few hours after exposure occurs, because these substances leave the body very quickly. Although this test can prove your exposure to ethylbenzene, it cannot yet predict the kind of health effects that might develop from that exposure.

What recommendations has the federal government made to protect human health?

The federal government has formed regulatory standards and guidelines to protect you from possible health effects of ethylbenzene in the environment. EPA's Office of Drinking Water (ODW) recommends 680 ppb (0.68 mg/L) as the acceptable exposure concentration of ethylbenzene in drinking water for an average weight adult. This value is for lifetime exposure and is not expected to increase the chance of experiencing (noncancer) health effects. The same EPA office (ODW) recommends higher acceptable levels of ethylbenzene in water for shorter periods (32,000 ppb or 32 mg/L for 1 day, 3,200 ppb or 3.2 mg/L for 10 days). These levels are stated to be acceptable for small children. EPA also recommends that if you eat fish and drink water from a body of water, the water should contain no more than 1.4 mg ethylbenzene/L.

EPA requires that a release of 1,000 pounds or more of ethylbenzene be reported to the Federal Government National Response Center in Washington, D.C.

The Occupational Safety and Health Administration (OSHA) set a legal limit of 100 ppm ethylbenzene in air. This is for exposure at work for 8 hours per day. OSHA also set a limit of 125 ppm for a 15-minute period.

The National Institute for Occupational Safety and Health (NIOSH) also recommends an exposure limit for ethylbenzene of 100 ppm. This is for exposure to ethylbenzene in air at work for up to 10 hours per day in a 40-hour work week. NIOSH classifies ethylbenzene exposures of 2,000 ppm in air as immediately dangerous to life or health.

Where can I get more information?

If you have any more questions or concerns not covered here, please contact your state health or environmental department or:

Agency for Toxic Substances and Disease Registry
Division of Toxicology
1600 Clifton Road, E-29
Atlanta, Georgia 30333

This agency can also give you information on the location of the nearest occupational and environmental health clinics. Such clinics specialize in recognizing, evaluating, and treating illnesses that result from exposure to hazardous substances.

ETHYL BENZENE

Ethyl benzene is a federal hazardous air pollutant and was identified as a toxic air contaminant in April 1993 under AB 2728.

CAS Registry Number: 100-41-4

Molecular Formula: C_8H_{10}

Description

Ethyl benzene is a colorless, flammable liquid with an aromatic odor. It is practically insoluble in water and is soluble in alcohol, carbon tetrachloride, ether, and other organic solvents. Ethyl benzene evaporates about 94 times more slowly than ether (HSDB, 1991).

Physical Properties of Ethyl benzene

Molecular Weight	106.16
Boiling Point	136.2 oC
Melting Point	-94.97 oC
Flash Point	18 oC (closed cup)
Vapor Density	3.66 (air = 1)
Vapor Pressure	9.53 mm Hg at 25 oC
Density/Specific Gravity	0.867 at 20/4 oC (water = 1)
Log Octanol/Water Partition Coefficient	3.15
Conversion Factor	1 ppm = 4.34 mg/m3

(Howard, 1990; HSDB, 1991; Merck, 1989; Sax, 1987; U.S. EPA, 1994a)

SOURCES AND EMISSIONS

A. Sources

Ethyl benzene is used as an intermediate in the production of styrene and as a solvent in paint and other consumer products. Ethyl benzene is also used in petroleum refining. Ethyl benzene has been detected in auto emissions and cigarette smoke (Howard, 1990).

The primary stationary sources that have reported emissions of ethyl benzene in California are manufacturers of aircraft and parts, petroleum refining, and manufacturers of miscellaneous plastics products (ARB, 1997b). Ethyl benzene has also been detected but not quantified in motor vehicle exhaust by the Air Resources Board (ARB) (ARB, 1995e).

B. Emissions

The total emissions of ethyl benzene from stationary sources in California are estimated to be at least 140,000 pounds per year, based on data reported under the Air Toxics "Hot Spots" Program (AB 2588) (ARB, 1997b).

C. Natural Occurrence

Ethyl benzene is a component of crude oil (HSDB, 1991).

AMBIENT CONCENTRATIONS

Ethyl benzene is routinely monitored by the statewide ARB air toxics network. The network's mean concentration of ethyl benzene from January 1996 through December 1996 is estimated to be 1.61 micrograms per cubic meter (µg/m3) or 0.37 parts per billion (ppb) (ARB, 1997c).

The United States Environmental Protection Agency (U.S. EPA) has also compiled ambient concentration data from several studies throughout the United States. Data from 11 United States cities during 1990 reported an overall mean concentration of 1.68 µg/m3 (0.39 ppb) (U.S. EPA, 1993a).

INDOOR SOURCES AND CONCENTRATIONS

Ethyl benzene is a chemical solvent found in many consumer products such as paint and cleaning products. However, ethyl benzene comprises less than 10 percent by weight of the product ingredients in these products (Sack and Steele, 1989).

Ethyl benzene was measured in Los Angeles homes during winter and summer seasons in the 1987 Total Exposure Assessment Methodology study (Pellizzari et al., 1989). The mean indoor concentrations of ethyl benzene were 5.02 to 6.64 µg/m3 and 2.48 to 3.03 µg/m3 for winter and summer, respectively. In contrast, the mean outdoor concentrations of ethyl benzene were 4.58 µg/m3 and 1.61 µg/m3 for winter and summer, respectively.

In a study of east coast public buildings, the average indoor concentrations of ethyl benzene ranged from 3.6 to 6.8 µg/m3 (Sheldon et al, 1988a). In other public buildings, the mean concentrations of ethyl benzene for most of the indoor environments ranged from 1.01 to 10.15 µg/m3 except for a new office with a high mean concentration of 51.26 µg/m3 (Sheldon et al, 1988b).

Studies in Raleigh, North Carolina and Boston, Massachusetts measured average in-vehicle concentrations of ethyl benzene of 5.8 µg/m3 and 8.8 µg/m3 and maximum concentrations of 21.6 µg/m3 and 21.8 µg/m3, respectively; about 3 to 5 times greater than what was measured in the ambient air (Chan et al., 1991a; Chan et al., 1991b).

ATMOSPHERIC PERSISTENCE

The only important chemical loss process for ethyl benzene in the troposphere is by the reaction with the hydroxyl (OH) radical. The calculated half-life and lifetime of ethyl benzene due to reaction with the OH radical are 1.4 days and 2.0 days, respectively. The reaction products are expected to include ethylphenols, acetophenone, glyoxal, ethylglyoxal, and other ring-opened products (Atkinson, 1995). Its reaction products include glyoxal, ethylglyoxal, acetophenone, formaldehyde, and acetaldehyde (Kao, 1994).

AB 2588 RISK ASSESSMENT INFORMATION

Although ethyl benzene is reported as being emitted in California from stationary sources no health values (cancer or non-cancer) are listed in the California Air Pollution Control Officers Association Air Toxics "Hot Spots" Program Revised 1992 Risk Assessment Guidelines for use in risk assessments (CAPCOA, 1993).

HEALTH EFFECTS

Probable routes of human exposure to ethyl benzene are inhalation and ingestion (HSDB, 1991).

Non-Cancer: Ethyl benzene is a central nervous system depressant at high levels of exposure. Ethyl benzene is also irritating to the eyes and respiratory tract. Animal studies have shown effects on the blood, liver and kidneys from chronic inhalation exposure to ethyl benzene (U.S. EPA, 1994a). Persons with existing skin disorders, liver, kidney, nervous system, blood and hemopoietic-organ disorders, and women with ovulation and menstrual cycle disorders may be more susceptible to adverse effects (HSDB, 1991).

The U.S. EPA has established a Reference Concentration (RfC) of 1 milligram per cubic meter for ethyl benzene based on developmental toxicity in rats and rabbits. The U.S. EPA estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic, non-cancer effects. The U.S. EPA has established an oral Reference Dose (RfD) of 0.1 milligrams per kilogram per day for ethyl benzene based on liver and kidney toxicity in rats. The U.S. EPA estimates that consumption of this dose or less, over a lifetime, will not result in the occurrence of chronic, non-cancer effects (U.S. EPA, 1994a).

No adverse human reproductive information is available. Adverse effects in fetal development have been reported in animal inhalation studies (U.S. EPA, 1994a).

Cancer: Limited and inconclusive data are available regarding the carcinogenic effects of ethyl benzene in humans and animals. The U.S. EPA has classified ethyl benzene as Group D: Not classifiable as to human carcinogenicity (U.S. EPA, 1994a). The International Agency for Research on Cancer has not classified ethyl benzene as to its carcinogenicity (IARC, 1987a).

Hazard Summary

CAUTION: Unless otherwise noted, the quantitative information on these fact sheets are from "EPA Health Effects Notebook for Hazardous Air Pollutants-Draft", EPA-452/D-95-00, PB95-503579, December 1994." Please conduct a current literature search and check the appropriate current online database for the most recent quantitative information.

- Acute (short-term) exposure to ethylbenzene in humans results in **respiratory effects, such as throat irritation and chest constriction, irritation of the eyes, and neurological effects such as dizziness.**
- Chronic (long-term) exposure to ethylbenzene by inhalation in humans may result in effects on the blood. Animal studies have reported effects on the blood, liver, and kidneys from chronic inhalation exposure to ethylbenzene.
- The Reference Concentration (RfC) for ethylbenzene is 1 mg/m^3.[a] The U.S. Environmental Protection Agency (EPA) estimates that inhalation of this concentration or less, over a lifetime, would not likely result in the occurrence of chronic, noncancer effects.[b]
- The Reference Dose (RfD) for ethylbenzene is 0.1 mg/kg/d.[c] EPA estimates that consumption of this dose or less, over a lifetime, would not result in the occurrence of chronic, noncancer effects.
- No information is available on the developmental or reproductive effects of ethylbenzene in humans, while animal studies have reported developmental effects, including **birth defects in animals** exposed via inhalation.
- Limited information is available on the carcinogenic effects of ethylbenzene in humans or animals. EPA has classified ethylbenzene as a Group D, **not classifiable as to human carcinogenicity**.

---

[a] Milligrams per cubic meter is the unit of measurement for chemicals in air.

[b] The RfC is not a direct estimator of risk but rather a reference point to gauge the potential effects. Exceedance of the RfC does not imply that an adverse health effect would necessarily occur. As the amount and frequency of exposures exceeding the RfC increase, the probability of adverse health effects also increases.

[c] Milligrams per kilogram per day is one way to measure the amount of the contaminant that is consumed

in food.

Please Note: The main sources of information for this fact sheet are EPA's Integrated Risk Information System (IRIS), which contains information on inhalation chronic toxicity of ethylbenzene and the RfC, and oral chronic toxicity and the RfD, and the Agency for Toxic Substances and Disease Registry's (ATSDR's) *Toxicological Profile for Ethylbenzene*. Other secondary sources include the Hazardous Substances Data Bank (HSDB), a database of summaries of peer-reviewed literature, and the Registry of Toxic Effects of Chemical Substances (RTECS), a database of toxic effects that are not peer reviewed.

Environmental/Occupational Exposure

- Ethylbenzene has been detected in urban air at an average concentration of 0.66 ppb. The average level in suburban air is about 0.62 ppb, while the average level measured in air in the country is about 0.01 ppb. (1)
- Indoor air usually has a higher average concentration of ethylbenzene (about 1 ppb) than ambient air, due to the use of household products such as cleaning products or paints. (1)
- Occupational exposure to ethylbenzene occurs in factories that use ethylbenzene to produce other chemicals; for gas and oil workers; and for varnish workers, spray painters, and persons involved in gluing operations. (1)
- Exposure to ethylbenzene occurs from the use of consumer products, gasoline, pesticides, solvents, carpet glues, varnishes, paints, and tobacco smoke. (1)

Assessing Personal Exposure

- Laboratory tests can determine ethylbenzene by measuring the breakdown products in the urine. (1)

Health Hazard Information

Acute Effects:

- Respiratory effects, such as throat irritation and chest constriction, irritation of the eyes, and neurological effects such as dizziness, have been noted from acute (short-term) inhalation exposure to ethylbenzene in humans. (1-3)
- Animal studies have reported central nervous system (CNS) toxicity; pulmonary effects; and effects on the liver, kidney, and eyes (irritation) from acute inhalation exposure to ethylbenzene. (1)
- Tests involving acute exposure of animals, such as the LC_{50} and LD_{50} tests in rats, have shown ethylbenzene to have moderate toxicity from inhalation and oral exposure. (1,4)

***Chronic Effects (Noncancer)*:**

- Chronic (long-term) exposure to ethylbenzene by inhalation in humans may result in effects on the blood. In a 20-year study of humans occupationally exposed to ethylbenzene, no liver toxicity was noted. (1)
- Animal studies have reported effects on the blood, liver, and kidneys from chronic inhalation exposure to ethylbenzene. (1,3)

- The RfC for ethylbenzene is 1 mg/m^3 based on developmental toxicity in rats and rabbits. (5)
- EPA has low confidence in the study on which the RfC was based because higher exposure levels may have provided more information on the potential for maternal toxicity and developmental effects; low confidence in the database because, although other studies have examined a variety of other endpoints (e.g., liver and lung), by histopathology in rats and mice, there are no chronic studies and no multigeneration developmental studies; and, consequently, low confidence in the RfC. (5)
- The RfD for ethylbenzene is 0.1 mg/kg/d based on liver and kidney toxicity in rats. (5)
- EPA has low confidence in the study on which the RfD was based because rats of only one sex were tested and the experiment was not of chronic duration; low confidence in the supporting database because other oral toxicity data were not found; and, consequently, low confidence in the RfD. (5)
- EPA's Office of Air Quality Planning and Standards, for a hazard ranking under Section 112(g) of the Clean Air Act Amendments, has evaluated ethylbenzene for chronic toxicity. Ethylbenzene has been assigned an interim composite score of 9 (scores range from 1 to 100, with 100 being the most toxic). These scores are based on a combination of values assigned to the minimal lowest-observed-adverse-effect level (LOAEL) and a ranking of the severity of the toxic effects. (6)

Reproductive/Developmental Effects:

- No information is available on the developmental or reproductive effects of ethylbenzene in humans. (1)
- Animal studies have reported developmental effects, such as fetal resorptions, retardation of skeletal development, and an increased incidence of extra ribs in animals exposed to ethylbenzene via inhalation. Mild maternal toxicity has also been reported. (1,3)

Cancer Risk:

- The only available human cancer study monitored the conditions of workers exposed to ethylbenzene for 10 years, with no tumors reported. However, no firm conclusions can be made from this study because exposure information was not provided, and 10 years is insufficient for detecting long latency tumors in humans. (1)
- A study in rats reported a statistically significant increase in malignant tumors (type unspecified) from oral exposure. However, this study is limited because no data on specific tumor type were presented and only one dose was tested. (1)
- EPA has classified ethylbenzene as a Group D, not classifiable as to human carcinogenicity. (5)

Physical Properties

- Ethylbenzene is a colorless liquid that smells like gasoline. (1)
- The odor threshold for ethylbenzene is 2.3 ppm. (7)
- The chemical formula for ethylbenzene is C_8H_{10}, and the molecular weight is 106.16 g/mol. (1)
- The vapor pressure for ethylbenzene is 9.53 mm Hg at 25 C, and its octanol/water partition coefficient (Log K_{ow}) is 3.13. (1)

Uses

- Ethylbenzene is used primarily in the production of styrene. It is also used as a solvent, as a constituent of asphalt and naphtha, and in fuels. (1)

Conversion Factors:
To convert from ppm to mg/m^3: mg/m^3 = (ppm) × (molecular weight of the compound)/(24.45). For ethylbenzene: 1 ppm = 4.34 mg/m^3.

Health Data from Inhalation Exposure

Concentration (mg/m^3)	Health numbers[a]	Regulatory, advisory numbers[b]	Reference
1,000,000.0			
-- -- -- -- 100,000.0			
-- -- -- -- 10,000.0	• LC_{50} (rats) (17,360 mg/m^3)		4
-- -- -- -- 1,000.0		• NIOSH IDLH (8,680 mg/m^3)	1,2
-- -- -- -- 100.0	• NOAEL[c] (rats and rabbits) (434 mg/m^3)	• OSHA STEL, ACGIH STEL (545 mg/m^3) • OSHA PEL, ACGIH TLV (435 mg/m^3) •	5 1,2 1,2
-- -- -- -- 10.0			

-- -- -- -- 1.0	• RfC (1 mg/m^3)		5

ACGIH STEL--American Conference of Governmental and Industrial Hygienists' short-term exposure limit; 15-min time-weighted-average exposure that should not be exceeded at any time during a workday even if the 8-h time-weighted-average is within the threshold limit value.
ACGIH TLV--American Conference of Governmental and Industrial Hygienists' threshold limit value expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effects.
LC_{50} (Lethal $Concentration_{50}$)--A calculated concentration of a chemical in air to which exposure for a specific length of time is expected to cause death in 50% of a defined experimental animal population.
NIOSH IDLH--National Institute of Occupational Safety and Health immediately dangerous to life and health; NIOSH concentration representing the maximum level of a pollutant from which an individual could escape within 30 minutes without escape-impairing symptoms or irreversible health effects.
NOAEL--No-observed-adverse-effect level.
OSHA PEL--Occupational Safety and Health Administration's permissible exposure limit expressed as a time-weighted average; the concentration of a substance to which most workers can be exposed without adverse effect averaged over a normal 8-h workday or a 40-h workweek.
(continued)
OSHA STEL--Occupational Safety and Health Administration's short-term exposure limit; 15-min time-weighted-average exposure that should not be exceeded at any time during a workday even if the 8-h time-weighted-average is within the threshold limit value.
RfC--Reference concentration.

[a] Health numbers are toxicological numbers from animal testing or risk assessment values developed by EPA.
[b] Regulatory numbers are values that have been incorporated in Government regulations, while advisory numbers are nonregulatory values provided by the Government or other groups as advice.
[c] NOAEL is from the critical study used as the basis for the EPA RfC.

0051
Ethylbenzene; CASRN 100-41-4

Health assessment information on a chemical substance is included in IRIS only after a comprehensive review of chronic toxicity data by U.S. EPA health scientists from several Program Offices and the Office of Research and Development. The summaries presented in Sections I and II represent a consensus reached in the review process. Background information and explanations of the methods used to derive the values given in IRIS are provided in the Background Documents.

STATUS OF DATA FOR Ethylbenzene

File On-Line 01/31/1987

Category (section)	Status	Last Revised
Oral RfD Assessment (I.A.)	on-line	06/01/1991
Inhalation RfC Assessment (I.B.)	on-line	03/01/1991

Carcinogenicity Assessment (II.) on-line 08/01/1991

_I. CHRONIC HEALTH HAZARD ASSESSMENTS FOR NONCARCINOGENIC EFFECTS

__I.A. REFERENCE DOSE FOR CHRONIC ORAL EXPOSURE (RfD)

Substance Name -- Ethylbenzene
CASRN -- 100-41-4
Last Revised -- 06/01/1991

The oral Reference Dose (RfD) is based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. It is expressed in units of mg/kg-day. In general, the RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Please refer to the Background Document for an elaboration of these concepts. RfDs can also be derived for the noncarcinogenic health effects of substances that are also carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.A.1. ORAL RfD SUMMARY

Critical Effect	Experimental Doses*	UF	MF	RfD
Liver and kidney toxicity	NOEL: 136 mg/kg/day (converted to 97.1 mg/kg/day)	1000	1	1E-1 mg/kg/day
Rat Subchronic to Chronic Oral Bioassay Wolf et al., 1956	LOAEL: 408 mg/kg/day (converted to 291 mg/kg/day)			

---

*Conversion Factors: 5 days/7 days; thus, 136 mg/kg/day x 5 days/7 days = 97.1 mg/kg/day

I.A.2. PRINCIPAL AND SUPPORTING STUDIES (ORAL RfD)

Wolf, M.A., V.K. Rowe, D.D. McCollister, R.L. Hollingsworth and F. Oyen. 1956. Toxicological studies of certain alkylated benzenes and benzene. Arch. Ind. Health. 14: 387-398.

The chosen study is a rat 182-day oral bioassay in which ethylbenzene was given 5 days/week at doses of 13.6, 136, 408, or 680 mg/kg/day in olive oil gavage. There were 10 albino female rats/dose group and 20 controls.

The criteria considered in judging the toxic effects on the test animals were growth, mortality, appearance and behavior, hematologic findings, terminal concentration of urea nitrogen in the blood, final average organ and body weights, histopathologic findings, and bone marrow counts. The LOAEL of 408 mg/kg/day is associated with histopathologic changes in liver and kidney.

I.A.3. UNCERTAINTY AND MODIFYING FACTORS (ORAL RfD)

UF -- The uncertainty factor of 1000 reflects 10 for both intraspecies and interspecies variability to the toxicity of this chemical in lieu of specific data, and 10 for extrapolation of a subchronic effect level to its chronic equivalent.

MF --None

I.A.4. ADDITIONAL COMMENTS (ORAL RfD)

None.

I.A.5. CONFIDENCE IN THE ORAL RfD

Study -- Low
Data Base -- Low
RfD -- Low

Confidence in the chosen study is low because rats of only one sex were tested

and the experiment was not of chronic duration. Confidence in the supporting data base is low because other oral toxicity data were not found. Low confidence in the RfD follows.

___I.A.6. EPA DOCUMENTATION AND REVIEW OF THE ORAL RfD

U.S. EPA. 1980. Ambient Water Quality Criteria for Ethylbenzene. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Water Regulations and Standards, Washington, DC. EPA 440/5-80-048. NTIS PB 81-117590.

U.S. EPA. 1985. Drinking Water Criteria Document for Ethylbenzene. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Drinking Water, Washington, DC. (Public review draft)

U.S. EPA. 1985. Health Effects Assessment for Ethylbenzene. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Emergency and Remedial Response, Washington, DC. ECAO-CIN-H008.

The 1980 Ambient Water Quality Criteria Document for Ethylbenzene received extensive Agency and public review.

The 1985 Drinking Water Criteria Document for Ethylbenzene and the 1985 Health Effects Assessment for Ethylbenzene received extensive Agency review with the help of selected outside scientists.

Agency Work Group Review -- 05/20/1985

Verification Date -- 05/20/1985

___I.A.7. EPA CONTACTS (ORAL RfD)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

__I.B. REFERENCE CONCENTRATION FOR CHRONIC INHALATION EXPOSURE

(RfC)

Substance Name -- Ethylbenzene
CASRN -- 100-41-4
Last Revised -- 03/01/1991

The inhalation Reference Concentration (RfC) is analogous to the oral RfD and is likewise based on the assumption that thresholds exist for certain toxic effects such as cellular necrosis. The inhalation RfC considers toxic effects for both the respiratory system (portal-of-entry) and for effects peripheral to the respiratory system (extrarespiratory effects). It is expressed in units of mg/cu.m. In general, the RfC is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily inhalation exposure of the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. Inhalation RfCs were derived according to the Interim Methods for Development of Inhalation Reference Doses (EPA/600/8-88/066F August 1989) and subsequently, according to Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994). RfCs can also be derived for the noncarcinogenic health effects of substances that are carcinogens. Therefore, it is essential to refer to other sources of information concerning the carcinogenicity of this substance. If the U.S. EPA has evaluated this substance for potential human carcinogenicity, a summary of that evaluation will be contained in Section II of this file.

___I.B.1. INHALATION RfC SUMMARY

Critical Effect	Exposures*	UF	MF	RfC
Developmental toxicity Rat and Rabbit Developmental Inhalation Studies Andrew et al., 1981; Hardin et al., 1981	NOAEL: 434 mg/cu.m (100 ppm) NOAEL(ADJ): 434 mg/cu.m NOAEL(HEC): 434 mg/cu.m LOAEL: 4340 mg/cu.m (1000 ppm) LOAEL(ADJ): 4340 mg/cu.m LOAEL(HEC): 4340 mg/cu.m	300	1	1E+0 mg/cu.m

*Conversion Factors: MW = 106.18. Assuming 25C and 760 mmHg, NOAEL(mg/cu.m) = 100 ppm x MW/24.45 = 434 mg/cu.m. For developmental effects, this concentration is not adjusted; therefore, NOAEL(ADJ) = NOAEL. The NOAEL(HEC) was calculated for a gas:extrarespiratory effect, assuming periodicity was attained. Since b:a lambda values are unknown for the experimental animal species (a) and humans (h), a default value of 1.0 was used for this ratio. NOAEL(HEC) = NOAEL(ADJ) x (b:a lambda(a)/lambda(h)) = 434 mg/cu.m.

I.B.2. PRINCIPAL AND SUPPORTING STUDIES (INHALATION RfC)

Andrew, F.D., R.L. Buschbom, W.C. Cannon, R.A. Miller, L.F. Montgomery, D.W. Phelps, et al. 1981. Teratologic assessment of ethylbenzene and 2-ethoxyethanol. Battelle Pacific Northwest Laboratory, Richland, WA. PB 83-208074., 108.

Hardin, B.D., G.P. Bond, M.R. Sikov, F.D. Andrew, R.P. Beliles and R.W. Niemeier. 1981. Testing of selected workplace chemicals for teratogenic potential. Scand. J. Work Environ. Health. 7(suppl 4): 66-75.

Inhalation experiments were conducted with Wistar rats (n=78-107/concentration) and New Zealand white rabbits (n=29-30/concentration) exposed 6 to 7 hours/day, 7 days/week during days 1-19 and 1-24 of gestation, respectively, to nominal concentrations of 0, 100, or 1000 ppm (434 or 4342 mg/cu.m) (Andrew et al., 1981). A separate group of rats was exposed pregestationally for 3 weeks prior to mating and exposure was continued into the gestational period. Actual concentrations were within 10% of target concentrations. All pregnant animals were sacrificed 1 day prior to term (21 days for rats; 30 days for rabbits). Maternal organs (liver, lungs, kidney, heart, spleen, adrenals, ovaries, and brain) were examined histopathologically. Uteri were examined and fetuses were weighed, sexed, and measured for crown-to-rump length, and examined for external, internal and skeletal abnormalities. For statistical analyses, the litter was chosen as the experimental unit.

Ethylbenzene did not elicit embryotoxicity, fetotoxicity, or teratogenicity in rabbits at either exposure level. There were no significant incidences of major malformations, minor anomalies, or common variants in fetal rabbits from exposed groups. Maternal toxicity in the rabbits was not evident. There was no evidence of histologic damage in any of the dams' organs. The principal observation noted by the investigators was a reduced number of live rabbit kits per litter ($p<0.05$) at both exposure levels when evaluated by ANOVA and Duncan's Multiple Range Test. The number of live kits per litter in the air-exposed controls was reported as 8 (3+/-s.d.), compared with 7 (3+/-s.d.) for each exposure group. However, if one recalculates the data presented in Table 9 of Andrew et al. (1981), the number of live kits per litter for the low concentration (100 ppm) was 8 rather than 7 as presented in the paper. Since the number of live kits per litter at the high concentration was 7, this may suggest an effect at 1000 ppm, but not at 100 ppm. However, the number of implantations per litter and the number of dead or resorbed per litter were not different from controls. Prenatal mortality ranged from 5 to 8% and preimplantation loss ranged from 18 to 27%. Neither indicated a concentration-related intrauterine mortality. The results of the rabbit study are indicative of a NOAEL of 100 ppm based on a lack of developmental effects in rabbits. The NOAEL(HEC) is 434 mg/cu.m.

In rats exposed only during gestation, there were no histopathological effects in any of the maternal organs examined. There was no effect on fertility or on any of the other measures of reproductive status. The principal observation in fetuses was an increased incidence ($p<0.05$) of supernumerary and rudimentary ribs in the high exposure group and an elevated incidence of extra ribs in both the high and 100 ppm groups. Both absolute and relative liver, kidney, and spleen weights were significantly increased in

pregnant rats from the 1000 ppm group.

Groups of female rats were also exposed for 3 weeks prior to mating and exposure was continued during gestation. Like the 1000-ppm group exposed only during gestation, there was also an increased incidence of extra ribs ($p<0.05$) in the pre-gestationally exposed high exposure group. However, an increased incidence was not seen at 100 ppm in those exposed pre-gestationally, in contrast to the comparable group exposed only during gestation. There was no increase in rudimentary ribs in either of exposed groups. When extra and rudimentary ribs were grouped together, there was no significant increase in supernumerary ribs in either of the exposed groups. The apparent discrepancy in the incidence of supernumerary ribs between the pregestationally-exposed group and those exposed only during gestation may be based, in part, on the fewer numbers of litters examined in the pregestationally-exposed group. There were no effects on fertility or on any of the of the other measures of reproductive status. No fetal toxicity was noted at either exposure level. Body weights, placental weights, and sex ratios were within normal limits. Absolute and relative liver and spleen weights were significantly increased in pregant rats from the 1000 ppm group; only relative kidney weight was increased significantly. There were no histopathological effects in any of the organs examined.

Skeletal variants were seen at both 434 and 4342 mg/cu.m in the rats with the effects at 432 mg/cu.m being reduced compared with those occurring at 4342 mg/cu.m. By themselves, the effects are marginally adverse, even at 4342 mg/cu.m. However, a weight-of-evidence approach, noting a cluster of other mild effects at 4342 mg/cu.m, is used to determine that 1000 ppm is a LOAEL. The skeletal variations are considered along with evidence of slightly reduced litter size in rabbits at 4342 mg/cu.m and an increase in "% skeletal retarded fetuses" at 600 mg/cu.m (Ungvary and Tatrai, 1985). Additional support for this position is derived from the observations of somewhat elevated maternal liver, kidney, and spleen weights (Andrew et al., 1981).

___I.B.3. UNCERTAINTY AND MODIFYING FACTORS (INHALATION RfC)

UF -- The uncertainty factor of 300 reflects a factor of 10 to protect unusually sensitive individuals, 3 to adjust for interspecies conversion and 10 to adjust for the absence of multigenerational reproductive and chronic studies.

MF -- None

___I.B.4. ADDITIONAL STUDIES / COMMENTS (INHALATION RfC)

Ungvary and Tatrai (1985) exposed CFY rats (n=17-20) to levels of 600, 1200, or 2400 mg/cu.m for 24 hours/day during days 7 to 15 of gestation. CFLP

mice (n=20) were exposed to 500 mg/cu.m for 24 hours/day from gestational days 6 to 15 or for 3 days intermittently for 4 hours/day for days 6-15. It is not clear from the description if the results pertain to the continuous exposure or the intermittent exposure. New Zealand rabbits (n=3-9) were exposed for 24 hours/day to concentrations of 500 or 1000 mg/cu.m from gestational days 7 to 20. Untreated animals and those exposed to air only served as controls.

It was stated that maternal toxicity (unspecified species) was moderate and concentration-dependent; however, no data were presented to support this statement. Maternal weight gain was reported to have decreased for rabbits exposed to 1000 mg/cu.m. It was reported that rabbits exposed to 1000 mg/cu.m exhibited mild maternal toxicity manifested by reduced weight gain. However, the percent weight gain was not reported. There were no data for developmental endpoints in the 1000-ppm group because there were no live fetuses. One dam had died and three others aborted in this exposure group. Four dams had total resorptions. However, four other compounds in addition to ethyl benzene were tested at 1000 mg/cu.m and all caused spontaneous abortions at this level. Thus, the results are not clearly indicative of a treatment-related effect. This observation, coupled with the lack of any indication of abortions in rabbits in the Hardin et al. (1981) study, suggests that this effect in rabbits is not treatment-related.

Ungvary and Tatrai (1985) did observe a significant reduction in the mean female fetal weight in rabbit dams exposed 24 hours/day to 500 mg/cu.m. Andrew et al. (1981) did not observe such an effect in rabbits exposed up to 4348 mg/cu.m. These conflicting results in rabbits might be attributable to differences in study design.

Postimplantation loss (% dead or resorbed fetuses), and exposure-related skeletal retardation were significantly elevated ($p<0.05$) in rats at all exposure levels with one exception. Exposure to 600 mg/cu.m for 6 hours/day (it was not stated if this was a single exposure or the exposure duration on each day of gestation) did not result in any statistically significant fetal effects although there was increased incidence of dead/resorbed fetuses, lower weight of fetuses, and skeletal retarded fetuses. In the 24-hour/day exposure groups, malformations characterized as "anomalies of the uropoietic apparatus" and an increased incidence of extra ribs were significantly increased only at the highest exposure level. No data were presented on the anomalies of the uropoeitic apparatus. There was a significant ($p<0.05$) increase in skeletal retardation and fetal resorption in all continuous exposure groups although the concentration-response was shallow. The percent skeletal retarded fetuses, for example, at exposure concentrations of 600, 1200, and 2400 mg/cu.m was 26, 30, and 35%, respectively; the incidence in controls was 13%. These results in rats suggest a LOAEL(HEC) of 2400 mg/cu.m for extra ribs in the absence of demonstrable maternal toxicity.

In mice, an increased incidence of "anomalies of the uropoietic apparatus" was the only observation, but no data were presented. There was no discussion concerning maternal toxicity.

A 90-day subchronic inhalation study was conducted in F344/N rats (n=10/sex/group) and B6C3F1 mice (n=10/sex/group) that were exposed to 0, 100, 250, 500, 750, and 1000 ppm (0, 434, 1086, 2171, 3257, and 4343 mg/cu.m) 6 hours/day, 5 days/week (NTP, 1988; 1989; 1990). The duration-adjusted values were 0, 77.5, 194, 388, 582, and 776 mg/cu.m, respectively. The test

atmosphere concentrations monitored by gas chromatography were within a 10% range of the target concentrations. At study termination, necropsies were conducted on the lung, liver, kideny, heart, testes, and thymus with organ weight measurements. Clinical chemistry data were obtained for rats. Histopathological examinations were conducted on all animals in the high concentration groups and in controls; animals in the lower concentration groups were evaluated when lesions were observed until no observed effects were seen. Sperm morphology and vaginal cytology tests were performed. There were no mortalities, exposure-related clinical signs of toxicity, or significant adverse effects on body weight in any of the exposed rats or mice.

In rats, hematology parameters were unaffected. Of the liver enzymes evaluated, only serum alkaline phosphatase (SAP) activity was significantly reduced in a concentration-related manner (at 500 ppm and above) for both sexes with a greater sensitivity in females. The significance of this decrease is not clear since in liver damage, SAP levels usually increase. The investigators suggested the decrease may be due to reduced water and food intake. No liver histopathology was noted for any exposure group. Significant concentration-related increases in absolute liver weights occurred in males at 250 ppm and higher (12.5, 17.3, 22.0, and 23.6% at 250, 500, 750, and 1000 ppm, respectively); in females the lowest concentration at which an increase in absolute liver weight was seen was in the 500-ppm group (11.8%). The increase in the 750- and 1000-ppm groups was 11.5 and 15.8%, respectively. Relative liver weights were significantly increased in all male exposure groups except the 100-ppm group while all female exposure groups except the two lowest groups showed significant increases. Absolute kidney weight in males significantly increased only in the 500- and 750-ppm groups; relative weight was increased in the three highest exposure groups. In females, both absolute and relative kidney weights increased significantly in the three highest exposure groups. Regeneration of renal tubules in the kidneys of male rats only was seen in all groups including controls. The severity of the lesions was greatest in the rats at in the high-exposure group.

The most significant gross observation in rats was the presence of enlarged bronchial and/or mediastinal lymph nodes, but these observations were not dose-related. The incidence for minimal lung inflammation in male rats was 0/10, 3/10, 9/10, 9/10, 8/10, and 10/10 for the 0-, 100-, 250-, 500-, 750-, and 1000-ppm exposure groups, respectively. Microscopically, this enlargement was attributable to an increase in normal constituents of the lymph nodes characterized by accumulations of macrophages, lymphocytes, neutrophils, and plasma cells. It was the opinion of the NTP Pathology Working Group (PWG) that hyperplasia of the lymph nodes and lower respiratory tract was typical of an infectious agent with an associated active immune response rather than ethylbenzene exposure (NTP, 1989). This diagnosis was supported by the following observations: an uneven distribution of lesions among and within groups; foci of airway inflammation were randomly distributed throughout the lungs; considerable variability in severity within groups; and there was no consistent concentration-response relationship. No lesions were seen in the nasal cavity. The PWG described these lesions as not typical of the type of lesions which occurs with known pulmonary irritants. These lesions were not found in control animals, which were housed in separate rooms. No infectious agent was identified upon serologic examination. In the draft NTP technical report (NTP, 1990), the inflammatory lung lesions were described as probably unrelated to exposure. Antibodies to common rodent respiratory tract viruses were not detected. However, only sera from control

rats were sampled. Lesions morphologically indistinguishable from those in this study have been seen in control and treatment groups of rats from other inhalation and dosed feed studies (NTP, 1990). The PWG recommended that this effect be reevaluated in another study.

In mice, no significant exposure-related gross or histopathological observations were noted at terminal necropsy of any organs, including the lung. The only exposure-related effects were significantly elevated absolute and relative liver weight in both sexes of mice at of 750 and 1000 ppm and significantly elevated relative kidney weight of the females exposed to 1000 ppm. There were no significant histopathological changes or function test alterations in either liver or kidney of either sex.

The NTP peer review of the subchronic study took place on November 20, 1990 at Research Triangle Park. The NTP Board of Scientific Counselors' panel of experts agreed with the conclusions of the NTP report that there were no indications of toxicity due to ethyl benzene. A 2-year lifetime study in both rats and mice has been initiated and exposures have been conducted through 7 months. No serial sacrifices are planned and results are not expected prior to 1992.

Clark (1983) exposed Wistar rats (n=18/sex/group) (12-13 weeks old) to 0 and 100 ppm (0 and 434 mg/cu.m) reagent grade ethylbenzene 6 hours/day, 5 days/week for 12 weeks. The duration-adjusted values were 0 and 77.5 mg/cu.m. Clinical observations, body weight, food intake, hematology, urinalysis, organ weights, and histopathology of all major organs (including the lung and nasal cavity) were used as parameters to assess toxicity. No statistically significant effects were observed at 100 ppm. There were no differences from controls in the liver enzymes, including SAP. While slight bile duct hyperplasia was seen in 15/18 exposed males and 14/18 exposed females, hyperplasia was also common in controls (10/18 females and 8/18 males), and these observations were not statistically significant. The results of this study suggest a NOAEL of 100 ppm. The NOAEL(HEC) is 77.5 mg/cu.m. The results are in general agreement with the findings of the NTP study in F344 rats.

Wolf et al. (1956) exposed rats (n=10-25/sex/group) to 400, 600 or 1250 ppm (1737, 2606, or 5428 mg/cu.m) ethylbenzene 7 hours/day, 5 days/week for about 6 months. The duration-adjusted values were 0, 362, 542, and 1131 mg/cu.m, respectively, using the 7-hour duration. Exposure ranged from 186 to 214 days. Male rats only were also exposed to 2200 ppm (9554 mg/cu.m) for 7 hours/day, 5 days/week for about 5 months. The duration-adjusted value was 1990 mg/cu.m. Histopathology was performed on a variety of organs including the lung. Data on liver and kidney weights and histopathology were not presented; these parameters were discussed only in descriptive terms. Repeated exposure of rats, guinea pigs, and rhesus monkeys was examined.

Growth was depressed moderately in male rats at 2200 ppm. Liver and kidney weights in rats were increased slightly in all exposed groups compared with matched controls, and rats exposed to 1250 and 2200 ppm developed histopathological changes manifested as cloudy swelling of the liver and renal tubules and testicular degeneration. The date indicate a NOAEL for liver histopatholgy at 600 ppm (542 mg/cu.m). However, no incidence data was reported. Since it is not clear that these effects are adverse when taken in context with the results of the NTP study, a NOAEL or LOAEL is not identified.

Guinea pigs (5-10/sex/group) and rabbits (1-2/sex/group) were exposed to 0, 400, or 600 ppm (duration-adjusted concentrations of 0, 362, or 542 mg/cu.m, respectively) ethylbenzene 7 hours/day, 5 days/week for about 6 months. Only females were exposed to 1250 ppm (duration-adjusted value of 1131 mg/cu.m). Growth was depressed in female guinea pigs exposed to 1250 ppm. Liver weight was described as slightly increased only in the 600-ppm exposure group. The study does not clearly indicate 600 ppm as a LOAEL so the NOAEL for guinea pigs is designated at 600 ppm. The NOAEL(HEC) is 542 mg/cu.m. Other than an observation of slight degeneration of the testicular germinal epithelium in the male rabbit at 600 ppm, there were no adverse effects reported for rabbits of either sex.

One male Rhesus monkey was exposed to 600 ppm (duration-adjusted value of 542 mg/cu.m) and two females were exposed to 400 ppm (duration-adjusted value of 362 mg/cu.m). A slight degeneration of the testicular germinal epithelium and increased liver weight was observed in the male monkey. No effects were reported for the female rhesus monkeys.

The small number of rabbits and monkeys preclude identification of NOAEL and LOAEL values for these species.

Cragg et al. (1989) exposed B6C3F1 mice (n=5/sex/group) and F344 rats (n=5/sex/group) to actual concentrations of 0, 99, 382, and 782 ppm (0, 430, 1659, and 3396 mg/cu.m) 6 hours/day, 5 days/week for 4 weeks. The duration-adjusted values were 0, 77, 296, 606 mg/cu.m, respectively. In the same study, New Zealand White rabbits (n=5/sex/group) were exposed to actual concentrations of 0, 382, 782, or 1610 ppm (0, 1659, 3396, or 6992 mg/cu.m). The duration-adjusted values were 0, 296, 606 and 1249 mg/cu.m, respectively. No changes were evident in mortality, clinical chemistry parameters, urinalysis, nor were there treatment-related gross or histopathological findings. Urinalysis was not performed on rabbits and clinical chemistry parameters were not performed on mice. Liver enzymes measured included AP. Hematology was performed on all species. Histopathology was only conducted on the high concentration animals except all rabbits' testes were examined. There was no liver histopathology in any of the species.

In the 382-ppm exposure group, rats exhibited sporadic incidences of salivation and lacrimation. (These observations were not noted in the NTP subchronic study). Absolute liver weights were significantly increased in male rats; relative weight was increased at 782 ppm. In females, absolute liver weight was significantly increased at 782 ppm and relative weight at both concentrations. Male rats of the 782 ppm group had a significant ($p<0.05$) increase in platelets while females only had a significant ($p<0.05$) increase in total leukocytes.

In mice, females showed a statistically significant increase in absolute, but not relative liver weight, at 782 ppm. There were no significant liver weight changes in male mice. Both males and females exhibited an increased liver weight relative to brain weight at 782 ppm only. Rabbits showed no changes in liver weight ratios at any exposure level.

Since there were no adverse histopathological findings for the liver, a NOAEL of 782 ppm is identified for rats and mice. The NOAEL(HEC) is 606 mg/cu.m. The NOAEL for rabbits is 1610 ppm; the NOAEL(HEC) is 1249 mg/cu.m.

Elovaara et al. (1985) found concentration-related increases in drug-metabolizing enzymes of liver and kidney, with corresponding ultrastructural alterations in a subchronic inhalation study with rats. Male Wistar rats (n=5/group) were exposed to 0, 50, 300, or 600 ppm (0, 217, 1302, or 2604 mg/cu.m) ethylbenzene 6 hours/day, 5 days/week for 2, 5, 9, or 16 weeks. The duration-adjusted values were 0, 38.7, 233, and 465 mg/cu.m, respectively. The liver was the only organ examined histologically (light and electron microscopy). There were no changes in liver weight at any concentration. After 16 weeks exposure, NADPH-cytochrome reductase and UDPG-transferase were significantly elevated at 300 and 600 ppm. Aminopyrine N-demethylase and 7-ethoxycoumarin-0-deethylase (7-ECDE) were elevated at all exposure levels. The elevation in UDPG-transferase was exposure-related and may signify glucuronidation of ethylbenzene metabolites during detoxication. Electron microscopy also showed changes in hepatocyte ultrastructure [e.g., smooth endoplasmic reticulum (SER) proliferation, slight degranulation of rough endoplasmic reticulum] at all exposure levels beginning 2 to 9 weeks after exposure. Necrosis was not observed nor were there any increases in serum alanine aminotransferase. SAP was not measured. The proliferation of SER is consistent with enzyme induction. At 16 weeks, changes in ultrastructure were mainly confined to the high-exposure group. There was no effect of exposure on hepatic glutathione (GSH) content. Significant increases in relative kidney weight only were reported following 2 and 9, but not at 16 weeks of exposure to 600 ppm. Kidney 7-ECDE, and UDPG transferase activities showed statistically significant and exposure-related increases at all exposure levels.

In the absence of histologic evidence of damage, changes in absolute or relative liver weight, and no effect on serum ALT, the microsmal enzyme induction and ultrastructural changes are considered to be adaptation phenomena. The results of this study suggest a NOAEL of 600 ppm. The NOAEL(HEC) is 465 mg/cu.m for liver and kidney. The absence of liver weight changes is not consistent with the findings of the NTP (1988) subchronic study.

Angerer and Wulf (1985) evaluated 35 workers who chronically (2-24 years, average 8.2 years) sprayed varnishes containing alkyd-phenol and polyester resins dissolved in solvent mixtures consisting principally of xylene isomers and ethylbenzene. Some of the varnishes contained lead-based pigments. The air samples from personal monitors indicated average levels of 4.0 ppm for ethylbenzene. Although workers had significantly elevated lymphocytes in addition to significantly decreased erythrocyte counts and hemoglobin levels compared with controls, these effects cannot be attributed to ethylbenzene since other compounds (e.g., xylene, methylchloroform, n-butanol, toluene, C9 hydrocarbons) were detected in some of the six workplaces evaluated.

Bardodej and Cirek (1988) carried out biomonitoring of 200 ethylbenzene production workers occupationally exposed for a mean duration of 12.2 years to unspecified concentrations of ethylbenzene and benzene over a 20-year period. The workers were evaluated twice a year and ethylbenzene metabolites measured. No statistically significant differences in hematological effects (e.g., RBC, WBC, leukocyte and platelet counts) or liver function tests (e.g., aminotransferase and/or SAP and LDH activities and bilirubin tests) were observed between exposed and nonexposed workers.

I.B.5. CONFIDENCE IN THE INHALATION RfC

Study -- Low
Data Base -- Low
RfC -- Low

The developmental study by Hardin et al. (1981) was well-conducted and indicated no clearly adverse effects in any species. The study is given a low confidence rating because higher exposure levels may have provided more information on the potential for maternal toxicity and developmental effects. The data base is given a low rating since although other studies have examined a variety of other endpoints (e.g., liver and lung), by histopathology in rats and mice, there are no chronic studies and no multi-generation developmental studies. These latter studies would be useful to determine more conclusively the potential of ethylbenzene to affect development.

NTP does not consider observations of lung lesions in rats exposed in the NTP subchronic study to be treatment-related. However, no infectious agent has been detected. Therefore, there remains a possibility that ethylbenzene may play a role in producing lung lesions. It is anticipated that this issue will be clarified upon completion of the chronic study in progress.

In view of the previous considerations, the RfC is given a low confidence rating.

I.B.6. EPA DOCUMENTATION AND REVIEW OF THE INHALATION RfC

Source Document -- This assessment is not presented in any existing U.S. EPA document.

Other EPA Documentation -- U.S. EPA, 1984; 1985; 1987

Agency Work Group Review -- 09/19/1990, 12/20/1990

Verification Date -- 12/20/1990

I.B.7. EPA CONTACTS (INHALATION RfC)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX) or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

_II. CARCINOGENICITY ASSESSMENT FOR LIFETIME EXPOSURE

Substance Name -- Ethylbenzene
CASRN -- 100-41-4
Last Revised -- 08/01/1991

Section II provides information on three aspects of the carcinogenic assessment for the substance in question; the weight-of-evidence judgment of the likelihood that the substance is a human carcinogen, and quantitative estimates of risk from oral exposure and from inhalation exposure. The quantitative risk estimates are presented in three ways. The slope factor is the result of application of a low-dose extrapolation procedure and is presented as the risk per (mg/kg)/day. The unit risk is the quantitative estimate in terms of either risk per ug/L drinking water or risk per ug/cu.m air breathed. The third form in which risk is presented is a drinking water or air concentration providing cancer risks of 1 in 10,000, 1 in 100,000 or 1 in 1,000,000. The rationale and methods used to develop the carcinogenicity information in IRIS are described in The Risk Assessment Guidelines of 1986 (EPA/600/8-87/045) and in the IRIS Background Document. IRIS summaries developed since the publication of EPA's more recent Proposed Guidelines for Carcinogen Risk Assessment also utilize those Guidelines where indicated (Federal Register 61(79):17960-18011, April 23, 1996). Users are referred to Section I of this IRIS file for information on long-term toxic effects other than carcinogenicity.

__II.A. EVIDENCE FOR CLASSIFICATION AS TO HUMAN CARCINOGENICITY

___II.A.1. WEIGHT-OF-EVIDENCE CLASSIFICATION

Classification -- D; not classifiable as to human carcinogenicity.

Basis -- nonclassifiable due to lack of animal bioassays and human studies.

___II.A.2. HUMAN CARCINOGENICITY DATA

None.

II.A.3. ANIMAL CARCINOGENICITY DATA

None. NTP has plans to initiate bioassay. Metabolism and excretion studies at 3.5, 35 and 350 mg/kg are to be conducted as well.

II.A.4. SUPPORTING DATA FOR CARCINOGENICITY

The metabolic pathways for humans and rodents are different (Engstrom et al., 1984). Major metabolites in humans, mandelic acid and phenylglyoxylic acid, are minor metabolites in rats and rabbits (Kiese and Lenk, 1974). The major animal metabolites were not detected in the urine of exposed workers (Engstrom et al., 1984).

Ethylbenzene at 0.4 mg/plate was not mutagenic for Salmonella strains TA98, TA1535, TA1537 and TA1538 with or without Aroclor 1254 induced rat liver homogenates (S9) (Nestmann et al., 1980). Ethylbenzene was shown to increase the mean number of sister chromatid exchanges in human whole blood lymphocyte culture at the highest dose examined without any metabolic activation system (Norppa and Vainio, 1983).

Dean et al. (1985) used a battery of short-term tests including bacterial mutation assays, mitotic gene conversion in Saccharomyces cerevisiae JD1 in the presence and absence of S9 and chromosomal damage in a cultured rat liver cell line. Ethylbenzene was not mutagenic in the range of concentrations tested (0.2, 2, 20, 50 and 200 ug/plate) for S. typhimurium TA98, TA100, TA1535, TA1537 and TA1538 or for Escherichia coli WP2 and WP2uvrA. Ethylbenzene also showed no response in the S. cerevisiae JD1 gene conversion assay. In contrast, ethylbenzene hydroperoxide showed positive responses with E. coli WP2 at 200 ug/plate in the presence of S9 and an equally significant response with the gene conversion system of yeast.

II.B. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM ORAL EXPOSURE

Not available.

__II.C. QUANTITATIVE ESTIMATE OF CARCINOGENIC RISK FROM INHALATION EXPOSURE

Not available.

__II.D. EPA DOCUMENTATION, REVIEW, AND CONTACTS (CARCINOGENICITY ASSESSMENT)

___II.D.1. EPA DOCUMENTATION

Source Document -- U.S. EPA, 1980, 1984, 1987

The Ambient Water Quality Criteria Document and the Health Assessment Document have received Agency and external review. The Drinking Water Criteria Document has been extensively reviewed.

___II.D.2. REVIEW (CARCINOGENICITY ASSESSMENT)

Agency Work Group Review -- 10/07/1987

Verification Date -- 10/07/1987

___II.D.3. U.S. EPA CONTACTS (CARCINOGENICITY ASSESSMENT)

Please contact the Risk Information Hotline for all questions concerning this assessment or IRIS, in general, at (513)569-7254 (phone), (513)569-7159 (FAX)

or RIH.IRIS@EPAMAIL.EPA.GOV (internet address).

_VII. REVISION HISTORY

Substance Name -- Ethylbenzene
CASRN -- 100-41-4

Date	Section	Description
03/01/1988	I.A.1.	Dose conversion clarified
03/01/1988	I.A.6.	Documentation revised
03/01/1988	III.A.	Health Advisory added
09/07/1988	II.	Carcinogen summary on-line
08/01/1989	VI.	Bibliography on-line
08/01/1990	IV.F.1.	EPA contact changed
10/01/1990	I.B.	Inhalation RfC now under review
03/01/1991	I.B.	Inhalation RfC summary on-line
03/01/1991	VI.B.	Inhalation RfC references added
06/01/1991	I.A.7.	Primary contact changed
08/01/1991	II.D.3.	Secondary contact changed
01/01/1992	I.A.7.	Secondary contact changed
01/01/1992	IV.	Regulatory actions updated
04/01/1997	III.,IV., V.	Drinking Water Health Advisories, EPA Regulatory Actions, and Supplementary Data were removed from IRIS on or before April 1997. IRIS users were directed to the appropriate EPA Program Offices for this information.

Drinking Water and Health

As part of the Drinking Water and Health pages, this fact sheet is part of a larger publication:

National Primary Drinking Water Regulations

Consumer Factsheet on: ETHYLBENZENE

This is a factsheet about a chemical that may be found in some public or private drinking water supplies. It may cause health problems if found in amounts greater than the health standard set by the United States Environmental Protection Agency (EPA).

What is Ethylbenzene and how is it used?

Ethylbenzene is a colorless organic liquid with a sweet, gasoline-like odor. The greatest use - over 99 percent - of ethylbenzene is to make styrene, another organic liquid used as a building block for many plastics. It is also used as a solvent for coatings, and in making rubber and plastic wrap.

The list of trade names given below may help you find out whether you are using this chemical at home or work.

Trade Names and Synonyms:

Ethylbenzol
Phenylethane

Why is Ethylbenzene being Regulated?

In 1974, Congress passed the Safe Drinking Water Act. This law requires EPA to determine safe levels of chemicals in drinking water which do or may cause health problems. These non-enforceable levels, based solely on possible health risks and exposure, are called Maximum Contaminant Level Goals.

The MCLG for ethylbenzene has been set at 0.7 parts per million (ppm) because EPA believes this level of protection would not cause any of the potential health problems described below.

Based on this MCLG, EPA has set an enforceable standard called a Maximum Contaminant Level (MCL). MCLs are set as close to the MCLGs as possible, considering the ability of public water systems to detect and remove contaminants using suitable treatment technologies.

The MCL has also been set at 0.7 ppm because EPA believes, given present technology and resources, this is the lowest level to which water systems can reasonably be required to remove this contaminant should it occur in drinking water.

These drinking water standards and the regulations for ensuring these standards are met, are called National Primary Drinking Water Regulations. All public water supplies must abide by these regulations.

What are the Health Effects?

Short-term: EPA has found ethylbenzene to potentially cause the following health effects when people are exposed to it at levels above the MCL for relatively short periods of time: drowsiness, fatigue, headache and mild eye and respiratory irritation.

Long-term: Ethylbenzene has the potential to cause the following effects from a lifetime exposure at levels above the MCL: damage to the liver, kidneys, central nervous system and eyes.

How much Ethylbenzene is produced and released to the environment?

Production of ethylbenzene has increased: from 6.9 billion lbs. in 1982 to 11.8 billion lbs in 1993. It is released to the air primarily from its use in gasoline. More localized may be due to waste water and spills from its production and industrial use.

From 1987 to 1993, according to EPA's Toxic Chemical Release Inventory, ethylbenzene releases to water and land totalled over 761,000 lbs. These releases were primarily from petroleum refining industries. The largest releases occurred in Texas. The largest direct releases to water occurred in Virginia.

What happens to Ethylbenzene when it is released to the environment?

Ethylbenzene will evaporate rapidly from water, and will be degraded by microbes. It binds only moderately to aquatic sediment and to soils. Thus, it may leach to ground water if released to land. Ethylbenzene has little potential for accumulating in aquatic life.

How will Ethylbenzene be Detected in and Removed from My Drinking Water?

The regulation for ethylbenzene became effective in 1992. Between 1993 and 1995, EPA required your water supplier to collect water samples every 3 months for one year and analyze them to find out if ethylbenzene is present above 0.5 ppb. If it is present above this level, the system must continue to monitor this contaminant.

If contaminant levels are found to be consistently above the MCL, your water supplier must take steps to reduce the amount of ethylbenzene so that it is consistently below that level. The following treatment methods have been approved by EPA for removing ethylbenzene: Granular activated charcoal in combination with Packed Tower Aeration.

How will I know if Ethylbenzene is in my drinking water?

If the levels of ethylbenzene exceed the MCL, 0.7 ppm, the system must notify the public via newspapers, radio, TV and other means. Additional actions, such as providing alternative drinking water supplies, may be required to prevent serious risks to public health.

Drinking Water Standards:

Mclg: 0.7 ppm

Mcl: 0.7 ppm

Ethylbenzene Releases to Water and Land, 1987 to 1993 (in pounds):

	Water	Land
TOTALS (in pounds)	**47,293**	**714,580**
Top Ten States		
TX	9,870	480,164
VI	1,233	72,245
IL	31	44,789
PR	0	23,980
VA	17,997	1,950
DE	3,460	13,324
NJ	1,892	11,510
NM	0	13,076
WY	250	12,755
LA	4,383	4,552
Major Industries		
Petroleum refining	55,201	718,884
Plastics, resins	12,384	9,212
Indust. Organics	10,683	9,781
Pharmaceuticals	14,090	0
Metal containers	0	11,510

* Water/Land totals only include facilities with releases greater than a certain amount - usually 1000 to 10,000 lbs.

Learn more about your drinking water!

EPA strongly encourages people to learn more about their drinking water, and to support local efforts to protect and upgrade the supply of safe drinking water. Your water bill or telephone books government listings are a good starting point.

Your local water supplier can give you a list of the chemicals they test for in your water, as well as how your water is treated.

Your state Department of Health/Environment is also a valuable source of information.

For help in locating these agencies or for information on drinking water in general, call: EPAs Safe Drinking Water Hotline: (800) 426-4791.

For additional information on the uses and releases of chemicals in your state, contact the: Community Right-to-Know Hotline: (800) 535-0202.

International Chemical Safety Cards

ETHYLBENZENE

ICSC: 0268

ETHYLBENZENE
Ethylbenzol
Phenylethane
EB
$C_8H_{10}/C_6H_5-C_2H_5$
Molecular mass: 106.2

CAS # 100-41-4
RTECS # DA0700000
ICSC # 0268
UN # 1175
EC # 601-023-00-4

TYPES OF HAZARD/ EXPOSURE	ACUTE HAZARDS/ SYMPTOMS	PREVENTION	FIRST AID/ FIRE FIGHTING
FIRE	Highly flammable.	NO open flames, NO sparks, and NO smoking.	Powder, AFFF, foam, carbon dioxide.
EXPLOSION	Vapour/air mixtures are explosive.	Closed system, ventilation, explosion-proof electrical equipment and lighting. Do NOT use compressed air for filling, discharging, or handling.	In case of fire: keep drums, etc., cool by spraying with water.
EXPOSURE		PREVENT GENERATION OF MISTS!	
• **INHALATION**	Cough. Dizziness. Drowsiness. Headache.	Ventilation, local exhaust, or breathing protection.	Fresh air, rest. Refer for medical attention.
• **SKIN**	Dry skin. Redness.	Protective gloves.	Remove contaminated clothes. Rinse and then wash skin with water and soap.
• **EYES**	Redness. Pain. Blurred vision.	Face shield or eye protection in combination with breathing protection.	First rinse with plenty of water for several minutes (remove contact lenses if easily possible), then take to a doctor.

• **INGESTION**	(further see Inhalation).	Do not eat, drink, or smoke during work.	Rinse mouth. Give a slurry of activated charcoal in water to drink. Refer for medical attention.

SPILLAGE DISPOSAL	STORAGE	PACKAGING & LABELLING
Ventilation. Collect leaking liquid in covered containers. Absorb remaining liquid in sand or inert absorbent and remove to safe place. Do NOT wash away into sewer (extra personal protection: A filter respirator for organic vapour).	Fireproof. Separated from strong oxidants. ICSC: 0268

Prepared in the context of cooperation between the International Programme on Chemical Safety & the Commission of the European Communities © IPCS CEC 1993 No modifications to the International version have been made except to add the OSHA PELs, NIOSH RELs and IDLH values.

International Chemical Safety Cards

ETHYLBENZENE

ICSC: 0268

IMPORTANT DATA

PHYSICAL STATE; APPEARANCE:
COLOURLESS LIQUID , WITH AROMATIC ODOUR.

PHYSICAL DANGERS:
The vapour mixes well with air, explosive mixtures are easily formed.

CHEMICAL DANGERS:
Reacts with strong oxidants. Attacks plastic and rubber.

OCCUPATIONAL EXPOSURE LIMITS (OELs):
TLV (as TWA): 100 ppm; 434 mg/m^3; as STEL: 125 ppm; 543 mg/m^3 (ACGIH 1994-1995).
MAK: 100 ppm; 440 mg/m^3 (1994).
OSHA PEL: TWA 100 ppm (435 mg/m^3)
NIOSH REL: TWA 100 ppm (435 mg/m^3) ST 125 ppm (545 mg/m^3)
NIOSH IDLH: 800 ppm LEL

ROUTES OF EXPOSURE:
The substance can be absorbed into the body by inhalation of its vapour, through the skin and by ingestion.

INHALATION RISK:
A harmful contamination of the air will be reached rather slowly on evaporation of this substance at 20°C.

EFFECTS OF SHORT-TERM EXPOSURE:
The substance irritates the eyes, the skin and the respiratory tract. Swallowing the liquid may cause aspiration into the lungs with the risk of chemical pneumonitis. The substance may cause effects on the central nervous system. Exposure far above OEL could cause lowering of consciousness.

EFFECTS OF LONG-TERM OR REPEATED EXPOSURE:
Repeated or prolonged contact with skin may cause dermatitis.

PHYSICAL PROPERTIES	Boiling point: 136°C Melting point: -95°C Relative density (water = 1): 0.9 Solubility in water, g/100 ml at 20°C: 0.015 Vapour pressure, kPa at 20°C: 0.9 Relative vapour density (air = 1): 3.7 Relative density of the vapour/air-mixture at 20°C (air = 1): 1.02 Flash point: 18°C c.c. Auto-ignition temperature: 432°C Explosive limits, vol% in air: 1.0-6.7 Octanol/water partition coefficient as log Pow: 3.2
ENVIRONMENTAL DATA	The substance is harmful to aquatic organisms. 

N O T E S

The odour warning when the exposure limit value is exceeded is insufficient.

Transport Emergency Card: TEC (R)-522
NFPA Code: H2; F3; R0

ADDITIONAL INFORMATION

ETHYLBENZENE

-IDENTIFIERS
 ===========

*CATALOG ID NUMBER: 000486

*CAS NUMBER: 100-41-4

*BASE CHEMICAL NAME: ETHYLBENZENE

*PRIMARY NAME: ETHYLBENZENE

*CHEMICAL FORMULA: C8H10

*STRUCTURAL FORMULA:

*WLN: 2R

*SYNONYMS:
  EB
  ETHYLBENZOL
  PHENYLETHANE
  NCI C56393

-PHYSICAL CHEMICAL DATA
 ======================

*PHYSICAL DESCRIPTIONS: LITERATURE: Clear, colorless liquid
                         REPOSITORY: Clear, colorless liquid

*MOLECULAR WEIGHT: 106.16

*SPECIFIC GRAVITY: 0.867 @ 20/4 C

*DENSITY: 0.866 g/cm3 @ 21 C (RAD)

*MP (DEG C): -95 C

*BP (DEG C): 136.2 C

*SOLUBILITIES:
       WATER : <1 mg/mL @ 23 C (RAD)

        DMSO : >=100 mg/mL @ 23 C (RAD)

 95% ETHANOL : 1-10 mg/mL @ 23 C (RAD)

    METHANOL : Not available

     ACETONE : >=100 mg/mL @ 23 C (RAD)

     TOLUENE : Not available

 OTHER SOLVENTS:
  Most organic solvents: Soluble
  Carbon tetrachloride: Soluble
  Sulfur dioxide: Soluble

Ammonia: Insoluble
ETHER : Soluble
BENZENE: Soluble

*VOLATILITY:
Vapor pressure: 10 mm Hg @ 29.5 C; 5 mm Hg @ 13.9 C; 760 mm Hg @ 136.2 C
Vapor density : 3.66

*FLAMMABILITY(FLASH POINT):
The flash point for this chemical is 15 C (59 F). It is flammable. Fires involving this compound can be controlled with a dry chemical, carbon dioxide or Halon extinguisher. The autoignition temperature is 432 C (810 F).

*UEL: 6.8% LEL: 1.2%

*REACTIVITY:
This compound can react vigorously with strong oxidizing materials.

*STABILITY:
This chemical is stable under normal laboratory conditions. Solutions of this chemical should be stable for 24 hours under normal lab conditions (RAD).

*OTHER PHYSICAL DATA:
Aromatic odor
Refractive index: 1.49594 @ 20 C; 1.4932 @ 25 C
Specific heat: 0.41 cal/gal/degrees C
Viscosity: 0.64 centipoise @ 25 C
Specific gravity: 0.866 @ 25/25 C
Boiling point: 25.8 C @ 10 mm Hg

-TOXICITY
========

*NIOSH REGISTRY NUMBER: DA0700000

*TOXICITY:

typ. dose	mode	specie	amount	unit	other
TCLo	ihl	hmn	100	ppm/8H	
LD50	orl	rat	3500	mg/kg	
LCLo	ihl	rat	4000	ppm/4H	
LD50	skn	rbt	17800	mg/kg	
LCLo	ihl	gpg	10000	ppm	

*AQTX/TLM96: 100-10 ppm.

*SAX TOXICITY EVALUATION:
THR: MODERATE via irritation to the skin, eyes and mucous membranes, and via oral and inhalation routes. A concentration of 0.19% vapor in air will irritate eyes; 0.2% is extremely irritating. An experimental teratogen.

*CARCINOGENICITY:
Status: NTP Carcinogenesis Studies; selected but deferred, April 1984

*MUTATION DATA:

-OTHER DATA (Regulatory)
 ======================

*PROPER SHIPPING NAME (IATA): Ethylbenzene

*UN/ID NUMBER: UN1175

*HAZARD CLASS: 3             SUBSIDIARY RISK: None    PACKING GROUP: II

*LABELS REQUIRED: Flammable liquid

*PACKAGING: PASSENGER: PKG. INSTR.: 305, Y305       MAXIMUM QUANTITY: 5 L, 1 L
            CARGO    : PKG. INSTR.: 307             MAXIMUM QUANTITY: 60 L

*SPECIAL PROVISIONS: None

*USES:
  Intermediate in production of styrene; organic synthesis; solvent; dilutant;
  antiknock agent; acetophenone manufacture; asphalt constituent; naphtha con-
  stituent.

-HANDLING PROCEDURES
 ====================
```

*ACUTE/CHRONIC HAZARDS:
This compound can cause irritation of the skin, eyes and mucous membranes. It is toxic by ingestion, inhalation and skin absorption. In high concentrations it may be narcotic. It may also cause lachrimation.

*MINIMUM PROTECTIVE CLOTHING: Not available

*RECOMMENDED GLOVE MATERIALS: P
The following gloves show the best resistance based on permeation testing. It is recommended that two different glove types be used for best protection. However, if this chemical makes direct contact with your glove, or if a tear, puncture or hole develops, remove them at once.

SUGGESTED GLOVES (RAD): Viton

*RECOMMENDED RESPIRATOR:
Where the neat test chemical is weighed and diluted, wear a NIOSH-approved half face respirator equipped with an organic vapor/acid gas cartridge (specific for organic vapors, HCl, acid gas and SO2) with a dust/mist filter.

*OTHER: Not available

*STORAGE PRECAUTIONS:
You should store this chemical under refrigerated temperatures, and keep it away from oxidizing materials. STORE AWAY FROM SOURCES OF IGNITION.

*SPILLS AND LEAKAGE:
If you should spill this chemical, FIRST REMOVE ALL SOURCES OF IGNITION, then use absorbent paper to pick up all liquid spill material. Your contaminated clothing and absorbent paper should be sealed in a vapor-tight plastic bag for eventual disposal. Solvent wash all contaminated surfaces with acetone followed by washing with a soap and water solution. Do not reenter the contaminated area until the Safety Officer (or other responsible person) has verified that the area has been properly cleaned.

*DISPOSAL AND WASTE TREATMENT:
Not available

-EMERGENCY PROCEDURES
==========

*SKIN CONTACT:
IMMEDIATELY flood affected skin with water while removing and isolating all contaminated clothing. Gently wash all affected skin areas thoroughly with soap and water.
If symptoms such as redness or irritation develop, IMMEDIATELY call a physician and be prepared to transport the victim to a hospital for treatment.

*INHALATION:
IMMEDIATELY leave the contaminated area; take deep breaths of fresh air. If symptoms (such as wheezing, coughing, shortness of breath, or burning in the mouth, throat, or chest) develop, call a physician and be prepared to transport the victim to a hospital.
Provide proper respiratory protection to rescuers entering an unknown atmosphere. Whenever possible, Self-Contained Breathing Apparatus (SCBA) should be used; if not available, use a level of protection greater than or equal to that advised under Respirator Recommendation.

*EYE CONTACT:
First check the victim for contact lenses and remove if present. Flush victim's eyes with water or normal saline solution for 20 to 30 minutes while simultaneously calling a hospital or poison control center.
Do not put any ointments, oils, or medication in the victim's eyes without specific instructions from a physician.
IMMEDIATELY transport the victim after flushing eyes to a hospital even if no symptoms (such as redness or irritation) develop.

*INGESTION:
DO NOT INDUCE VOMITING. If the victim is conscious and not convulsing, give 1 or 2 glasses of water to dilute the chemical and IMMEDIATELY call a hospital or poison control center. Be prepared to transport the victim to a hospital if advised by a physician.
If the victim is convulsing or unconscious, do not give anything by mouth, ensure that the victim's airway is open and lay the victim on his/her side with the head lower than the body. DO NOT INDUCE VOMITING. IMMEDIATELY transport the victim to a hospital.

*SYMPTOMS:
Symptoms of exposure to this compound may include irritation, redness and inflammation of the skin; irritation of the nose, throat, and eyes; lachrimation, conjunctivitis, corneal erosion, dermatitis, dizziness, narcosis and a sensation of constriction of the chest.

*FIREFIGHTING:

HAZARDOUS SUBSTANCE FACT SHEET

Common Name: **ETHYL BENZENE**

CAS Number: 100-41-4
DOT Number: UN 1175

RTK Substance number: 0851
Date: March 1989 Revision: February 1996

HAZARD SUMMARY

* **Ethyl Benzene** can affect you when breathed in and by passing through your skin.
* **Ethyl Benzene** may cause mutations. Handle with extreme caution.
* **Ethyl Benzene** can irritate the eyes, nose and throat.
* Contact with **Ethyl Benzene** can irritate the skin. Prolonged exposure can cause drying, scaling and even blistering.
* Exposure to high concentrations can cause you to become dizzy, lightheaded, and to pass out. Very high levels can cause trouble breathing and even death.
* High exposure may damage the liver.
* **Ethyl Benzene** is a FLAMMABLE LIQUID and a FIRE HAZARD.

IDENTIFICATION

Ethyl Benzene is a colorless liquid with an aromatic odor. It is used in the production of *styrene* and synthetic polymers, as a solvent and as a component of automotive and aviation fuels.

REASON FOR CITATION

* **Ethyl Benzene** is on the Hazardous Substance List because it is regulated by OSHA and cited by ACGIH, DOT, DEP, NIOSH, NFPA, HHAG and EPA.
* This chemical is on the Special Health Hazard Substance List because it is **FLAMMABLE**.
* Definitions are provided on page 5.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

The New Jersey Right to Know Act requires most employers to label chemicals in the workplace and requires public employers to provide their employees with information and training concerning chemical hazards and controls. The federal OSHA Hazard Communication Standard, 1910.1200, requires private employers to provide similar training and information to their employees.

* Exposure to hazardous substances should be routinely evaluated. This may include collecting air samples. Under OSHA 1910.20, you have a legal right to obtain copies of sampling results from your employer. If you think you are experiencing any work-related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.
* **ODOR THRESHOLD = 0.092-0.60 ppm**.
* The range of accepted odor threshold values is quite broad. Caution should be used in relying on odor alone as a warning of potentially hazardous exposures.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is **100 ppm** averaged over an 8-hour workshift.

NIOSH: The recommended airborne exposure limit is **100 ppm** averaged over a 10-hour workshift.

ACGIH: The recommended airborne exposure limit is **100 ppm** averaged over an 8-hour workshift and **125 ppm** as a STEL (short term exposure limit).

* **Ethyl Benzene** may cause mutations. All contact with this chemical should be reduced to the lowest possible level.
* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* Wear protective work clothing.
* Wash thoroughly immediately after exposure to **Ethyl Benzene** and at the end of the workshift.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of **Ethyl Benzene** to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short-term) health effects may occur immediately or shortly after exposure to **Ethyl Benzene**:

* **Ethyl Benzene** can irritate the eyes, nose and throat.
* Contact with **Ethyl Benzene** can irritate the skin.
* Exposure to high concentrations can cause you to become dizzy, lightheaded and to pass out. Very high levels can cause trouble breathing and even death.

Chronic Health Effects

The following chronic (long-term) health effects can occur at some time after exposure to **Ethyl Benzene** and can last for months or years:

Cancer Hazard

* **Ethyl Benzene** may cause mutations (genetic changes). Whether or not it poses a cancer or reproductive hazard needs further study.

Reproductive Hazard

* There is limited evidence that **Ethyl Benzene** may damage the developing fetus.

Other Long-Term Effects

* Prolonged exposure can cause drying, scaling and even blistering of the skin
* High exposure may damage the liver.
* This chemical has not been adequately evaluated to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum-based chemicals have been shown to cause such damage. Effects may include reduced memory and concentration, personality changes (withdrawal, irritability), fatigue, sleep disturbances, reduced coordination, and/or effects on nerves supplying internal organs (autonomic nerves) and/or nerves to the arms and legs (weakness, "pins and needles").

MEDICAL

Medical Testing

If symptoms develop or overexposure is suspected, the following may be useful:

* Liver function tests.

Evaluate for brain effects such as changes in memory, concentration, sleeping patterns and mood (especially irritability and social withdrawal), as well as headaches and fatigue. Consider evaluations of the cerebellar, autonomic and peripheral nervous systems. Positive and borderline individuals should be referred for neuropsychological testing.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

Request copies of your medical testing. You have a legal right to this information under OSHA 1910.20.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, **ENGINEERING CONTROLS** are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the controls mentioned above, but is sometimes necessary.

In evaluating the controls present in your workplace, consider: (1) how hazardous the substance is, (2) how much of the substance is released into the workplace and (3) whether harmful skin or eye contact could occur. Special controls should be in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically pump liquid **Ethyl Benzene** from drums or other storage containers to process containers.
* Before entering a confined space where **Ethyl Benzene** may be present, check to make sure that an explosive concentration does not exist.

Good **WORK PRACTICES** can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by **Ethyl Benzene** should change into clean clothing promptly.
* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to **Ethyl Benzene**.
* Eye wash fountains should be provided in the immediate work area for emergency use.
* If there is the possibility of skin exposure, emergency shower facilities should be provided.

* On skin contact with **Ethyl Benzene**, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted **Ethyl Benzene**, whether or not known skin contact has occurred.
* Do not eat, smoke, or drink where **Ethyl Benzene** is handled, processed, or stored, since the chemical can be swallowed. Wash hands carefully before eating or smoking.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT. However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with **Ethyl Benzene**. Wear solvent-resistant gloves and clothing. Safety equipment suppliers/ manufacturers can provide recommendations on the most protective glove/clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.

Eye Protection

* Wear splash-proof chemical goggles and face shield when working with liquid, unless full facepiece respiratory protection is worn.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* Where the potential exists for exposures over **100 ppm**, use a MSHA/NIOSH approved respirator with an organic vapor cartridge/canister. More protection is provided by a full facepiece respirator than by a half-mask respirator, and even greater protection is provided by a powered-air purifying respirator.
* If while wearing a filter, cartridge or canister respirator, you can smell, taste, or otherwise detect **Ethyl Benzene**, or in the case of a full facepiece respirator you experience eye irritation, leave the area immediately. Check to make sure the respirator-to-face seal is still good. If it is, replace the filter, cartridge, or canister. If the seal is no longer good, you may need a new respirator.
* Be sure to consider all potential exposures in your workplace. You may need a combination of filters, prefilters, cartridges, or canisters to protect against different forms of a chemical (such as vapor and mist) or against a mixture of chemicals.
* Where the potential for high exposures exists, use a MSHA/NIOSH approved supplied-air respirator with a full facepiece operated in the positive pressure mode or with a full facepiece, hood, or helmet in the continuous flow mode, or use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in pressure-demand or other positive pressure mode.
* Exposure to **800 ppm** is immediately dangerous to life and health. If the possibility of exposures above **800 ppm** exists, use a MSHA/NIOSH approved self-contained breathing apparatus with a full facepiece operated in continuous flow or other positive pressure mode.

QUESTIONS AND ANSWERS

Q: If I have acute health effects, will I later get chronic health effects?

A: Not always. Most chronic (long-term) effects result from repeated exposures to a chemical.

Q: Can I get long-term effects without ever having short-term effects?

A: Yes, because long-term effects can occur from repeated exposures to a chemical at levels not high enough to make you immediately sick.

Q: What are my chances of getting sick when I have been exposed to chemicals?

A: The likelihood of becoming sick from chemicals is increased as the amount of exposure increases. This is determined by the length of time and the amount of material to which someone is exposed.

Q: When are higher exposures more likely?
A: Conditions which increase risk of exposure include physical and mechanical processes (heating, pouring, spraying, spills and evaporation from large surface areas such as open containers), and "confined space" exposures (working inside vats, reactors, boilers, small rooms, etc.).

Q: Is the risk of getting sick higher for workers than for community residents?
A: Yes. Exposures in the community, except possibly in cases of fires or spills, are usually much lower than those found in the workplace. However, people in the community may be exposed to contaminated water as well as to chemicals in the air over long periods. Because of this, and because of exposure of children or people who are already ill, community exposures may cause health problems.

Q: Who is at the greatest risk from reproductive hazards?
A: Pregnant women are at greatest risk from chemicals that harm the developing fetus. However, chemicals may affect the ability to have children, so both men and women of childbearing age are at high risk.

Q: Can men as well as women be affected by chemicals that cause reproductive system damage?
A: Yes. Some chemicals reduce potency or fertility in both men and women. Some damage sperm and eggs, possibly leading to birth defects.

The following information is available from:

New Jersey Department of Health and
Senior Services
Occupational Disease and Injury Services
Trenton, NJ 08625-0360
(609) 984-1863

Industrial Hygiene Information

Industrial hygienists are available to answer your questions regarding the control of chemical exposures using exhaust ventilation, special work practices, good housekeeping, good hygiene practices, and personal protective equipment including respirators. In addition, they can help to interpret the results of industrial hygiene survey data.

Medical Evaluation

If you think you are becoming sick because of exposure to chemicals at your workplace, you may call a Department of Health and Senior Services physician who can help you find the services you need.

Public Presentations

Presentations and educational programs on occupational health or the Right to Know Act can be organized for labor unions, trade associations and other groups.

Right to Know Information Resources

The Right to Know Infoline (609) 984-2202 can answer questions about the identity and potential health effects of chemicals, list of educational materials in occupational health, references used to prepare the Fact Sheets, preparation of the Right to Know survey, education and training programs, labeling requirements, and general information regarding the Right to Know Act. Violations of the law should be reported to (609) 984-2202.

DEFINITIONS

ACGIH is the American Conference of Governmental Industrial Hygienists. It recommends upper limits (called TLVs) for exposure to workplace chemicals.

A **carcinogen** is a substance that causes cancer.

The **CAS number** is assigned by the Chemical Abstracts Service to identify a specific chemical.

A **combustible** substance is a solid, liquid or gas that will burn.

A **corrosive** substance is a gas, liquid or solid that causes irreversible damage to human tissue or containers.

DEP is the New Jersey Department of Environmental Protection.

DOT is the Department of Transportation, the federal agency that regulates the transportation of chemicals.

EPA is the Environmental Protection Agency, the federal agency responsible for regulating environmental hazards.

A **fetus** is an unborn human or animal.

A **flammable** substance is a solid, liquid, vapor or gas that will ignite easily and burn rapidly.

The **flash point** is the temperature at which a liquid or solid gives off vapor that can form a flammable mixture with air.

HHAG is the Human Health Assessment Group of the federal EPA.

IARC is the International Agency for Research on Cancer, a scientific group that classifies chemicals according to their cancer-causing potential.

A **miscible** substance is a liquid or gas that will evenly dissolve in another.

mg/m^3 means milligrams of a chemical in a cubic meter of air. It is a measure of concentration (weight/volume).

MSHA is the Mine Safety and Health Administration, the federal agency that regulates mining. It also evaluates and approves respirators.

A **mutagen** is a substance that causes mutations. A **mutation** is a change in the genetic material in a body cell. Mutations can lead to birth defects, miscarriages, or cancer.

NAERG is the North American Emergency Response Guidebook. It was jointly developed by Transport Canada, the United States Department of Transportation and the Secretariat of Communications and Transportation of Mexico. It is a guide for first responders to quickly identify the specific or generic hazards of material involved in a transportation incident, and to protect themselves and the general public during the initial response phase of the incident.

NCI is the National Cancer Institute, a federal agency that determines the cancer-causing potential of chemicals.

NFPA is the National Fire Protection Association. It classifies substances according to their fire and explosion hazard.

NIOSH is the National Institute for Occupational Safety and Health. It tests equipment, evaluates and approves respirators, conducts studies of workplace hazards, and proposes standards to OSHA.

NTP is the National Toxicology Program which tests chemicals and reviews evidence for cancer.

OSHA is the Occupational Safety and Health Administration, which adopts and enforces health and safety standards.

PEOSHA is the Public Employees Occupational Safety and Health Act, a state law which sets PELs for New Jersey public employees.

ppm means parts of a substance per million parts of air. It is a measure of concentration by volume in air.

A **reactive** substance is a solid, liquid or gas that releases energy under certain conditions.

A **teratogen** is a substance that causes birth defects by damaging the fetus.

TLV is the Threshold Limit Value, the workplace exposure limit recommended by ACGIH.

The **vapor pressure** is a measure of how readily a liquid or a solid mixes with air at its surface. A higher vapor pressure indicates a higher concentration of the substance in air and therefore increases the likelihood of breathing it in.

Common Name: **ETHYL BENZENE**
DOT Number: **UN 1175**
NAERG Code: **129**
CAS Number: **100-41-4**

Hazard rating	NJDHSS	NFPA
FLAMMABILITY	-	3
REACTIVITY	-	0
POISONOUS GASES ARE PRODUCED IN FIRE CONTAINERS MAY EXPLODE IN FIRE		

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* **Ethyl Benzene** is a FLAMMABLE LIQUID.
* Use dry chemical, CO_2, water spray, or alcohol resistant foam extinguishers.
* POISONOUS GASES ARE PRODUCED IN FIRE.
* CONTAINERS MAY EXPLODE IN FIRE.
* Vapors may travel to a source of ignition and flash back.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If **Ethyl Benzene** is spilled or leaked, take the following steps:

* Restrict persons not wearing protective equipment from area of spill or leak until clean-up is complete.
* Remove all ignition sources.
* Ventilate area of spill or leak.
* It may be necessary to contain and dispose of **Ethyl Benzene** as a HAZARDOUS WASTE. Contact your Department of Environmental Protection (DEP) or your regional office of the federal Environmental Protection Agency (EPA) for specific recommendations.
* If employees are required to clean-up spills, they must be properly trained and equipped. OSHA 1910.120(q) may be applicable.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department. You can request emergency information from the following:

CHEMTREC: (800) 424-9300
NJDEP HOTLINE: (609) 292-7172

==========

HANDLING AND STORAGE

* Prior to working with **Ethyl Benzene** you should be trained on its proper handling and storage.
* **Ethyl Benzene** must be stored to avoid contact with STRONG OXIDIZERS since violent reactions occur.
* Sources of ignition, such as smoking and open flames, are prohibited where **Ethyl Benzene** is handled, used, or stored.
* Metal containers involving the transfer of **Ethyl Benzene** should be grounded and bonded. Drums must be equipped with self-closing valves, pressure vacuum bungs, and flame arresters.
* Use only non-sparking tools and equipment, especially when opening and closing containers of **Ethyl Benzene**.

FIRST AID

IN NJ, POISON INFORMATION 1-800-962-1253

Eye Contact
* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids.

Skin Contact
* Quickly remove contaminated clothing. Immediately wash contaminated skin with large amounts of soap and water.

Breathing
* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

Web Sites

that offer searchable chemical databases, recommended by Scorecard

---

If you want more detailed information about a chemical than Scorecard provides, there are several on-line and library resources Scorecard recommends for further research.

ON-LINE CHEMICAL DATABASES

CambridgeSoft Chemfinder
http://chemfinder.camsoft.com/

Search

Chemfinder gives basic physico-chemical data and molecular structures for chemicals, and provides links to international data sources addressing specific chemicals.

Hazardous Substances Data Bank
http://toxnet.nlm.nih.gov/

Search

HSDB focuses on the toxicology of potentially hazardous chemicals, and includes peer-reviewed information on human exposure, industrial hygiene, emergency handling procedures, environmental fate, and regulatory requirements.

University of Akron Hazardous Chemicals Database
http://ull.chemistry.uakron.edu/erd/

Search

The Hazardous Chemicals Database provides physical data on chemicals and links to Department of Transportation safety guides that are valuable for emergency response.

BIBLIOGRAPHIC RESOURCES ON CHEMICAL TOXICITY

Scorecard provides qualitative summaries of the health hazards posed by a chemical (e.g., it is a suspected neurotoxicant), but not direct access to supporting toxicological data. These scientific studies are abstracted in several toxicity databases, which are available in libraries, from commercial vendors, and sometimes on-line. The major toxicity databases include:

The Registry of Toxic Effects of Chemicals Substances (RTECS)
RTECS is a database of toxicological information compiled by the National Institute for Occupational Safety and Health. It contains summary information about the types of health effects chemicals can cause and the concentrations at which toxicity is known to occur. It is available from several commercial vendors at http://www.cdc.gov/niosh/rtecs.html, and can often be found at major public or university libraries.

TOXLINE
Free access to the National Library of Medicine's toxicology-specific database of abstracts, reference journal articles, and reports is available at http://www.medscape.com/misc/FormToxlineInfLive.html

MEDLINE

Free access to the National Library of Medicine's MEDLINE database of more than 9 million references to articles published in 3800 biomedical journals is available at http://www.nlm.nih.gov/databases/freemedl.html. Two Web-based products, PubMed and Internet Grateful Med, provide this access. Medline can also be accessed at http://www.medscape.com/misc/FormMedlineInfLive.html

SOLVENT NAPHTHA (PETROLEUM), LIGHT ALIPHATIC (64742-89-8)

summary from the About the Chemicals section of Scorecard

- **Human Health Hazards** **Reference(s)**

  Recognized: --

  Suspected: --

- **Hazard Rankings**

  Data lacking; not ranked by any system in Scorecard.

- **Chemical Use Profile**

  This is a high volume chemical with production exceeding 1 million pounds annually in the U.S.

  No data on industrial use in Scorecard.

  Used in consumer products, building materials or furnishings that contribute to indoor air pollution.

- **Profile of Environmental Release and Waste Generation**

  No data on environmental releases in Scorecard.

- **Regulatory Coverage**

  Not on chemical lists in Scorecard.

- **Basic Testing to Identify Chemical Hazards**

  6 of 8 basic tests to identify chemical hazards have not been conducted on this chemical, or are not publicly available.

- **Information Needed for Safety Assessment**

  Lacks at least some of the national data required for safety assessment.

  No data on risk assessment values in Scorecard.

- **Links**

  Other web sites specific to this chemical:

  If none of these sources meet your needs, you can try searching some other chemical database Web sites.

Basic Testing to Identify Chemical Hazards

for SOLVENT NAPHTHA (PETROLEUM), LIGHT ALIPHATIC (64742-89-8) from Scorecard

---

The U.S. EPA conducted a comprehensive review of publicly available chemical testing data in 1997 to examine whether the basic information needed to identify chemical hazards is available for high production volume chemicals. EPA searched major chemical databases to determine if the following tests had been conducted on a chemical:

- Acute toxicity
- Chronic toxicity
- Neurotoxicity
- Developmental or reproductive toxicity
- Mutagenicity
- Carcinogenicity
- Ecotoxicity
- Environmental fate

The following basic tests to identify chemical hazards have either not been conducted or are not publicly available:

- Carcinogenicity
- Chronic toxicity
- Developmental or reproductive toxicity
- Ecotoxicity
- Environmental fate
- Neurotoxicity

More on the importance of basic toxicity testing

Metabolism/Metabolites :

The purpose of this study was to clarify whether the blood concentration of inhaled toluene, ethylbenzene, m-xylene, or mesitylene can change after the concomitant pulmonary absorption of **ethyl acetate. (**Adult female Sprague-Dawley rats were exposed in a 20 liter glass chamber under dynamic conditions for 2 hours to various concentrations of the aromatics without or in combination with different concentrations of **ethyl acetate (**0, 1000, or 4000 ppm) in air. Concentration ranges were as follows: toluene, 140-690 ppm; ethylbenzene, 120-650 ppm; m-xylene, 100-560 ppm; mesitylene, 120-720 ppm; and **ethyl acetate,** 1000 or 4000 ppm. The coexposures with **ethyl acetate** lowered the blood concentrations of other inhaled aromatics. This reduction was statistically significant following a 2 hour exposure to 230 ppm toluene in combination with 1000 ppm **ethyl acetate,** 650 ppm ethylbenzene with 1000 ppm **ethyl acetate,** and 100 ppm m-xylene with 4000 ppm **ethyl acetate.)** Similarly a significant reduction of the blood level of the aromatics by **ethyl acetate** coinhalation was also observed at higher exposure concentrations with toluene and m-xylene. A metabolic interaction such as enhanced disposition of the aromatics, may be responsible for these effects. However, it is possible that the solubility of the solvents could be altered by the presence of **ethyl acetate.** It was concluded that coexposures to concentrations in the order of the threshold limit values (100 ppm for these solvents) with 400 ppm **ethyl acetate** should not be followed by a dangerous change of the blood levels of the aromatics.
[Freundt KJ et al; Bull Environ Contam Toxicol 42 (4): 495-8 (1989)]**PEER REVIEWED**

Welcome to TOXNET - A cluster of databases on toxicology, hazardous chemicals, and related areas. TOXNET NEWS. New: TRI98 now available!

For **Toxicology Data** (Factual information on toxicity and other hazards of chemicals)	
HSDB	Hazardous Substances Data Bank - Broad scope in human and animal toxicity, safety and handling, environmental fate, and more. Scientifically peer-reviewed.
IRIS	Integrated Risk Information System - data from the Environmental Protection Agency (EPA) in support of human health risk assessment, focusing on hazard identification and dose-response assessment.
CCRIS	Chemical Carcinogenesis Research Information System - carcinogenicity, mutagenicity, tumor promotion, and tumor inhibition data provided by the National Cancer Institute (NCI).
GENE-TOX	GENE-TOX - Peer-reviewed mutagenicity test data from the EPA.

For **Toxicology Literature** (Scientific studies, reports, and other bibliographic material)	
TOXLINE	Extensive array of references to literature on biochemical, pharmacological, physiological, and toxicological effects of drugs and other chemicals.
EMIC	Environmental Mutagen Information Center - Current and older literature on agents tested for genotoxic activity.
DART/ETIC	Developmental and Reproductive Toxicology and Environmental Teratology Information Center - Current and older literature on developmental and reproductive toxicology.

For **Toxic Release Information** (Annual estimated releases of toxic chemicals to the environment - the Environmental Protection Agency's TRI (Toxics Release Inventory)	
TRI	Toxics Release Inventory - reporting years 1995 - 1998.

For **Chemical Information** (Nomenclature, Identification, Structures)	
ChemID*plus*	Numerous chemical synonyms, structures, regulatory list information, and links to other databases containing information about the chemicals.
HSDB Structures	2D structural information on the HSDB chemicals.
NCI-3D	2D and 3D information compiled by the National Cancer Institute, and augmented by MDL.

TOXNET is sponsored by the National Library of Medicine, through the Toxicology and Environmental Health Information Program of its Specialized Information Services Division.

Human Health Effects:

Human Toxicity Excerpts:

STUDY OF 30 WORKERS EXPOSED CHRONICALLY TO 15-50 MG OF **ETHYL ACETATE** IN ADDITION TO 20 TO 80 MG OF AMYL ACETATE/L OF AIR SHOWED NO ... ABNORMALITIES IN CORNEA, MERELY HYPEREMIA OF BULBAR CONJUNCTIVA. ... PROLONGED INHALATION MAY BE DAMAGING TO LUNG, LIVER, KIDNEY, & HEART. ... NO EFFECT ON EYES ... KNOWN FROM SYSTEMIC ABSORPTION.

[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 412]**PEER REVIEWED**

UNACCLIMATED SUBJECTS ... FOUND THE ODOR /OF **ETHYL ACETATE/** OBJECTIONABLY STRONG AT 200 PPM, AND MILD EYE, NOSE, AND THROAT IRRITATION AT 400 PPM.

[American Conference of Governmental Industrial Hygienists. Documentation of the Threshold Limit Values and Biological Exposure Indices. 5th ed. Cincinnati, OH:American Conference of Governmental Industrial Hygienists, 1986. 239]**PEER REVIEWED**

ETHYL ACETATE TESTED AT 10% IN PETROLATUM PRODUCED NO IRRITATION AFTER A 48-HOUR CLOSED PATCH TEST IN 25 HUMAN SUBJECTS. SENSITIZATION: A MAXIMIZATION TEST WAS CARRIED OUT ON 25 VOLUNTEERS. THE MATERIAL WAS TESTED AT A CONCN OF 10% IN PETROLATUM AND PRODUCED NO SENSITIZATION REACTIONS.

[Opdyke, D.L.J. (ed.). Monographs on Fragrance Raw Materials. New York: Pergamon Press, 1979. 341]**PEER REVIEWED**

SYMPTOMATOLOGY (acute intoxication): 1. Early emotional lability: exhilaration, boastfulness, talkativeness, remorse, and belligerency. 2. Impaired motor coordination: slowed reaction time, slurred speech, ataxia. 3. Sensory disturbances: diplopia, vertigo. 4. Flushing of face, rapid pulse, sweating. 5. Nausea and vomiting. Eventual incontinence of urine and feces. 6. Drowsiness, stupor, and finally coma, with impaired or absent tendon reflexes. Convulsive episodes may indicate hypoglycemia. 7. Pupils dilated or normal. 8. Peripheral vascular collapse (shock); hypotension, tachycardia, cold pale skin, hypothermia. 9. Slow stentorous respiration. 10. Death from respiratory or circulatory failure or from aspiration pneumonitis. 11. During convalescence: postalcoholic headache and gastritis; infections, alcoholic psychoses. /Ethyl alcohol/

[Gosselin, R.E., R.P. Smith, H.C. Hodge. Clinical Toxicology of Commercial Products. 5th ed. Baltimore: Williams and Wilkins, 1984.,p. III-169-70]**PEER REVIEWED**

Poison by inhalation. Moderately toxic by intraperitoneal and subcutaneous routes. Mildly toxic by ingestion. Human systemic effects by inhalation: olfactory changes, conjunctiva irritation, and

pulmonary changes. Human eye irritant. Irritating to mucous surfaces ... and is also mildly narcotic. On repeated or prolonged exposures, it causes conjunctival irritation and corneal clouding. High concentrations have a narcotic effect and can cause congestion of the liver and kidneys. Chronic poisoning has been described as producing anemia, leucocytosis (transient increase in the white blood cell count), and cloudy swelling, and fatty degeneration of the viscera.
[Lewis, R.J. Sax's Dangerous Properties of Industrial Materials. 9th ed. Volumes 1-3. New York, NY: Van Nostrand Reinhold, 1996. 1514]**PEER REVIEWED**

ETHYL ACETATE HAS ... REPUTATION OF BEING ONE OF THE LEAST TOXIC OF THE VOLATILE ORGANIC SOLVENTS.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 569]**PEER REVIEWED**

IRRITANT EFFECT OF **ETHYL ACETATE** IS LESS STRONG THAN THAT OF PROPYL ACETATE OR BUTYL ACETATE.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Volumes I and II. New York: McGraw-Hill Book Co., 1971. 477]**PEER REVIEWED**

... ALLEGED ILL EFFECTS OF **ETHYL ACETATE** HAVE OCCURRED DURING ITS INTENSIVE USE DURING EARLIER YEARS ... IMPURITIES MAY HAVE BEEN PRESENT OR IT MAY HAVE BEEN USED WITHOUT DUE CARE AND OFTEN IN COMBINATION WITH OTHER SOLVENTS.
[Snyder, R. (ed.). Ethel Browning's Toxicity and Metabolism of Industrial Solvents. Second Edition. Volume 3 Alcohols and Esters. New York, NY: Elsevier, 1992. 239]**PEER REVIEWED**

THE ALIPHATIC ESTERS USED AS LACQUER SOLVENTS, PRIMARILY **ETHYL ACETATE** AND BUTYL ACETATE, HAVE ... /SRP: CNS DEPRESSANT/ PROPERTIES WHICH ARE LESS PROMINENT THAN THOSE ASSOCIATED WITH THE CHLORINATED HYDROCARBONS.
[Hamilton, A., and H. L. Hardy. Industrial Toxicology. 3rd ed. Acton, Mass.: Publishing Sciences Group, Inc., 1974. 313]**PEER REVIEWED**

/Seventeen/ track team runners were evaluated after complaining of wheezing coughing, rhinitis, or shortness of breath after practicing in a facility under construction. Investigation revealed levels of **ethyl acetate** and toluene low enough to meet federal guidelines but apparently sufficient to cause symptoms in the athletes. Therefore, current standards for regulating potentially toxic organic chemicals may be inadequate when aerobic exercise is performed in the polluted environment.
[Larson DC; Physician Sportsmed 13 (1): 76-79 (1985)]**PEER REVIEWED**

A survey of the uptake of 5-hydroxytryptamine (serotonin) in platelets of workers exposed to organic solvents was conducted. Blood samples were obtained from six males, ages 34 to 58, employed in a graphic paint manufacturing facility and from 50 nonexposed individuals, 25 to 56 years old. Platelets were isolated and incubated with (14)carbon labeled serotonin. The uptake of radiolabeled serotonin, serum concentrations of calcium, potassium, and sodium ions, platelet count, and blood pH were also

determined. Breathing zone concentrations of organic solvents were obtained and analyzed by gas chromatography. The platelet count of the exposed workers was less than that of the comparisons. Maximal uptake rates of serotonin by platelets from the exposed workers was significantly greater than that of the comparisons. No significant differences in blood ion concentrations or pH values in the workers or comparisons were noted. The total concentration of organic solvents in the breathing zones of the exposed subjects ranged from 13 to 111 ppm. Compounds identified were 2 to 68 ppm toluene and 34 to 78 ppm **ethyl acetate. /**It was/ concluded that platelets of workers are affected by exposure to paint solvents.
[Beving H; Scand J Work Environ Health 10 (4): 229-34 (1984)]**PEER REVIEWED**

Ethyl acetate vapor is irritating to the eyes and respiratory passages of man at concentrations above 400 ppm. ... Due to its irritating properties, employees will not voluntarily remain in such high concentrations. ... This substance is a defatting agent, and prolonged exposure may cause irritation of the skin. Painful conjunctival irritation may occur from splashes in the eye. No chronic systemic effects have been reported in humans.
[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981. 1]**PEER REVIEWED**

Overexposure to **ethyl acetate** may cause irritation of the eyes, nose, & throat. Severe overexposure may cause weakness, drowsiness, & unconsciousness.
[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981.]**PEER REVIEWED**

Humans exposed to a concn of 400 ppm in 1.4 mg/l **ethyl acetate** for a short time were effected by nose and throat irritation. /From table/
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 2981]**PEER REVIEWED**

... **Ethyl acetate** is an irritant of the conjuctiva and mucous membrane of the respiratory tract. Animal experiments have shown that, at very high concentrations, the ester has /CNS depressant/ and lethal effects; at concentrations of 20000 to 43000 ppm, there may be pulmonary edema with hemorrhages, symptoms of central nervous system depression, secondary anemia and damage of the liver. In man, concentrations of 400 ppm cause irritation of the nose and pharynx; cases have also been known of irritation of the conjunctiva with temporary opacity of the cornea. In rare cases exposure may cause sensitization of the mucous membrane and eruptions of the skin. The irritant effect of **ethyl acetate** is less strong than that of propyl acetate or butyl acetate.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 782]**PEER REVIEWED**

Skin, Eye and Respiratory Irritations:

Irritating to mucous surfaces, particularly the eyes, gums and respiratory passages ... . On repeated or prolonged exposures, it causes conjunctival irritation and corneal clouding.
[Lewis, R.J. Sax's Dangerous Properties of Industrial Materials. 9th ed. Volumes 1-3. New York, NY: Van Nostrand Reinhold, 1996. 1514]**PEER REVIEWED**

Medical Surveillance:

Consider the points of attack /eyes, skin, respiratory system/ in placement and periodic examinations.
[Sittig, M. Handbook of Toxic and Hazardous Chemicals and Carcinogens, 1985. 2nd ed. Park Ridge, NJ: Noyes Data Corporation, 1985. 408]**PEER REVIEWED**

Whole Blood: Reference Ranges: Normal - Not established; Exposed - Not established; Toxic - Not stablished.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1256]**PEER REVIEWED**

Serum or Plasma: Reference Ranges: Normal - Not established; Exposed - Not established; Toxic - Not stablished.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1256]**PEER REVIEWED**

Urine: Reference Ranges: Normal - Not established; Exposed - Not established; Toxic - Not stablished.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1256]**PEER REVIEWED**

Respiratory Symptom Questionnaires: Questionnaires have been published by the American Thoracic Society and the British Medical Research Council. These questionnaires have been found to be useful in identification of people with chronic bronchitis, however certain pulmonary function tests such as FEV 1 have been found to be better predictors of chronic airflow obstruction.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Chest Radiography: This test is widely used for assessing pulmonary disease. Chest radiographs have been found to be useful for detection of early lung cancer in asymptomatic people, especially for detection of peripheral tumors such as adenocarcinomas. However, even though OSHA mandates this test for exposure to some toxicants such as asbestos, there are conflicting views on its efficacy in detection of pulmonary disease.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Pulmonary Function Tests: The tests that have been found to be practical for population monitoring include: Spirometry and expiratory flow-volume curves; Determination of lung volumes; Diffusing

capacity for carbon monoxide; Single-breath nitrogen washout; Inhalation challenge tests; Serial measurements of peak expiratory flow; Exercise testing.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Sputum Cytology: Sputum cytology along with chest radiographs have been the standard procedures for detecting early lung cancer in asymptomatic patients. Sputum cytology has been found to be useful for detection of central tumors, especially squamous carcinomas. For this test to be effective, exfoliated respiratory mucosal cells must be present in the expectorated specimen. Pooling of sputum collected over 2-3 days may enhance the sensitivity of this test by increasing the yield of exfoliated cells in the specimen.

Evaluation of Peripheral Neuropathy: Nerve conduction study; Electromyography; Quantitative sensory testing; Thermography.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Evaluation of Central Nervous System Effects: Evaluation of CNS effects can be performed through neuropsychological assessment, which consists of a clinical interview and administration of standardized personality and neuropsychological tests. The areas that the neuropsychology test batteries focus on include the domains of memory and attention; visuoperceptual, visual scanning, visuospatial, and visual memory; and motor speed and reaction time. There is limited data on which components of the test batteries are best indicators of early CNS effects.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Evaluation of Cranial Neuropathies: Evaluation of cranial nerve damage, as evidenced by symptoms such as loss of balance, visual function, smell, taste, or sensation on the face, can be accomplished through a physical examination focusing on tests such as: Smell assessment - standardized odor threshold and identification testing; Vision assessment - standard acuity tests, visual field tests, contrast sensitivity, and color vision measurements (vision assessment); Facial and Trigeminal Nerve assessment - blink reflex (pontogram); Vestibular assessment - pure tone audiometry for bone- and air-conducted sounds, threshold decay at 4 kHz, speech discrimination and speech reception thresholds, tympanograms and acoustic thresholds, electronystagmograms; Hearing assessment - audiometry testing.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Populations at Special Risk:

Employees /with chronic respiratory, skin, liver, or kidney disase may be/ at increased risk from **ethyl acetate.**

[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981. 1]**PEER REVIEWED**

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 375,906 workers (87,691 of these are female) are potentially exposed to **ethyl acetate** in the US(1). Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used(SRC). **Ethyl acetate** was identified (relative abundance) in air samples collected where printing pastes (66%) and paints (30%) were used, in car repair shops (45%), and in various other industries (57%) in Belgium(2). Mean concentrations of **ethyl acetate** in air during parquet work in Finland were 119 ppm during installation with resin adhesives; 319 ppm during puttying; 72 ppm during sanding after puttying; 413 ppm during undercoat varnishing (nitrocellulose); 64 ppm during urea-formaldehyde varnishing; and 1 ppm during work with water-based varnishes(3). It was also detected in air during the use of contact adhesives at mean concentrations of 14 ppm during repair of a textile carpet (dispersion and contact adhesives); 83 ppm during repair of a textile carpet (contact adhesives only); 29 ppm during beading of textile carpets (contact adhesives only); and 71 ppm during repair of bathroom floor mats (dispersion and contact adhesives)(3). **Ethyl acetate** was detected in 36% of all air samples, at a mean concentration of 11 ppm, collected from Finnish furniture factories from 1975 to 1984(4). Breathing zone samples collected during spray painting contained **ethyl acetate** at a geometric mean concentration of 9.51 ppm(5). It was detected in the air of one auto paint shop at a concentration of 10.5 mg/cu m(6). **Ethyl acetate** was identified in 12% of 275 products (including thinners, degreasers, paints, inks, and dome reagents) used in workplaces in various industries(7). **Ethyl acetate** was identified in the breathing zone of shoe factory workers(8). **Ethyl acetate** was detected in the ambient air of shoe factory in Italy in Nov 1991 at median concentrations of 10 and 7 mg/cu m(9). [(1) NIOSH; National Occupational Exposure Survey (NOES) (1983) (2) Veulemans H et al; Am Indust Hyg Assoc J 48: 671-7 (1987) (3) Riala REE, Riihimaki HA; Appl Occup Environ Hyg 6: 301-8 (1991) (4) Priha E; Ann Occup Hyg 30: 289-94 (1986) (5) Myer HE et al; Am Ind Hyg Assoc J 54: 663-70 (1993) (6) Medinilla J, Espigares M; Ann Occup Hyg 32: 509-13 (1988) (7) Lehman E et al; pp. 31-41 in Safety and Health ASP Org Sol Expos Finland April 1985, Riihimaki V, Ulfvarson U, eds NY,NY: Alan R Liss Inc (1986) (8) Ahonen I, Schimberg RW; Br J Ind Med 45: 133-6 (1988) (9) Mutti A et al; Int Arch Occup Environ Health 65: S171-6 (1993)]**PEER REVIEWED**

The general population may be exposed to **ethyl acetate** via inhalation of ambient air, ingestion of food and drinking water, and dermal contact with consumer products containing **ethyl acetate. (**SRC) **PEER REVIEWED**

Body Burden:

Mother's milk from 4 urban areas in the USA, 1 of 8 samples positive(1). 7 out of 12 breath samples collected from nine volunteers in Bayonne and Elizabeth, NJ between July and Dec 1980 contained **ethyl acetate** at unreported concentrations(2). **Ethyl acetate** was identified as a component in 13.7% of

expired air samples from 54 volunteers in the Chicago area at a geometric mean concentration of 0.447 ng/l(3). **Ethyl acetate** was detected in expired air samples from 5 of 8 male volunteers at levels ranging from 0.30 to 190.0 ug/hr(4).

The following Overview, *** **ETHYL ACETATE ***,** is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Ethyl acetate** is low in toxicity. It is a mild mucous membrane irritant, but is not caustic. In high concentrations it may be a CNS depressant. Animal studies have demonstrated pulmonary edema, decreased cardiac contractility, seizures and hepatic damage, but these have NOT been reported in humans.

0.2.1.2 CHRONIC EXPOSURE

- Chronic poisoning has been described as producing anemia, leucocytosis (transient increase in the white blood cell count) and cloudy swelling, and fatty degeneration of the viscera in animal studies (Sax & Lewis, 1989).

HEENT

0.2.4.1 ACUTE EXPOSURE

- **Ethyl acetate** is irritating to the conjunctivae but leaves no residual effects. Nose and throat irritation is seen at levels greater than 400 ppm for 3 to 5

minutes.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Chronic exposure to solvent mixtures including **ethyl acetate** has been associated with poorer performance on neurobehavioral tests. High concentrations orally administered to rabbits caused lack of coordination. High concentrations have intoxicating properties in animals and would be expected to cause narcosis in humans.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Drying as well as skin defatting and cracking may be seen with dermal application. Sensitizations to **ethyl acetate** have been reported but are rare.

Laboratory:

- Various techniques are available, primarily using gas chromatography or spectrometric techniques. Toxic levels have not been established.

Treatment Overview:

SUMMARY EXPOSURE

- Because of rapid hydrolysis and low toxicity, inhalation or ingestion of ethyl acetates seldom requires treatment. Patients should be monitored for CNS depression if large amounts have been ingested.

ORAL EXPOSURE

- Emesis or activated charcoal is unlikely to be necessary due to the low toxicity of these compounds.
- No specific antidotes or treatments are available. Monitor patients ingesting large amounts for CNS depression, respiratory depression, and decreased cardiac contractility.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or

photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- No adverse symptoms were noted in workers exposed to 375 to 1,500 ppm for several months. Humans find concentrations greater than 200 ppm objectionable because of the strong odor. 400 ppm caused nose and throat irritation. The TLV is 400 ppm (1,400 mg/m(3)).

Antidote and Emergency Treatment:

For basic treatment: Establish a patent airway. Suction if necessary. Watch for signs of respiratory insufficiency and assist ventilations if necessary. Administer oxygen by nonrebreather mask at 10 to 15 L/min. Monitor for pulmonary edema and treat if necessary ... . Monitor for shock and treat if necessary ... . For eye contamination, flush eyes immediately with water. Irrigate each eye continuously with normal saline during transport ... . Do not use emetics. For ingestion, administer activated charcoal ... . /Esters and related compounds/

[Bronstein, A.C., P.L. Currance; Emergency Care for Hazardous Materials Exposure. 2nd ed. St. Louis, MO. Mosby Lifeline. 1994. 221]**PEER REVIEWED**

For advanced treatment: Consider orotracheal or nasotracheal intubation for airway control in the patient who is unconscious. Positive-pressure ventilation techniques with a bag-valve-mask device may be beneficial. Monitor cardiac rhythm and treat arrhythmias if necessary ... . Start an IV with D5W TKO /SRP: To keep open, "minimal flow rate"/. Ringer's if signs of hypovolemia are present. Watch for signs of fluid overload. For hypotension with signs of hypovolemia, administer fluid cautiously. Consider vasopressors if patient is hypotensive with a normal fluid volume. Watch for signs of fluid overload ... . Consider drug therapy for pulmonary edema ... . Use proparacaine hydrochloride to assist eye irrigation ... . /Esters and related compounds/

REVIEWED**

In order to determine the lung disease potential of waterproofing sprays, several components of suspected sprays, as well as a commercial spray, were tested on CD-l-mice. Mice placed in inhalation chambers were exposed to aerosols containing one or more of the suspected components, including N-heptane, **ethyl-acetate,** fluororesin, silicone, and a commercial spray. An intermittent inhalation methods was used to prevent the solvents from causing anesthetic death. Mice were sacrificed 1 hour after the end of exposure. The lungs of both exposed and control mice were isolated and examined microscopically for any changes. The amounts released of the were similar. Mice exposed to the commercial and fluororesin sprays were cyanotic and depressed for 1 hour, while those exposed to the other sprays were cyanotic for only several minutes. In almost all mice exposed to the commercial spray, significant changes relative to the controls included a thickened pulmonary alveolar septa, cellular infiltration, fused and hemorrhaged alveolar walls, and diminished alveoli. Fluororesin particles were found in the alveolar space. Significantly more pronounced pathological changes were discovered in mice exposed to the fluororesin spray, relative to the commercial spray. In mice exposed to the silicone spray, significant differences were observed in alveolar collapse and hemorrhage, compared to the controls. The lungs of mice exposed to the N-heptane, **ethyl-acetate,** and fluororesin free sprays were similar to control lungs. In mice exposed to the silicon resin free spray, significant changes, relative to the commercial spray group, included alveolar collapse, hyperemia, hemorrhage and increased thickness and cellular infiltration of the septum. /It was/ concluded that **ethyl-acetate** and N-heptane contained in waterproofing sprays do not cause pulmonary disorders. Instead, fluororesin is implicated in respiratory disorders caused by such sprays.
[Yamashita M, Tanaka J; J Toxicol, Clin Toxicol 33 (6): 631-7 (1995)]**PEER REVIEWED**

The neurotoxic effects of inhaled amyl-acetate, **ethyl-acetate,** and n-butyl-acetate were investigated in mice. Male CFW-albino-mice were exposed to up to 40,000 ppm amyl-acetate, 2,000 ppm **ethyl-acetate,** or 8,000 ppm n-butyl-acetate for 20 minutes in an exposure chamber. Acute neurotoxic effects were assessed by measuring locomotor activity and functional observational battery. Similar acute behavioral effects on locomotor activity were observed in mice following **ethyl-acetate** and n-butyl-acetate exposure, with amyl-acetate inducing little neurotoxic effect. Exposure to the compounds caused changes in posture, with decreased arousal and rearing; increased central nervous system excitability, as manifested by increased tonic and clonic movements; and increased autonomic effects. Also, decreased mobility and righting reflex, and an elevated reaction to sensory stimuli were observed. Handling induced convulsions were produced in some mice following acute exposure; potency differences were observed. Significant decreases in locomotor activity were seen with exposure to **ethyl-acetate** and n-butyl-acetate at the highest concentrations tested, and minimally effective levels for activity decreasing effects were 2,000 and 8,000 ppm for **ethyl-acetate** and n-butyl-acetate, respectively. Rapid recovery was seen in mice after removal from exposure. /It was/ concluded that acute exposure to acetyl-acetate, n-butyl-acetate, and **ethyl-acetate** produces acute neurobehavioral effects which differ from the effects produced by exposure to alkylbenzenes and halogenated hydrocarbon solvents.

Interactions:

ETHYL ACETATE IN COMBINATION WITH TOLUENE APPEARED TO PRODUCE A MIXTURE OF LOWER TOXICITY THAN THAT OF EITHER COMPOUND ALONE. MIXING OF **ETHYL ACETATE** WITH PROPYLENE OXIDE, PROPYLENE GLYCOL, OR FORMALIN APPEARS TO DECR ITS LD50 VALUE, BUT ITS TOXICITY INCREASES IN COMBINATION WITH MORPHOLINE, ETHYLENE GLYCOL, OR ETHYL ALCOHOL.

York, NY: John Wiley & Sons Inc., 1993-1994. 2984]**PEER REVIEWED**

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Ethyl acetate's production and use as a pharmaceutic aid, in artificial fruit essences, and as a solvent may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 93 mm Hg at 25 deg C indicates **ethyl acetate** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **ethyl acetate** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 9.4 days. If released to soil, **ethyl acetate** is expected to have high mobility based upon an estimated Koc of 59. Volatilization from moist soil surfaces is expected to occur based upon a Henry's Law constant of 1.34X10-4 atm-cu m/mole. **Ethyl acetate's** vapor pressure indicates the potential for volatilization from dry soil surfaces exists. Biodegradation is expected to be an important process in both soil and water, based upon **ethyl acetate's** biodegradation in aqueous screening studies. 93% biodegradation was observed in a complete mix continuous-flow activated sludge system. 26.6 and 57.1% of **ethyl acetate'**s theoretical BOD was reached in 5 days using the standard dilution method and seawater dilution method, respectively. If released into water, **ethyl acetate** is not expected to adsorb to suspended solids and sediment in water based on the estimated Koc. Volatilization from water surfaces is expected to be an important fate process based on **ethyl acetate's** Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 8.9 hours and 5.6 days, respectively. An estimated BCF of 3.2 suggests the potential for bioconcentration in aquatic organisms is low. **Ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years. Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used or where adhesives, thinners, degreasers, paints, inks, and dome reagents are used. The general population may be exposed to **ethyl acetate** via inhalation of ambient air, ingestion of food and drinking water, or dermal contact with consumer products containing this compound. PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 375,906 workers (87,691 of these are female) are potentially exposed to **ethyl acetate** in the US(1). Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used(SRC). **Ethyl acetate** was identified (relative abundance) in air samples collected where printing pastes (66%) and paints (30%) were used, in car repair shops (45%), and in various other industries (57%) in Belgium(2). Mean concentrations of **ethyl acetate** in air during parquet work in Finland were 119 ppm during installation with resin adhesives; 319 ppm during puttying; 72 ppm during sanding after puttying; 413 ppm during undercoat varnishing (nitrocellulose); 64 ppm during urea-formaldehyde varnishing; and 1 ppm during work with water-based varnishes(3). It was also detected in air during the use of contact adhesives at mean concentrations of 14 ppm during repair of a textile carpet (dispersion and contact adhesives); 83 ppm during repair of a textile carpet (contact adhesives only); 29 ppm during beading of textile carpets (contact adhesives only); and 71 ppm during repair of bathroom floor mats (dispersion and contact adhesives)(3). **Ethyl acetate** was detected in 36% of all air samples, at a mean concentration of 11 ppm, collected from Finnish furniture factories from 1975 to 1984(4). Breathing zone samples collected during spray painting contained **ethyl acetate** at a

geometric mean concentration of 9.51 ppm(5). It was detected in the air of one auto paint shop at a concentration of 10.5 mg/cu m(6). **Ethyl acetate** was identified in 12% of 275 products (including thinners, degreasers, paints, inks, and dome reagents) used in workplaces in various industries(7). **Ethyl acetate** was identified in the breathing zone of shoe factory workers(8). **Ethyl acetate** was detected in the ambient air of shoe factory in Italy in Nov 1991 at median concentrations of 10 and 7 mg/cu m(9).

A review concluded that **ethyl acetate** is easily removed by biological treatment(1). Reported 5 day BOD values using a sewage inoculum range from 36-68% of theoretical(2-5) with the value being somewhat reduced in salt water(2). One investigator reported that **ethyl acetate** was completely degraded in 20 hr using activated sludge(6). In a bench-scale continuous-flow activated sludge reactor with an 8 hour retention time, 99.9% removal (including 17% volatilization loss) was obtained, with 80% of the theoretical BOD(7). **Ethyl acetate** was 90% biooxidized in a 20-day BOD test using a filtered raw sewage seed; it was biooxidized 77% in a 28-day OECD closed-bottle test(8). A screening procedure that was systematically applied to a large number of organic chemicals ranked **ethyl acetate** as being completely biodegraded in a short time by general microorganisms(9). After a 5 hr lag, 43 to 53% of theoretical BOD was obtained in 50 to 70 hr(9). In screening tests, **ethyl acetate,** present at a concentration of 5 ppm, reached 26.6 and 57.1% of its theoretical BOD in 5 days using the standard dilution method and seawater dilution method, respectively(10). 99.9% removal of **ethyl acetate** was observed in a complete mix continuous-flow activated sludge system; 93% of this removal was attributed

to biodegradation(11).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **ethyl acetate** with photochemically-produced hydroxyl radicals is 1.6X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 10 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1,SRC). The observed rate constant for the vapor-phase reaction of **ethyl acetate** with nitrate radicals is 1.4X10-17 cu cm/molecule-sec(2). This corresponds to an atmospheric half-life of about 16 years at an average nighttime nitrate radical concentration of 2X10+8 molecules/cu cm (nitrate radicals are unstable in sunlight)(3,SRC). The rate constant for the reaction of **ethyl acetate** with hydroxyl radicals in aqueous solution is 4.0X10+8 L/mol sec(4). This corresponds to a half-life of about 5.5 years(SRC) at an average aqueous hydroxyl radical concentration of 1X10-17 mol/l(5). Simple esters are resistant to hydrolysis; **ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years(6).

Volatilization from Water/Soil:

The Henry's Law constant for **ethyl acetate** is 1.34X10-4 atm-cu m/mole(1). This Henry's Law constant indicates that **ethyl acetate** is expected to volatilize from water surfaces(2,SRC). Based on this Henry's Law constant, the estimated volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec) is estimated as 8.9 hours(2,SRC). The estimated volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec) is estimated as 5.6 days(2,SRC). **Ethyl acetate's** Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). The potential for volatilization of **ethyl acetate** from dry soil surfaces may exist(SRC) based on a vapor pressure of 93 mm Hg(3). 7% of the 99.9% removal observed in a continuous flow activated sludge system was attributed to stripping(4).

Food Survey Values:

Ethyl acetate forms from the reaction of acetyl coenzyme A with ethanol, and its formation depends greatly on temperature. Maximum formation occurs at 20-25 deg C. Therefore, top fermented beers contain higher amounts of this ester.
[Kirk-Othmer Encyclopedia of Chemical Technology. 3rd ed., Volumes 1-26. New York, NY: John Wiley and Sons, 1978-1984.,p. V24 789 (1984)]**PEER REVIEWED**

Ethyl acetate is found in USA lager beer, 25 to 50 ppm(1). It is a component of Orleans vinegar(2) and artificial grape flavoring(3). **Ethyl acetate** was identified as a volatile component of roasted filberts(4), fried bacon(5), Beaufort cheese(6), blue cheese(7), Idaho Russet Burbank baked potatoes(8), and the edible Korean chamchwi plant(9). Korean salt-fermented anchovy, big-eyed herring, hair tail viscera and shrimp pastes contained **ethyl acetate** at mean concentrations of 3490, 1660, 2340, and 3750 ng/g, respectively(10). **Ethyl acetate** was detected in beer at a concentration of 8 ppm(11). **Ethyl acetate** was identified as a volatile compound in kiwi fruit, comprising 3.9, 4.7, and 1.6% of the components in mature, ripe, and very ripe fruit, respectively(12). It was also identified as a volatile component of pineapple guava at a concentration of 0.11 ug/g(13). Fresh grapefruit juice contained 1.65 ppm **ethyl acetate(**14). **Ethyl acetate** was identified in mature and overripe guava fruits at concentrations of 614.1 and 8884.2 ug/kg, respectively(15). It was identified as a volatile flavor component of the strawberry variety Sivetta and in Golden Delicious apples(16).

Environmental Standards & Regulations:

FIFRA Requirements:

Residues of **ethyl acetate** are exempted from the requirement of a tolerance when used as a solvent or cosolvent in accordance with good agricultural practices as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops or to raw agricultural commodities after harvest.
[40 CFR 180.1001(c) (7/1/97)]**PEER REVIEWED**

As the federal pesticide law FIFRA directs, EPA is conducting a comprehensive review of older pesticides to consider their health and environmental effects and make decisions about their future use. Under this pesticide reregistration program, EPA examines health and safety data for pesticide active ingredients initially registered before November 1, 1984, and determines whether they are eligible for reregistration. In addition, all pesticides must meet the new safety standard of the Food Quality Protection Act of 1996. Pesticides for which EPA had not issued Registration Standards prior to the effective date of FIFRA, as amended in 1988, were divided into three lists based upon their potential for human exposure and other factors, with List B containing pesticides of greater concern and List D pesticides of less concern. **Ethyl acetate** is found on List D. Case No: 4005; Pesticide type: insecticide, herbicide, antimicrobial; Case Status: OPP is reviewing data from the pesticide's producers regarding its

human health and/or environmental effects, or OPP is determining the pesticide's eligibility for reregistration and developing the Reregistration Eligibility Decision (RED) document.; Active ingredient (AI): **Ethyl acetate;** AI Status: The active ingredient is no longer contained in any registered pesticide products ... "cancelled."

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 5000 lb or 2270 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/97)]**PEER REVIEWED**

RCRA Requirements:

U112; As stipulated in 40 CFR 261.33, when **ethyl acetate,** as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).
[40 CFR 261.33 (7/1/97)]**PEER REVIEWED**

F003; When **ethyl acetate** is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F003), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/97)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Ethyl acetate** is produced, as an intermediate or final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/97)]**PEER REVIEWED**

FDA Requirements:

Certification of this color additive when used as a diluent (in inks for marking fruit & vegetables) is not

necessary for the protection of the public health and therefore batches thereof are exempt from the requirements of section 706(c) of the Federal Food, Drug, and Cosmetic Act. /Restrictions incl no residue./

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-129]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. ... Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. G-129]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All

equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.

Prior History of Accidents:

The wreck of the MV Ariadne, a Panamanian flag container ship, is examined as a case study of a hazardous substance emergency response in a third world country. /The ship/, carrying a cargo of heavy fuel oil, tetraethyl lead, xylene, toluene, methyl isobutyl ketone, butyl acetate, **ethyl acetate,** and acetone was grounded while departing the harbor of Mogadishu, Somalia. The Somalian government requested a team of technical advisors to help respond appropriately to the emergency. The major issues addressed by the advisory team were the need for additional salvage equipment and expertise, the danger of toxic fumes from the fire and explosions aboard the ship, the presence and possible release of tetraethyl lead, possible port blockage by the wreck, recovery of the chemical drums, and the extent of environmental damage caused by the release of oil, pesticides, and tetraethyl lead into the harbor. ...

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or

detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to disperse vapors and dilute standing pools of liquid.

Work clothing that becomes wet should be immediately removed due to its flammability hazard.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

An analysis of breakthrough times of low boiling organic solvent vapors in a commercial respirator cartridge under steady state and pulsating flow conditions was performed. A KGC-8 respirator cartridge packed with 22.5 grams of activated charcoal was exposed to 0, 100, 300, or 900 ppm carbon-tetrachloride, **ethyl-acetate,** methyl-acetate, acetone, or dichloromethane vapor under steady state or pulsed flow conditions in custom built apparatus. The steady state flow condition was achieved by setting the respirator cartridge in its holder and passing each solvent vapor through it at a flow rate of 30 liter per minute (l/min). The pulsating flow condition was achieved placing the respirator cartridge in a Tedler bag, expanding the bag by introducing each test vapor, and 'inhaling' the test vapor through the respirator cartridge using a breathing machine drawing 1.5 liters air per cycle at the rate 20 cycles/min. The total flow rate was adjusted to be similar to the 301/min rate utilized the steady state flow experiments. Solvent vapor concentrations were measured upstream and downstream from the cartridge by gas chromatography. Breakthrough times were determined as the time required for the solvent vapor concentrations downstream from the cartridge to increase to 5 ppm. The data were analyzed by logistic regression techniques. After converting the data to logarithms, the breakthrough times of all five solvents

were linearly, inversely proportional to their initial concentrations under both steady state and pulsed flow conditions. The slopes of the lines were smaller for the solvents with the lower boiling points. The ratios of the breakthrough times measured under the pulsating flow to the steady slate flow condition (B/A ratio) varied from 0.77 to 0.71 for dichloromethane. The B/A ratios for the lOO ppm initial concentrations of the other four solvents varied only from 0.95 to 1.01. This indicated that except in the case of dichloromethane, there are no large differences in breakthrough tire under the two different flow conditions at lOO ppm. At the other concentrations, in each experiment as the concentration of the test vapor increased the breakthrough times under the pulsating flow condition became shorter compared to the steady state flow condition. /It was/ concluded that breakthrough of low boiling solvent vapors in respirator cartridges occurs earlier under pulsating flow than under steady state conditions.

ANALYTE: **ETHYL ACETATE.** MATRIX: AIR. PROCEDURE: ADSORPTION ON CHARCOAL, DESORPTION WITH CARBON DISULFIDE, GAS CHROMATOGRAPHY. RANGE: 704-2950 MG/CU M.
[U.S. Department of Health, Education Welfare, Public Health Service. Center for Disease Control, National Institute for Occupational Safety Health. NIOSH Manual ofAnalytical Methods. 2nd ed. Volumes 1-7. Washington, DC: U.S. Government Printing Office, 1977-present.,p. V2 S49]**PEER REVIEWED**

Residual solvents in pharmaceutical powders were determined by gas chromatography with a headspace injection system. The chromatography conditions and parameters of the injection system were optimized to enable the quantification by external standardization of 21 most common solvents in concn ranging from a few ppm to a few percent. Porapak Q (100-120 mesh) was used as the stationary phase with flame ionization detection.
[Guimbard JP et al; J chromatogr 403: 109-21 (1987)]**PEER REVIEWED**

A generalized GC method is described for the determinations of a wide variety of residual solvents and other volatile impurities in bulk pharmaceuticals. ... Analytical data from replicated determinations of 7 representative cmpd are reported.
[Haky JE, Stickney TM; J Chromatogr 321 (1): 137-44 (1985)]**PEER

REVIEWED**

The head space method for determining volatile gases was developed and compared with results obtained by the conventional purge and trap method. A gas chromatogram fitted with a retractable retrofit on column injectors and split inlet systems was used. The more highly volatile compounds /including **ethyl acetate/** were clearly evident by the method but were lost to breakthrough in the purge and trap method. Head space samples generated contained appreciable amounts of water and were dominated by lower molecular weight compounds under normal conditions.
[Takeoka G, Jennings W; J Chromatrogr Sci 22 (5): 177-84 (1984)]**PEER REVIEWED**

Esters in distilled liquors, spectrophotometric method. Esters including **ethyl acetate** react quantitatively with hydroxylamine in alkaline solutions to form a hydroxamic acid which, forms colored complex with ferric ions. Ester concentration is proportional to absorbance at 525 nm at constant alcohol concentration and is calculated from standard curves.

UNACCLIMATED SUBJECTS ... FOUND THE ODOR /OF **ETHYL ACETATE/** OBJECTIONABLY STRONG AT 200 PPM, AND MILD EYE, NOSE, AND THROAT IRRITATION AT 400 PPM.

[American Conference of Governmental Industrial Hygienists. Documentation of the Threshold Limit Values and Biological Exposure Indices. 5th ed. Cincinnati, OH:American Conference of Governmental Industrial Hygienists, 1986. 239]**PEER REVIEWED**

ETHYL ACETATE TESTED AT 10% IN PETROLATUM PRODUCED NO IRRITATION AFTER A 48-HOUR CLOSED PATCH TEST IN 25 HUMAN SUBJECTS. SENSITIZATION: A MAXIMIZATION TEST WAS CARRIED OUT ON 25 VOLUNTEERS. THE MATERIAL WAS TESTED AT A CONCN OF 10% IN PETROLATUM AND PRODUCED NO SENSITIZATION REACTIONS.

[Opdyke, D.L.J. (ed.). Monographs on Fragrance Raw Materials. New York: Pergamon Press, 1979. 341]**PEER REVIEWED**

SYMPTOMATOLOGY (acute intoxication): 1. Early emotional lability: exhilaration, boastfulness, talkativeness, remorse, and belligerency. 2. Impaired motor coordination: slowed reaction time, slurred speech, ataxia. 3. Sensory disturbances: diplopia, vertigo. 4. Flushing of face, rapid pulse, sweating. 5. Nausea and vomiting. Eventual incontinence of urine and feces. 6. Drowsiness, stupor, and finally coma, with impaired or absent tendon reflexes. Convulsive episodes may indicate hypoglycemia. 7. Pupils dilated or normal. 8. Peripheral vascular collapse (shock); hypotension, tachycardia, cold pale skin, hypothermia. 9. Slow stentorous respiration. 10. Death from respiratory or circulatory failure or from aspiration pneumonitis. 11. During convalescence: postalcoholic headache and gastritis; infections, alcoholic psychoses. /Ethyl alcohol/

[Gosselin, R.E., R.P. Smith, H.C. Hodge. Clinical Toxicology of Commercial Products. 5th ed. Baltimore: Williams and Wilkins, 1984.,p. III-169-70]**PEER REVIEWED**

Poison by inhalation. Moderately toxic by intraperitoneal and subcutaneous routes. Mildly toxic by ingestion. Human systemic effects by inhalation: olfactory changes, conjunctiva irritation, and

pulmonary changes. Human eye irritant. Irritating to mucous surfaces ... and is also mildly narcotic. On repeated or prolonged exposures, it causes conjunctival irritation and corneal clouding. High concentrations have a narcotic effect and can cause congestion of the liver and kidneys. Chronic poisoning has been described as producing anemia, leucocytosis (transient increase in the white blood cell count), and cloudy swelling, and fatty degeneration of the viscera.
[Lewis, R.J. Sax's Dangerous Properties of Industrial Materials. 9th ed. Volumes 1-3. New York, NY: Van Nostrand Reinhold, 1996. 1514]**PEER REVIEWED**

ETHYL ACETATE HAS ... REPUTATION OF BEING ONE OF THE LEAST TOXIC OF THE VOLATILE ORGANIC SOLVENTS.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 569]**PEER REVIEWED**

IRRITANT EFFECT OF **ETHYL ACETATE** IS LESS STRONG THAN THAT OF PROPYL ACETATE OR BUTYL ACETATE.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Volumes I and II. New York: McGraw-Hill Book Co., 1971. 477]**PEER REVIEWED**

... ALLEGED ILL EFFECTS OF **ETHYL ACETATE** HAVE OCCURRED DURING ITS INTENSIVE USE DURING EARLIER YEARS ... IMPURITIES MAY HAVE BEEN PRESENT OR IT MAY HAVE BEEN USED WITHOUT DUE CARE AND OFTEN IN COMBINATION WITH OTHER SOLVENTS.
[Snyder, R. (ed.). Ethel Browning's Toxicity and Metabolism of Industrial Solvents. Second Edition. Volume 3 Alcohols and Esters. New York, NY: Elsevier, 1992. 239]**PEER REVIEWED**

THE ALIPHATIC ESTERS USED AS LACQUER SOLVENTS, PRIMARILY **ETHYL ACETATE** AND BUTYL ACETATE, HAVE ... /SRP: CNS DEPRESSANT/ PROPERTIES WHICH ARE LESS PROMINENT THAN THOSE ASSOCIATED WITH THE CHLORINATED HYDROCARBONS.
[Hamilton, A., and H. L. Hardy. Industrial Toxicology. 3rd ed. Acton, Mass.: Publishing Sciences Group, Inc., 1974. 313]**PEER REVIEWED**

/Seventeen/ track team runners were evaluated after complaining of wheezing coughing, rhinitis, or shortness of breath after practicing in a facility under construction. Investigation revealed levels of **ethyl acetate** and toluene low enough to meet federal guidelines but apparently sufficient to cause symptoms in the athletes. Therefore, current standards for regulating potentially toxic organic chemicals may be inadequate when aerobic exercise is performed in the polluted environment.
[Larson DC; Physician Sportsmed 13 (1): 76-79 (1985)]**PEER REVIEWED**

A survey of the uptake of 5-hydroxytryptamine (serotonin) in platelets of workers exposed to organic solvents was conducted. Blood samples were obtained from six males, ages 34 to 58, employed in a graphic paint manufacturing facility and from 50 nonexposed individuals, 25 to 56 years old. Platelets were isolated and incubated with (14)carbon labeled serotonin. The uptake of radiolabeled serotonin, serum concentrations of calcium, potassium, and sodium ions, platelet count, and blood pH were also

determined. Breathing zone concentrations of organic solvents were obtained and analyzed by gas chromatography. The platelet count of the exposed workers was less than that of the comparisons. Maximal uptake rates of serotonin by platelets from the exposed workers was significantly greater than that of the comparisons. No significant differences in blood ion concentrations or pH values in the workers or comparisons were noted. The total concentration of organic solvents in the breathing zones of the exposed subjects ranged from 13 to 111 ppm. Compounds identified were 2 to 68 ppm toluene and 34 to 78 ppm **ethyl acetate. /**It was/ concluded that platelets of workers are affected by exposure to paint solvents.
[Beving H; Scand J Work Environ Health 10 (4): 229-34 (1984)]**PEER REVIEWED**

Ethyl acetate vapor is irritating to the eyes and respiratory passages of man at concentrations above 400 ppm. ... Due to its irritating properties, employees will not voluntarily remain in such high concentrations. ... This substance is a defatting agent, and prolonged exposure may cause irritation of the skin. Painful conjunctival irritation may occur from splashes in the eye. No chronic systemic effects have been reported in humans.
[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981. 1]**PEER REVIEWED**

Overexposure to **ethyl acetate** may cause irritation of the eyes, nose, & throat. Severe overexposure may cause weakness, drowsiness, & unconsciousness.
[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981.]**PEER REVIEWED**

Humans exposed to a concn of 400 ppm in 1.4 mg/l **ethyl acetate** for a short time were effected by nose and throat irritation. /From table/
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 2981]**PEER REVIEWED**

... **Ethyl acetate** is an irritant of the conjuctiva and mucous membrane of the respiratory tract. Animal experiments have shown that, at very high concentrations, the ester has /CNS depressant/ and lethal effects; at concentrations of 20000 to 43000 ppm, there may be pulmonary edema with hemorrhages, symptoms of central nervous system depression, secondary anemia and damage of the liver. In man, concentrations of 400 ppm cause irritation of the nose and pharynx; cases have also been known of irritation of the conjunctiva with temporary opacity of the cornea. In rare cases exposure may cause sensitization of the mucous membrane and eruptions of the skin. The irritant effect of **ethyl acetate** is less strong than that of propyl acetate or butyl acetate.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 782]**PEER REVIEWED**

Skin, Eye and Respiratory Irritations:

Irritating to mucous surfaces, particularly the eyes, gums and respiratory passages ... . On repeated or prolonged exposures, it causes conjunctival irritation and corneal clouding.

Urine: Reference Ranges: Normal - Not established; Exposed - Not established; Toxic - Not stablished.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1256]**PEER REVIEWED**

Respiratory Symptom Questionnaires: Questionnaires have been published by the American Thoracic Society and the British Medical Research Council. These questionnaires have been found to be useful in identification of people with chronic bronchitis, however certain pulmonary function tests such as FEV 1 have been found to be better predictors of chronic airflow obstruction.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Chest Radiography: This test is widely used for assessing pulmonary disease. Chest radiographs have been found to be useful for detection of early lung cancer in asymptomatic people, especially for detection of peripheral tumors such as adenocarcinomas. However, even though OSHA mandates this test for exposure to some toxicants such as asbestos, there are conflicting views on its efficacy in detection of pulmonary disease.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Pulmonary Function Tests: The tests that have been found to be practical for population monitoring include: Spirometry and expiratory flow-volume curves; Determination of lung volumes; Diffusing

capacity for carbon monoxide; Single-breath nitrogen washout; Inhalation challenge tests; Serial measurements of peak expiratory flow; Exercise testing.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Sputum Cytology: Sputum cytology along with chest radiographs have been the standard procedures for detecting early lung cancer in asymptomatic patients. Sputum cytology has been found to be useful for detection of central tumors, especially squamous carcinomas. For this test to be effective, exfoliated respiratory mucosal cells must be present in the expectorated specimen. Pooling of sputum collected over 2-3 days may enhance the sensitivity of this test by increasing the yield of exfoliated cells in the specimen.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1257]**PEER REVIEWED**

Evaluation of Peripheral Neuropathy: Nerve conduction study; Electromyography; Quantitative sensory testing; Thermography.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Evaluation of Central Nervous System Effects: Evaluation of CNS effects can be performed through neuropsychological assessment, which consists of a clinical interview and administration of standardized personality and neuropsychological tests. The areas that the neuropsychology test batteries focus on include the domains of memory and attention; visuoperceptual, visual scanning, visuospatial, and visual memory; and motor speed and reaction time. There is limited data on which components of the test batteries are best indicators of early CNS effects.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Evaluation of Cranial Neuropathies: Evaluation of cranial nerve damage, as evidenced by symptoms such as loss of balance, visual function, smell, taste, or sensation on the face, can be accomplished through a physical examination focusing on tests such as: Smell assessment - standardized odor threshold and identification testing; Vision assessment - standard acuity tests, visual field tests, contrast sensitivity, and color vision measurements (vision assessment); Facial and Trigeminal Nerve assessment - blink reflex (pontogram); Vestibular assessment - pure tone audiometry for bone- and air-conducted sounds, threshold decay at 4 kHz, speech discrimination and speech reception thresholds, tympanograms and acoustic thresholds, electronystagmograms; Hearing assessment - audiometry testing.
[Ryan, R.P., C.E. Terry (eds.). Toxicology Desk Reference 4th ed. Volumes 1-3. Taylor & Francis, washington, D.C. 1997. 1258]**PEER REVIEWED**

Populations at Special Risk:

Employees /with chronic respiratory, skin, liver, or kidney disase may be/ at increased risk from **ethyl acetate.**

[Mackison, F. W., R. S. Stricoff, and L. J. Partridge, Jr. (eds.). NIOSH/OSHA - Occupational Health Guidelines for Chemical Hazards. DHHS(NIOSH) PublicationNo. 81-123 (3 VOLS). Washington, DC: U.S. Government Printing Office, Jan. 1981. 1]**PEER REVIEWED**

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 375,906 workers (87,691 of these are female) are potentially exposed to **ethyl acetate** in the US(1). Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used(SRC). **Ethyl acetate** was identified (relative abundance) in air samples collected where printing pastes (66%) and paints (30%) were used, in car repair shops (45%), and in various other industries (57%) in Belgium(2). Mean concentrations of **ethyl acetate** in air during parquet work in Finland were 119 ppm during installation with resin adhesives; 319 ppm during puttying; 72 ppm during sanding after puttying; 413 ppm during undercoat varnishing (nitrocellulose); 64 ppm during urea-formaldehyde varnishing; and 1 ppm during work with water-based varnishes(3). It was also detected in air during the use of contact adhesives at mean concentrations of 14 ppm during repair of a textile carpet (dispersion and contact adhesives); 83 ppm during repair of a textile carpet (contact adhesives only); 29 ppm during beading of textile carpets (contact adhesives only); and 71 ppm during repair of bathroom floor mats (dispersion and contact adhesives)(3). **Ethyl acetate** was detected in 36% of all air samples, at a mean concentration of 11 ppm, collected from Finnish furniture factories from 1975 to 1984(4). Breathing zone samples collected during spray painting contained **ethyl acetate** at a geometric mean concentration of 9.51 ppm(5). It was detected in the air of one auto paint shop at a concentration of 10.5 mg/cu m(6). **Ethyl acetate** was identified in 12% of 275 products (including thinners, degreasers, paints, inks, and dome reagents) used in workplaces in various industries(7). **Ethyl acetate** was identified in the breathing zone of shoe factory workers(8). **Ethyl acetate** was detected in the ambient air of shoe factory in Italy in Nov 1991 at median concentrations of 10 and 7 mg/cu m(9).

Poison by inhalation. Moderately toxic by intraperitoneal and subcutaneous routes. Mildly toxic by ingestion. Human systemic effects by inhalation: olfactory changes, conjunctiva irritation, and pulmonary changes. Human eye irritant. Irritating to mucous surfaces ... and is also mildly narcotic. On repeated or prolonged exposures, it causes conjunctival irritation and corneal clouding. High concentrations have a narcotic effect and can cause congestion of the liver and kidneys. Chronic

poisoning has been described as producing anemia, leucocytosis (transient increase in the white blood cell count), and cloudy swelling, and fatty degeneration of the viscera.

A survey of the uptake of 5-hydroxytryptamine (serotonin) in platelets of workers exposed to organic solvents was conducted. Blood samples were obtained from six males, ages 34 to 58, employed in a graphic paint manufacturing facility and from 50 nonexposed individuals, 25 to 56 years old. Platelets were isolated and incubated with (14)carbon labeled serotonin. The uptake of radiolabeled serotonin, serum concentrations of calcium, potassium, and sodium ions, platelet count, and blood pH were also determined. Breathing zone concentrations of organic solvents were obtained and analyzed by gas chromatography. The platelet count of the exposed workers was less than that of the comparisons. Maximal uptake rates of serotonin by platelets from the exposed workers was significantly greater than

that of the comparisons. No significant differences in blood ion concentrations or pH values in the workers or comparisons were noted. The total concentration of organic solvents in the breathing zones of the exposed subjects ranged from 13 to 111 ppm. Compounds identified were 2 to 68 ppm toluene and 34 to 78 ppm **ethyl acetate. /**It was/ concluded that platelets of workers are affected by exposure to paint solvents.

... **Ethyl acetate** is an irritant of the conjuctiva and mucous membrane of the respiratory tract. Animal experiments have shown that, at very high concentrations, the ester has /CNS depressant/ and lethal effects; at concentrations of 20000 to 43000 ppm, there may be pulmonary edema with hemorrhages, symptoms of central nervous system depression, secondary anemia and damage of the liver. In man, concentrations of 400 ppm cause irritation of the nose and pharynx; cases have also been known of irritation of the conjunctiva with temporary opacity of the cornea. In rare cases exposure may cause sensitization of the mucous membrane and eruptions of the skin. The irritant effect of **ethyl acetate** is less strong than that of propyl acetate or butyl acetate.

The following Overview, *** **ETHYL ACETATE ***,** is relevant for this HSDB record chemical.

Life Support:

```
  o   This overview assumes that basic life support measures
      have been instituted.
```

Clinical Effects:

```
SUMMARY OF EXPOSURE
 0.2.1.1 ACUTE EXPOSURE
   o   Ethyl acetate is low in toxicity.  It is a mild mucous
       membrane irritant, but is not caustic.  In high
       concentrations it may be a CNS depressant.  Animal
       studies have demonstrated pulmonary edema, decreased
       cardiac contractility, seizures and hepatic damage, but
       these have NOT been reported in humans.
 0.2.1.2 CHRONIC EXPOSURE
   o   Chronic poisoning has been described as producing
       anemia, leucocytosis (transient increase in the white
       blood cell count) and cloudy swelling, and fatty
       degeneration of the viscera in animal studies (Sax &
       Lewis, 1989).
HEENT
 0.2.4.1 ACUTE EXPOSURE
   o   Ethyl acetate is irritating to the conjunctivae but
       leaves no residual effects.  Nose and throat irritation
       is seen at levels greater than 400 ppm for 3 to 5
       minutes.
NEUROLOGIC
 0.2.7.1 ACUTE EXPOSURE

```

acetate has been associated with poorer performance on neurobehavioral tests. High concentrations orally administered to rabbits caused lack of coordination. High concentrations have intoxicating properties in animals and would be expected to cause narcosis in humans.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Drying as well as skin defatting and cracking may be seen with dermal application. Sensitizations to **ethyl acetate** have been reported but are rare.

Laboratory:

- Various techniques are available, primarily using gas chromatography or spectrometric techniques. Toxic levels have not been established.

Treatment Overview:

SUMMARY EXPOSURE

- Because of rapid hydrolysis and low toxicity, inhalation or ingestion of ethyl acetates seldom requires treatment. Patients should be monitored for CNS depression if large amounts have been ingested.

ORAL EXPOSURE

- Emesis or activated charcoal is unlikely to be necessary due to the low toxicity of these compounds.
- No specific antidotes or treatments are available. Monitor patients ingesting large amounts for CNS depression, respiratory depression, and decreased cardiac contractility.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly

with soap and water. A physician may need to examine the area if irritation or pain persists.

Range of Toxicity:

- No adverse symptoms were noted in workers exposed to 375 to 1,500 ppm for several months. Humans find concentrations greater than 200 ppm objectionable because of the strong odor. 400 ppm caused nose and throat irritation. The TLV is 400 ppm (1,400 mg/m(3)).

[Rumack BH: POISINDEX(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001. Hall AH & Rumack BH (Eds):TOMES(R) Information System. Micromedex, Inc., Englewood, CO, 2001; CCIS Volume 107, edition exp February, 2001.] **PEER REVIEWED**

Antidote and Emergency Treatment:

For basic treatment: Establish a patent airway. Suction if necessary. Watch for signs of respiratory insufficiency and assist ventilations if necessary. Administer oxygen by nonrebreather mask at 10 to 15 L/min. Monitor for pulmonary edema and treat if necessary ... . Monitor for shock and treat if necessary ... . For eye contamination, flush eyes immediately with water. Irrigate each eye continuously with normal saline during transport ... . Do not use emetics. For ingestion, administer activated charcoal ... . /Esters and related compounds/

[Bronstein, A.C., P.L. Currance; Emergency Care for Hazardous Materials Exposure. 2nd ed. St. Louis, MO. Mosby Lifeline. 1994. 221]**PEER REVIEWED**

For advanced treatment: Consider orotracheal or nasotracheal intubation for airway control in the patient who is unconscious. Positive-pressure ventilation techniques with a bag-valve-mask device may be beneficial. Monitor cardiac rhythm and treat arrhythmias if necessary ... . Start an IV with D5W TKO /SRP: To keep open, "minimal flow rate"/. Ringer's if signs of hypovolemia are present. Watch for signs of fluid overload. For hypotension with signs of hypovolemia, administer fluid cautiously. Consider vasopressors if patient is hypotensive with a normal fluid volume. Watch for signs of fluid overload ... . Consider drug therapy for pulmonary edema ... . Use proparacaine hydrochloride to assist eye irrigation ... . /Esters and related compounds/

The following Overview, *** **ETHYL ACETATE ***,** is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- **Ethyl acetate** is low in toxicity. It is a mild mucous membrane irritant, but is not caustic. In high concentrations it may be a CNS depressant. Animal studies have demonstrated pulmonary edema, decreased cardiac contractility, seizures and hepatic damage, but these have NOT been reported in humans.

0.2.1.2 CHRONIC EXPOSURE

- Chronic poisoning has been described as producing anemia, leucocytosis (transient increase in the white blood cell count) and cloudy swelling, and fatty degeneration of the viscera in animal studies (Sax & Lewis, 1989).

HEENT

0.2.4.1 ACUTE EXPOSURE

- **Ethyl acetate** is irritating to the conjunctivae but leaves no residual effects. Nose and throat irritation is seen at levels greater than 400 ppm for 3 to 5 minutes.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Chronic exposure to solvent mixtures including **ethyl acetate** has been associated with poorer performance on neurobehavioral tests. High concentrations orally

administered to rabbits caused lack of coordination. High concentrations have intoxicating properties in animals and would be expected to cause narcosis in humans.

Chinese hamsters were exposed to **ethyl acetate ...** known to be a strong inducer of aneuploidy in the yeast Saccaromyces cerevisiae. This solvent yielded negative results in the micronucleus test, whereas the vinca alkaloid vindesine used as a positive control substance proved to act as a spindle poison in mammals in vivo.
[Basler A; Mutat Res 174 (1): 11-3 (1986)]**PEER REVIEWED**

Leucopenia without change in differential or red blood cell counts was observed in rats exposed for 4 hr to increasing air concentration of ... **ethyl acetate. ...** This effect was abolished by adrenalectomy. This solvent caused leucopenia only when exposure reached the irritant level. It is discussed that stress associated with the irritative effect of chemicals can confound specific hematological effects.
[Brondeau MT et al; J Appl Toxicol 10 (2): 83-6 (1990)]**PEER REVIEWED**

In order to determine the lung disease potential of waterproofing sprays, several components of suspected sprays, as well as a commercial spray, were tested on CD-l-mice. Mice placed in inhalation chambers were exposed to aerosols containing one or more of the suspected components, including N-heptane, **ethyl-acetate,** fluororesin, silicone, and a commercial spray. An intermittent inhalation methods was used to prevent the solvents from causing anesthetic death. Mice were sacrificed 1 hour after the end of exposure. The lungs of both exposed and control mice were isolated and examined microscopically for any changes. The amounts released of the were similar. Mice exposed to the commercial and fluororesin sprays were cyanotic and depressed for 1 hour, while those exposed to the other sprays were cyanotic for only several minutes. In almost all mice exposed to the commercial spray, significant changes relative to the controls included a thickened pulmonary alveolar septa, cellular infiltration, fused and hemorrhaged alveolar walls, and diminished alveoli. Fluororesin particles were found in the alveolar space. Significantly more pronounced pathological changes were discovered in mice exposed to the fluororesin spray, relative to the commercial spray. In mice exposed to the silicone spray, significant differences were observed in alveolar collapse and hemorrhage, compared to the controls. The lungs of mice exposed to the N-heptane, **ethyl-acetate,** and fluororesin free sprays were similar to control lungs. In mice exposed to the silicon resin free spray, significant changes, relative to the commercial spray group, included alveolar collapse, hyperemia, hemorrhage and increased thickness and cellular infiltration of the septum. /It was/ concluded that **ethyl-acetate** and N-heptane contained in waterproofing sprays do not cause pulmonary disorders. Instead, fluororesin is implicated in respiratory disorders caused by such sprays.
[Yamashita M, Tanaka J; J Toxicol, Clin Toxicol 33 (6): 631-7 (1995)]**PEER REVIEWED**

The neurotoxic effects of inhaled amyl-acetate, **ethyl-acetate,** and n-butyl-acetate were investigated in mice. Male CFW-albino-mice were exposed to up to 40,000 ppm amyl-acetate, 2,000 ppm **ethyl-acetate,** or 8,000 ppm n-butyl-acetate for 20 minutes in an exposure chamber. Acute neurotoxic effects were assessed by measuring locomotor activity and functional observational battery. Similar acute behavioral effects on locomotor activity were observed in mice following **ethyl-acetate** and n-butyl-acetate exposure, with amyl-acetate inducing little neurotoxic effect. Exposure to the compounds caused changes in posture, with decreased arousal and rearing; increased central nervous system excitability, as manifested by increased tonic and clonic movements; and increased autonomic effects. Also, decreased mobility and righting reflex, and an elevated reaction to sensory stimuli were observed. Handling induced convulsions were produced in some mice following acute exposure; potency differences were observed. Significant decreases in locomotor activity were seen with exposure to **ethyl-acetate** and n-butyl-acetate at the highest concentrations tested, and minimally effective levels for activity decreasing effects were 2,000 and 8,000 ppm for **ethyl-acetate** and n-butyl-acetate, respectively. Rapid recovery was seen in mice after removal from exposure. /It was/ concluded that acute exposure to acetyl-acetate, n-butyl-acetate, and **ethyl-acetate** produces acute neurobehavioral effects which differ from the effects produced by exposure to alkylbenzenes and halogenated hydrocarbon solvents.

Chinese hamsters were exposed to **ethyl acetate ...** known to be a strong inducer of aneuploidy in the yeast Saccaromyces cerevisiae. This solvent yielded negative results in the micronucleus test, whereas the vinca alkaloid vindesine used as a positive control substance proved to act as a spindle poison in mammals in vivo.
[Basler A; Mutat Res 174 (1): 11-3 (1986)]**PEER REVIEWED**

Leucopenia without change in differential or red blood cell counts was observed in rats exposed for 4 hr

to increasing air concentration of ... **ethyl acetate. ...** This effect was abolished by adrenalectomy. This solvent caused leucopenia only when exposure reached the irritant level. It is discussed that stress associated with the irritative effect of chemicals can confound specific hematological effects.
[Brondeau MT et al; J Appl Toxicol 10 (2): 83-6 (1990)]**PEER REVIEWED**

In order to determine the lung disease potential of waterproofing sprays, several components of suspected sprays, as well as a commercial spray, were tested on CD-l-mice. Mice placed in inhalation chambers were exposed to aerosols containing one or more of the suspected components, including N-heptane, **ethyl-acetate,** fluororesin, silicone, and a commercial spray. An intermittent inhalation methods was used to prevent the solvents from causing anesthetic death. Mice were sacrificed 1 hour after the end of exposure. The lungs of both exposed and control mice were isolated and examined microscopically for any changes. The amounts released of the were similar. Mice exposed to the commercial and fluororesin sprays were cyanotic and depressed for 1 hour, while those exposed to the other sprays were cyanotic for only several minutes. In almost all mice exposed to the commercial spray, significant changes relative to the controls included a thickened pulmonary alveolar septa, cellular infiltration, fused and hemorrhaged alveolar walls, and diminished alveoli. Fluororesin particles were found in the alveolar space. Significantly more pronounced pathological changes were discovered in mice exposed to the fluororesin spray, relative to the commercial spray. In mice exposed to the silicone spray, significant differences were observed in alveolar collapse and hemorrhage, compared to the controls. The lungs of mice exposed to the N-heptane, **ethyl-acetate,** and fluororesin free sprays were similar to control lungs. In mice exposed to the silicon resin free spray, significant changes, relative to the commercial spray group, included alveolar collapse, hyperemia, hemorrhage and increased thickness and cellular infiltration of the septum. /It was/ concluded that **ethyl-acetate** and N-heptane contained in waterproofing sprays do not cause pulmonary disorders. Instead, fluororesin is implicated in respiratory disorders caused by such sprays.
[Yamashita M, Tanaka J; J Toxicol, Clin Toxicol 33 (6): 631-7 (1995)]**PEER REVIEWED**

The neurotoxic effects of inhaled amyl-acetate, **ethyl-acetate,** and n-butyl-acetate were investigated in mice. Male CFW-albino-mice were exposed to up to 40,000 ppm amyl-acetate, 2,000 ppm **ethyl-acetate,** or 8,000 ppm n-butyl-acetate for 20 minutes in an exposure chamber. Acute neurotoxic effects were assessed by measuring locomotor activity and functional observational battery. Similar acute behavioral effects on locomotor activity were observed in mice following **ethyl-acetate** and n-butyl-acetate exposure, with amyl-acetate inducing little neurotoxic effect. Exposure to the compounds caused changes in posture, with decreased arousal and rearing; increased central nervous system excitability, as manifested by increased tonic and clonic movements; and increased autonomic effects. Also, decreased mobility and righting reflex, and an elevated reaction to sensory stimuli were observed. Handling induced convulsions were produced in some mice following acute exposure; potency differences were observed. Significant decreases in locomotor activity were seen with exposure to **ethyl-acetate** and n-butyl-acetate at the highest concentrations tested, and minimally effective levels for activity decreasing effects were 2,000 and 8,000 ppm for **ethyl-acetate** and n-butyl-acetate, respectively. Rapid recovery was seen in mice after removal from exposure. /It was/ concluded that acute exposure to acetyl-acetate, n-butyl-acetate, and **ethyl-acetate** produces acute neurobehavioral effects which differ from the effects produced by exposure to alkylbenzenes and halogenated hydrocarbon solvents.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Ethyl acetate's production and use as a pharmaceutic aid, in artificial fruit essences, and as a solvent may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 93 mm Hg at 25 deg C indicates **ethyl acetate** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **ethyl acetate** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 9.4 days. If released to soil, **ethyl acetate** is expected to have high mobility based upon an estimated Koc of 59. Volatilization from moist soil surfaces is expected to occur based upon a Henry's Law constant of 1.34X10-4 atm-cu m/mole. **Ethyl acetate's** vapor pressure indicates the potential for volatilization from dry soil surfaces exists. Biodegradation is expected to be an important process in both soil and water, based upon **ethyl acetate's** biodegradation in aqueous screening studies. 93% biodegradation was observed in a complete mix continuous-flow activated sludge system. 26.6 and 57.1% of **ethyl acetate'**s theoretical BOD was reached in 5 days using the standard dilution method and seawater dilution method, respectively. If released into water, **ethyl acetate** is not expected to adsorb to suspended solids and sediment in water based on the estimated Koc. Volatilization from water surfaces is expected to be an important fate process based on **ethyl acetate's** Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 8.9 hours and 5.6 days, respectively. An estimated BCF of 3.2 suggests the potential for bioconcentration in aquatic organisms is low. **Ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years. Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used or where adhesives, thinners, degreasers, paints, inks, and dome reagents are used. The general population may be exposed to **ethyl acetate** via inhalation of ambient air, ingestion of food and drinking water, or dermal contact with consumer products containing this compound. (SRC)
PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 375,906 workers (87,691 of these are female) are potentially exposed to **ethyl acetate** in the US(1). Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used(SRC). **Ethyl acetate** was identified (relative abundance) in air samples collected where printing pastes (66%) and paints (30%) were used, in car repair shops (45%), and in various other industries (57%) in Belgium(2). Mean concentrations of **ethyl acetate** in air during parquet work in Finland were 119 ppm during installation with resin adhesives; 319 ppm during puttying; 72 ppm during sanding after puttying; 413 ppm during undercoat varnishing (nitrocellulose); 64 ppm during urea-formaldehyde varnishing; and 1 ppm during work with water-based varnishes(3). It was also detected in air during the use of contact adhesives at mean concentrations of 14 ppm during repair of a textile carpet (dispersion and contact adhesives); 83 ppm during repair of a textile carpet (contact adhesives only); 29 ppm during beading of textile carpets (contact adhesives only); and 71 ppm during repair of bathroom floor mats (dispersion and contact adhesives)(3). **Ethyl acetate** was detected in 36%

of all air samples, at a mean concentration of 11 ppm, collected from Finnish furniture factories from 1975 to 1984(4). Breathing zone samples collected during spray painting contained **ethyl acetate** at a geometric mean concentration of 9.51 ppm(5). It was detected in the air of one auto paint shop at a concentration of 10.5 mg/cu m(6). **Ethyl acetate** was identified in 12% of 275 products (including thinners, degreasers, paints, inks, and dome reagents) used in workplaces in various industries(7). **Ethyl acetate** was identified in the breathing zone of shoe factory workers(8). **Ethyl acetate** was detected in the ambient air of shoe factory in Italy in Nov 1991 at median concentrations of 10 and 7 mg/cu m(9).

Environmental Biodegradation:

ANAEROBIC: **Ethyl acetate** has been demonstrated to be amenable to anaerobic biodegradation(1). It was mineralized (>75% of theoretical methane production) in 10% sludge from a secondary digester within 8 weeks(2). 96% utilization occurred in an anaerobic reactor with a 20 day retention time(3). **Ethyl acetate,** at a concentration of 1000 mg/l, was readily degraded in batch reactors containing anaerobic solids from an industrial anaerobic digester with some exposure to **ethyl acetate(**4). 100% loss of **ethyl acetate** was observed in aquifer slurries amended with sulfate and nitrate following 244 days and 85 days incubation, respectively(5). 94% of theoretical methane production was observed after incubation in sediment and groundwater collected from the methanogenic portion of an anoxic aquifer polluted by municipal landfill leachate(6).

A review concluded that **ethyl acetate** is easily removed by biological treatment(1). Reported 5 day BOD values using a sewage inoculum range from 36-68% of theoretical(2-5) with the value being somewhat reduced in salt water(2). One investigator reported that **ethyl acetate** was completely degraded in 20 hr using activated sludge(6). In a bench-scale continuous-flow activated sludge reactor with an 8 hour retention time, 99.9% removal (including 17% volatilization loss) was obtained, with 80% of the theoretical BOD(7). **Ethyl acetate** was 90% biooxidized in a 20-day BOD test using a filtered raw sewage seed; it was biooxidized 77% in a 28-day OECD closed-bottle test(8). A screening procedure that was systematically applied to a large number of organic chemicals ranked **ethyl acetate** as being completely biodegraded in a short time by general microorganisms(9). After a 5 hr lag, 43 to 53% of theoretical BOD was obtained in 50 to 70 hr(9). In screening tests, **ethyl acetate,** present at a concentration of 5 ppm, reached 26.6 and 57.1% of its theoretical BOD in 5 days using the standard

dilution method and seawater dilution method, respectively(10). 99.9% removal of **ethyl acetate** was observed in a complete mix continuous-flow activated sludge system; 93% of this removal was attributed to biodegradation(11).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **ethyl acetate** with photochemically-produced hydroxyl radicals is 1.6X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 10 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1,SRC). The observed rate constant for the vapor-phase reaction of **ethyl acetate** with nitrate radicals is 1.4X10-17 cu cm/molecule-sec(2). This corresponds to an atmospheric half-life of about 16 years at an average nighttime nitrate radical concentration of 2X10+8 molecules/cu cm (nitrate radicals are unstable in sunlight)(3,SRC). The rate constant for the reaction of **ethyl acetate** with hydroxyl radicals in aqueous solution is 4.0X10+8 L/mol sec(4). This corresponds to a half-life of about 5.5 years(SRC) at an average aqueous hydroxyl radical concentration of 1X10-17 mol/l(5). Simple esters are resistant to hydrolysis; **ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years(6).

Environmental Bioconcentration:

An estimated BCF of 3.2 was calculated for **ethyl acetate(**SRC), using a log Kow of 0.73(1) and a regression-derived equation(2). According to a classification scheme(3), this BCF suggests the potential for bioconcentration in aquatic organisms is low(SRC).
[(1) Hansch C et al; Exploring QSAR. Hydrophobic, Electronic, and Steric Constants. ACS Prof Ref Book. Heller SR (consult ed) Washington,DC: Amer Chem Soc p. 9 (1995) (2) Lyman WJ et al; Handbook of Chemical Property Estimation Methods. Washington DC: Amer Chem Soc pp. 5-4, 5-10 (1990) (3) Franke C et al; Chemosphere 29: 1501-14 (1994)]**PEER REVIEWED**

Soil Adsorption/Mobility:

The Koc of **ethyl acetate** is estimated as 59(SRC), using a log Kow of 0.73(1) and a regression-derived equation(2,SRC). According to a classification scheme(3), this estimated Koc value suggests that **ethyl acetate** is expected to have high mobility in soil(SRC).
[(1) Hansch C et al; Exploring QSAR. Hydrophobic, Electronic, and Steric Constants. ACS Prof Ref Book. Heller SR (consult ed) Washington,DC: Amer Chem Soc p. 9 (1995) (2) Lyman WJ et al; Handbook of Chemical Property Estimation Methods. Washington,DC: Amer Chem Soc pp. 4-9 (1990) (3) Swann RL et al; Res Rev 85: 23 (1983)]**PEER REVIEWED**

Volatilization from Water/Soil:

The Henry's Law constant for **ethyl acetate** is 1.34X10-4 atm-cu m/mole(1). This Henry's Law constant indicates that **ethyl acetate** is expected to volatilize from water surfaces(2,SRC). Based on this Henry's Law constant, the estimated volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec) is estimated as 8.9 hours(2,SRC). The estimated volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec) is estimated as 5.6 days(2,SRC). **Ethyl acetate's** Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). The potential for volatilization of **ethyl acetate** from dry soil surfaces may exist(SRC) based on a vapor pressure of 93 mm Hg(3). 7% of the 99.9% removal observed in a continuous flow activated sludge system was attributed to stripping(4).

Environmental Fate/Exposure Summary:

Ethyl acetate's production and use as a pharmaceutic aid, in artificial fruit essences, and as a solvent may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 93 mm Hg at 25 deg C indicates **ethyl acetate** will exist solely as a vapor in the ambient atmosphere. Vapor-phase **ethyl acetate** will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 9.4 days. If released to soil, **ethyl acetate** is expected to have high mobility based upon an estimated Koc of 59. Volatilization from moist soil surfaces is expected to occur based upon a Henry's Law constant of 1.34X10-4 atm-cu m/mole. **Ethyl acetate's** vapor pressure indicates the potential for volatilization from dry soil surfaces exists. Biodegradation is expected to be an important process in both soil and water, based upon **ethyl acetate's** biodegradation in aqueous screening studies. 93% biodegradation was observed in a complete mix continuous-flow activated sludge system. 26.6 and 57.1% of **ethyl acetate'**s theoretical BOD was reached in 5 days using the standard dilution method and seawater dilution method, respectively. If released into water, **ethyl acetate** is not expected to adsorb to suspended solids and sediment in water based on the estimated Koc. Volatilization from water surfaces is expected to be an important fate process based on **ethyl acetate's** Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 8.9 hours and 5.6 days, respectively. An estimated BCF of 3.2 suggests the potential for bioconcentration in aquatic organisms is low. **Ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years. Occupational exposure to **ethyl acetate** may occur through inhalation and dermal contact with this compound at workplaces where **ethyl acetate** is produced or used or where adhesives, thinners, degreasers, paints, inks, and dome reagents are used. The general population may be exposed to **ethyl acetate** via inhalation of ambient air, ingestion of food and drinking water, or dermal contact with consumer products containing this compound. AQUATIC FATE: Based on a classification scheme(1), an estimated Koc value of 59(SRC), determined from a log Kow of 0.73(2) and a regression-derived equation(3), indicates that **ethyl acetate** is not expected to adsorb to suspended solids and sediment in water(SRC). **Ethyl acetate** is expected to volatilize from water surfaces(3,SRC) based on a Henry's Law constant of 1.34X10-4 atm-cu m/mole(4). Estimated volatilization half-lives for a model river and model lake are 8.9 hours and 5.6 days, respectively(3,SRC). According to a classification scheme(5), an estimated BCF of 3.2(3,SRC), from the log Kow(2), suggests the potential for bioconcentration in aquatic organisms is low(SRC). Simple esters are resistant to hydrolysis; **ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years(6). Biodegradation is expected to be an important process in aquatic systems(SRC), based upon aqueous screening studies(7,8). **Ethyl acetate** reached 26.6 and 57.1% of its theoretical BOD in 5 days using the standard dilution method and seawater dilution method, respectively(7). 99.9% removal of **ethyl acetate** was observed in a complete mix continuous-flow activated sludge system; 93% of this removal was attributed to biodegradation(8). 94% of theoretical methane production was observed after incubation in sediment and groundwater collected from the methanogenic portion of an anoxic aquifer polluted by municipal landfill leachate(9).

ATMOSPHERIC FATE: According to a model of gas/particle partitioning of semivolatile organic compounds in the atmosphere(1), **ethyl acetate,** which has a vapor pressure of 93 mm Hg at 25 deg C(2), is expected to exist solely as a vapor in the ambient atmosphere. Vapor-phase **ethyl acetate** is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals(SRC); the half-life for this reaction in air is estimated to be 10 days(3,SRC).

Environmental Biodegradation:

ANAEROBIC: **Ethyl acetate** has been demonstrated to be amenable to anaerobic biodegradation(1). It was mineralized (>75% of theoretical methane production) in 10% sludge from a secondary digester within 8 weeks(2). 96% utilization occurred in an anaerobic reactor with a 20 day retention time(3). **Ethyl acetate,** at a concentration of 1000 mg/l, was readily degraded in batch reactors containing anaerobic solids from an industrial anaerobic digester with some exposure to **ethyl acetate(**4). 100% loss of **ethyl acetate** was observed in aquifer slurries amended with sulfate and nitrate following 244 days and 85 days incubation, respectively(5). 94% of theoretical methane production was observed after incubation in sediment and groundwater collected from the methanogenic portion of an anoxic aquifer polluted by municipal landfill leachate(6).

A review concluded that **ethyl acetate** is easily removed by biological treatment(1). Reported 5 day BOD values using a sewage inoculum range from 36-68% of theoretical(2-5) with the value being somewhat reduced in salt water(2). One investigator reported that **ethyl acetate** was completely degraded in 20 hr using activated sludge(6). In a bench-scale continuous-flow activated sludge reactor with an 8 hour retention time, 99.9% removal (including 17% volatilization loss) was obtained, with 80% of the theoretical BOD(7). **Ethyl acetate** was 90% biooxidized in a 20-day BOD test using a filtered raw sewage seed; it was biooxidized 77% in a 28-day OECD closed-bottle test(8). A screening procedure that was systematically applied to a large number of organic chemicals ranked **ethyl acetate** as being completely biodegraded in a short time by general microorganisms(9). After a 5 hr lag, 43 to 53% of theoretical BOD was obtained in 50 to 70 hr(9). In screening tests, **ethyl acetate,** present at a concentration of 5 ppm, reached 26.6 and 57.1% of its theoretical BOD in 5 days using the standard dilution method and seawater dilution method, respectively(10). 99.9% removal of **ethyl acetate** was observed in a complete mix continuous-flow activated sludge system; 93% of this removal was attributed to biodegradation(11).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of **ethyl acetate** with photochemically-produced hydroxyl radicals is 1.6X10-12 cu cm/molecule-sec at 25 deg C(1). This corresponds to an atmospheric half-life of about 10 days at an atmospheric concentration of 5X10+5 hydroxyl radicals per cu cm(1,SRC). The observed rate constant for the vapor-phase reaction of **ethyl acetate** with nitrate radicals is 1.4X10-17 cu cm/molecule-sec(2). This corresponds to an atmospheric half-life of about 16 years at an average nighttime nitrate radical concentration of 2X10+8 molecules/cu cm (nitrate radicals are unstable in sunlight)(3,SRC). The rate constant for the reaction of **ethyl acetate** with hydroxyl radicals in aqueous solution is 4.0X10+8 L/mol sec(4). This corresponds to a half-life of about 5.5 years(SRC) at an average aqueous hydroxyl radical concentration of 1X10-17 mol/l(5). Simple esters are resistant to hydrolysis; **ethyl acetate's** hydrolysis half-life at 25 deg C and pH 7 is 2.0 years(6).

Volatilization from Water/Soil:

The Henry's Law constant for **ethyl acetate** is 1.34X10-4 atm-cu m/mole(1). This Henry's Law constant indicates that **ethyl acetate** is expected to volatilize from water surfaces(2,SRC). Based on this Henry's Law constant, the estimated volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec) is estimated as 8.9 hours(2,SRC). The estimated volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec) is estimated as 5.6 days(2,SRC). **Ethyl acetate's** Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). The potential for volatilization of **ethyl acetate** from dry soil surfaces may exist(SRC) based on a vapor pressure of 93 mm Hg(3). 7% of the 99.9% removal observed in a continuous flow activated sludge system was attributed to stripping(4).

Environmental Standards & Regulations:

FIFRA Requirements:

Residues of **ethyl acetate** are exempted from the requirement of a tolerance when used as a solvent or cosolvent in accordance with good agricultural practices as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops or to raw agricultural commodities after harvest.
[40 CFR 180.1001(c) (7/1/97)]**PEER REVIEWED**

As the federal pesticide law FIFRA directs, EPA is conducting a comprehensive review of older pesticides to consider their health and environmental effects and make decisions about their future use. Under this pesticide reregistration program, EPA examines health and safety data for pesticide active ingredients initially registered before November 1, 1984, and determines whether they are eligible for reregistration. In addition, all pesticides must meet the new safety standard of the Food Quality Protection Act of 1996. Pesticides for which EPA had not issued Registration Standards prior to the effective date of FIFRA, as amended in 1988, were divided into three lists based upon their potential for human exposure and other factors, with List B containing pesticides of greater concern and List D pesticides of less concern. **Ethyl acetate** is found on List D. Case No: 4005; Pesticide type: insecticide, herbicide, antimicrobial; Case Status: OPP is reviewing data from the pesticide's producers regarding its human health and/or environmental effects, or OPP is determining the pesticide's eligibility for reregistration and developing the Reregistration Eligibility Decision (RED) document.; Active ingredient (AI): **Ethyl acetate;** AI Status: The active ingredient is no longer contained in any registered pesticide products ... "cancelled."
[USEPA/OPP; Status of Pesticides in Registration, Reregistration and Special Review p.292 (Spring, 1998) EPA 738-R-98-002]**QC REVIEWED**

TSCA Requirements:

A testing consent order is in effect for **ethyl acetate** for health effects testing. FR citation: 1/23/95.
[40 CFR 799.5000 (7/1/97)]**PEER REVIEWED**

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 5000 lb or 2270 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/97)]**PEER REVIEWED**

RCRA Requirements:

U112; As stipulated in 40 CFR 261.33, when **ethyl acetate,** as a commercial chemical product or manufacturing chemical intermediate or an off-specification commercial chemical product or a manufacturing chemical intermediate, becomes a waste, it must be managed according to Federal and/or

State hazardous waste regulations. Also defined as a hazardous waste is any residue, contaminated soil, water, or other debris resulting from the cleanup of a spill, into water or on dry land, of this waste. Generators of small quantities of this waste may qualify for partial exclusion from hazardous waste regulations (40 CFR 261.5).
[40 CFR 261.33 (7/1/97)]**PEER REVIEWED**

F003; When **ethyl acetate** is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F003), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/97)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. **Ethyl acetate** is produced, as an intermediate or final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/97)]**PEER REVIEWED**

FDA Requirements:

Certification of this color additive when used as a diluent (in inks for marking fruit & vegetables) is not necessary for the protection of the public health and therefore batches thereof are exempt from the requirements of section 706(c) of the Federal Food, Drug, and Cosmetic Act. /Restrictions incl no residue./
[21 CFR 73.1 (4/1/97)]**PEER REVIEWED**

Synthetic flavoring substances and adjuvants /for human consumption/ that are generally recognized as safe for their intended use, within the meaning of section 409 of the Act. **Ethyl acetate** is included on this list.

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Number. ... Isolate spill or leak area immediately for at least 50 to lOO meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs

Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, isolate for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. ... Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the

material(s) involved, and take precautions to protect themselves.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Prior History of Accidents:

The wreck of the MV Ariadne, a Panamanian flag container ship, is examined as a case study of a hazardous substance emergency response in a third world country. /The ship/, carrying a cargo of heavy fuel oil, tetraethyl lead, xylene, toluene, methyl isobutyl ketone, butyl acetate, **ethyl acetate,** and acetone was grounded while departing the harbor of Mogadishu, Somalia. The Somalian government requested a team of technical advisors to help respond appropriately to the emergency. The major issues addressed by the advisory team were the need for additional salvage equipment and expertise, the danger of toxic fumes from the fire and explosions aboard the ship, the presence and possible release of tetraethyl lead, possible port blockage by the wreck, recovery of the chemical drums, and the extent of environmental damage caused by the release of oil, pesticides, and tetraethyl lead into the harbor. ...

Employees should wash promptly when skin is wet or contaminated. Remove clothing immediately if wet or contaminated to avoid flammability hazard.
[Sittig, M. Handbook of Toxic and Hazardous Chemicals and Carcinogens, 1985. 2nd ed. Park Ridge, NJ: Noyes Data Corporation, 1985. 409]**PEER REVIEWED**

Avoid breathing vapors. Keep upwind. Wear appropriate chemical protective gloves, boots and goggles. Do not handle broken packages unless wearing appropriate personal protective equipment. Wash away any material which may have contacted the body with copious amounts of water or soap and water.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 439]**PEER REVIEWED**

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to disperse vapors and dilute standing pools of liquid.
[Association of American Railroads. Emergency Handling of Hazardous Materials in Surface Transportation. Washington, DC: Association of American Railroads, Bureau of Explosives, 1994. 439]**PEER REVIEWED**

SRP: Contaminated protective clothing should be segregated in such a manner so that there is no direct

personal contact by personnel who handle, dispose, or clean the clothing. Quality assurance to ascertain the completeness of the cleaning procedures should be implemented before the decontaminated protective clothing is returned for reuse by the workers. Contaminated clothing should not be taken home at end of shift, but should remain at employee's place of work for cleaning.
PEER REVIEWED

The worker should immediately wash the skin when it becomes contaminated.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

Work clothing that becomes wet should be immediately removed due to its flammability hazard.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

An analysis of breakthrough times of low boiling organic solvent vapors in a commercial respirator cartridge under steady state and pulsating flow conditions was performed. A KGC-8 respirator cartridge packed with 22.5 grams of activated charcoal was exposed to 0, 100, 300, or 900 ppm carbon-tetrachloride, **ethyl-acetate,** methyl-acetate, acetone, or dichloromethane vapor under steady state or pulsed flow conditions in custom built apparatus. The steady state flow condition was achieved by setting the respirator cartridge in its holder and passing each solvent vapor through it at a flow rate of 30 liter per minute (l/min). The pulsating flow condition was achieved placing the respirator cartridge in a Tedler bag, expanding the bag by introducing each test vapor, and 'inhaling' the test vapor through the respirator cartridge using a breathing machine drawing 1.5 liters air per cycle at the rate 20 cycles/min. The total flow rate was adjusted to be similar to the 301/min rate utilized the steady state flow experiments. Solvent vapor concentrations were measured upstream and downstream from the cartridge by gas chromatography. Breakthrough times were determined as the time required for the solvent vapor concentrations downstream from the cartridge to increase to 5 ppm. The data were analyzed by logistic regression techniques. After converting the data to logarithms, the breakthrough times of all five solvents were linearly, inversely proportional to their initial concentrations under both steady state and pulsed flow conditions. The slopes of the lines were smaller for the solvents with the lower boiling points. The ratios of the breakthrough times measured under the pulsating flow to the steady slate flow condition (B/A ratio) varied from 0.77 to 0.71 for dichloromethane. The B/A ratios for the lOO ppm initial concentrations of the other four solvents varied only from 0.95 to 1.01. This indicated that except in the case of dichloromethane, there are no large differences in breakthrough tire under the two different flow conditions at lOO ppm. At the other concentrations, in each experiment as the concentration of the test vapor increased the breakthrough times under the pulsating flow condition became shorter compared to the steady state flow condition. /It was/ concluded that breakthrough of low boiling solvent vapors in respirator cartridges occurs earlier under pulsating flow than under steady state conditions.

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

If material not on fire and not involved in fire: Keep sparks, flames and other sources of ignition away. Keep material out of water sources and sewers. Build dikes to contain flow as necessary. Attempt to stop leak if without undue personnel hazard. Use water spray to disperse vapors and dilute standing pools of liquid.

Work clothing that becomes wet should be immediately removed due to its flammability hazard.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 131]**QC REVIEWED**

An analysis of breakthrough times of low boiling organic solvent vapors in a commercial respirator cartridge under steady state and pulsating flow conditions was performed. A KGC-8 respirator cartridge packed with 22.5 grams of activated charcoal was exposed to 0, 100, 300, or 900 ppm carbon-tetrachloride, **ethyl-acetate,** methyl-acetate, acetone, or dichloromethane vapor under steady state or pulsed flow conditions in custom built apparatus. The steady state flow condition was achieved by setting the respirator cartridge in its holder and passing each solvent vapor through it at a flow rate of 30 liter per minute (l/min). The pulsating flow condition was achieved placing the respirator cartridge in a Tedler bag, expanding the bag by introducing each test vapor, and 'inhaling' the test vapor through the respirator cartridge using a breathing machine drawing 1.5 liters air per cycle at the rate 20 cycles/min. The total flow rate was adjusted to be similar to the 301/min rate utilized the steady state flow experiments. Solvent vapor concentrations were measured upstream and downstream from the cartridge by gas chromatography. Breakthrough times were determined as the time required for the solvent vapor concentrations downstream from the cartridge to increase to 5 ppm. The data were analyzed by logistic regression techniques. After converting the data to logarithms, the breakthrough times of all five solvents were linearly, inversely proportional to their initial concentrations under both steady state and pulsed flow conditions. The slopes of the lines were smaller for the solvents with the lower boiling points. The ratios of the breakthrough times measured under the pulsating flow to the steady slate flow condition (B/A ratio) varied from 0.77 to 0.71 for dichloromethane. The B/A ratios for the lOO ppm initial concentrations of the other four solvents varied only from 0.95 to 1.01. This indicated that except in the case of dichloromethane, there are no large differences in breakthrough tire under the two different flow conditions at lOO ppm. At the other concentrations, in each experiment as the concentration of the test vapor increased the breakthrough times under the pulsating flow condition became shorter compared to the steady state flow condition. /It was/ concluded that breakthrough of low boiling solvent vapors in respirator cartridges occurs earlier under pulsating flow than under steady state conditions.

ETHYL ACETATE

CASRN: 141-78-6

For other data, click on the Table of Contents

Methods of Manufacturing:

Co-product of butane oxidation to acetic acid at 175 deg C and 50 atm in the presence of catalytic cobalt and chromium ions; co-product of the ethanolysis of polyvinyl acetate to polyvinyl alcohol.
[CHEMICAL PRODUCTS SYNOPSIS: Ethyl Acetate (1983)]**PEER REVIEWED**

Acetaldehyde (Tishchenko reaction); ethanol + acetic acid (esterification); polyvinyl acetate + ethanol (transesterification; byproduct of polyvinyl alcohol reaction).
[Ashford, R.D. Ashford's Dictionary of Industrial Chemicals. London, England: Wavelength Publications Ltd., 1994. 387]**PEER REVIEWED**

By heating acetic acid and ethyl alcohol in presence of sulfuric acid and distilling.
[Lewis, R.J., Sr (Ed.). Hawley's Condensed Chemical Dictionary. 12th ed. New York, NY: Van Nostrand Rheinhold Co., 1993 477]**PEER REVIEWED**

Laboratory Methods:

Clinical Laboratory Methods:

WHEN GAS CHROMATOGRAPHIC-MASS SPECTROSCOPY WAS USED IN ANALYSIS, **ETHYL ACETATE** WAS DETECTED IN ALL BLOOD SAMPLES & BRAIN TISSUES. THE CURVES OF BLOOD ETHYL ALCOHOL CONCN VS BLOOD PH VALUES SHOWED A REGRESSION DISTRIBUTION PATTERN. THESE RESULTS MAY BE USED IN FORENSIC INVESTIGATIONS.
[KOJIMA T ET AL; NIPPON HOIGAKU ZASSHI 34 (5): 587-95 (1980)]**PEER REVIEWED**

DETECTION & IDENTIFICATION OF VOLATILE ORGANIC COMPOUNDS, INCLUDING **ETHYL ACETATE,** IN WHOLE BLOOD, PLASMA, OR SERUM BY HEADSPACE GAS CHROMATOGRAPHY AS AN AID TO THE DIAGNOSIS OF SOLVENT ABUSE.
[RAMSEY JD, FLANAGAN RJ; J CHROMATOGR 240 (2): 423-44 (1982)]**PEER REVIEWED**

Analytic Laboratory Methods:

ANALYTE: **ETHYL ACETATE.** MATRIX: AIR. PROCEDURE: ADSORPTION ON CHARCOAL, DESORPTION WITH CARBON DISULFIDE, GAS CHROMATOGRAPHY. RANGE: 704-2950 MG/CU M.
[U.S. Department of Health, Education Welfare, Public Health Service. Center for Disease Control, National Institute for Occupational Safety Health. NIOSH Manual ofAnalytical Methods. 2nd ed. Volumes 1-7. Washington, DC: U.S. Government Printing Office, 1977-present.,p. V2 S49]**PEER REVIEWED**

Residual solvents in pharmaceutical powders were determined by gas chromatography with a headspace injection system. The chromatography conditions and parameters of the injection system were optimized to enable the quantification by external standardization of 21 most common solvents in concn ranging from a few ppm to a few percent. Porapak Q (100-120 mesh) was used as the stationary phase with flame ionization detection.
[Guimbard JP et al; J chromatogr 403: 109-21 (1987)]**PEER REVIEWED**

A generalized GC method is described for the determinations of a wide variety of residual solvents and other volatile impurities in bulk pharmaceuticals. ... Analytical data from replicated determinations of 7 representative cmpd are reported.
[Haky JE, Stickney TM; J Chromatogr 321 (1): 137-44 (1985)]**PEER REVIEWED**

The head space method for determining volatile gases was developed and compared with results obtained by the conventional purge and trap method. A gas chromatogram fitted with a retractable retrofit on

column injectors and split inlet systems was used. The more highly volatile compounds /including **ethyl acetate/** were clearly evident by the method but were lost to breakthrough in the purge and trap method. Head space samples generated contained appreciable amounts of water and were dominated by lower molecular weight compounds under normal conditions.
[Takeoka G, Jennings W; J Chromatrogr Sci 22 (5): 177-84 (1984)]**PEER REVIEWED**

Esters in distilled liquors, spectrophotometric method. Esters including **ethyl acetate** react quantitatively with hydroxylamine in alkaline solutions to form a hydroxamic acid which, forms colored complex with ferric ions. Ester concentration is proportional to absorbance at 525 nm at constant alcohol concentration and is calculated from standard curves.
[Association of Official Analytic Chemists. Official Methods of Analysis of the AOAC. 14th ed. Arlington, VA: Association of Official Analytic Chemists, Inc., 1984. 182]**PEER REVIEWED**

NIOSH Method 1457. Determination of **Ethyl Acetate** by Gas Chromatography with Flame Ionization Detection, GC/FID, workplace air, detection limit, 0.050 mg/cu m.
[U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSH Manual of Analytical Methods. 4th ed.Methods A-Z & Supplements. Washington, DC: U.S. Government Printing Office, Aug 1994.]**PEER REVIEWED**

AOAC Method 972.10. Alcohols (Higher) and **Ethyl Acetate** in Distilled Liquors. Alternative Gas Chromatographic Method.

Metabolism/Metabolites:

The purpose of this study was to clarify whether the blood concentration of inhaled toluene, ethylbenzene, m-xylene, or mesitylene can change after the concomitant pulmonary absorption of **ethyl acetate. (**Adult female Sprague-Dawley rats were exposed in a 20 liter glass chamber under dynamic conditions for 2 hours to various concentrations of the aromatics without or in combination with different concentrations of **ethyl acetate (**0, 1000, or 4000 ppm) in air. Concentration ranges were as follows: toluene, 140-690 ppm; ethylbenzene, 120-650 ppm; m-xylene, 100-560 ppm; mesitylene, 120-720 ppm; and **ethyl acetate,** 1000 or 4000 ppm. The coexposures with **ethyl acetate** lowered the blood concentrations of other inhaled aromatics. This reduction was statistically significant following a 2 hour exposure to 230 ppm toluene in combination with 1000 ppm **ethyl acetate,** 650 ppm ethylbenzene with 1000 ppm **ethyl acetate,** and 100 ppm m-xylene with 4000 ppm **ethyl acetate.)** Similarly a significant reduction of the blood level of the aromatics by **ethyl acetate** coinhalation was also observed at higher exposure concentrations with toluene and m-xylene. A metabolic interaction such as enhanced disposition of the aromatics, may be responsible for these effects. However, it is possible that the solubility of the solvents could be altered by the presence of **ethyl acetate.** It was concluded that coexposures to concentrations in the order of the threshold limit values (100 ppm for these solvents) with 400 ppm **ethyl acetate** should not be followed by a dangerous change of the blood levels of the aromatics.

Human Health Effects:

Toxicity Summary:

The acute toxicity of ethylbenzene to algae, aquatic invertebrates and fish is moderate. ... No information is available regarding chronic exposure of aquatic organisms to ethylbenzene. There is limited information regarding the toxicity of ethylbenzene to bacteria ... There are no data for terrestrial plants, birds, or wild mammals. Human exposure to ethylbenzene occurs mainly by inhalation; 40-60% of inhaled ethylbenzene is retained in the lung. Ethylbenzene is extensively metabolized, mainly to mandelic and phenylglyoxylic acids. These urinary metabolites can be used to monitor human exposures. Ethylbenzene has low acute and chronic toxicity for both animals and humans. It is toxic to the central nervous system and is an irritant of mucous membranes and the eyes. ... Ethylbenzene is an inducer of liver microsomal enzymes. It is not mutagenic or teratogenic ... No information is available on reproductive toxicity or carcinogenicity of ethylbenzene. A guidance value of 22 mg/ cu m (5 ppm) has been calculated from animal studies. /This value would correspond to a weekly absorbed dose (daily ventilation of 20 cu m with 60% retention) of about 2000 mg./ The estimated exposure of the general population (even in the worst case situation) is below this guidance value. Long term occupational exposure to ethylbenzene concentrations estimated to be of this order of magnitude did not cause adverse health effects in workers.

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 80,726 workers (21,785 of these are female) are potentially exposed to ethylbenzene in the US(1). Occupational exposure to ethylbenzene may occur via inhalation at municipal waste composting facilities where the air concn was found to be 78,000-178,000 ug/cu m(2),and through inhalation and dermal contact with this compound at worplaces where ethylbenzene is produced or used(SRC). The general population may be exposed to ethylbenzene via inhalation of ambient air, ingestion of foods and fish, and drinking contaminated water, and dermal contact with this compound and other products such as gasoline which contains ethylbenzene(SRC).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983) (2) Eitzer BD; Environ Sci Technol 29: 896-902 (1995)]**PEER REVIEWED**

Body Burden:

Ethylbenzene was detected, not quantified, in 8 of 8 samples of mother's milk from 4 US urban areas(1). 16.5% of 387 expired air samples taken from 54 normal, healthy, urban volunteers were positive for ethylbenzene concn with an avg of 1.8 ng/l expired air(2). Whole blood samples from 250 subjects ranged in ethylbenzene concns from not detected to 59 ppb, with an avg of 1.0 ppb(3).
[(1) Pellizzari ED et al; Bull Environ Contam Toxicol 28: 322-8 (1982) (2) Krotoszynski BK et al; J Anal Toxicol 3: 225-34 (1979) (3) Antoine SR et al; Bull Environ Contam Toxicol 36: 364-71 (1986)]**PEER REVIEWED**

Average Daily Intake:

AIR INTAKE: (assume air concn of 0.2-2.7 ppb)(2-6); 17-235 ug; WATER INTAKE: (assume water concn of 0-4 ppb(1)) 0-8 ug; FOOD INTAKE: insufficient data(SRC).

The following Overview, *** ETHYLBENZENE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- Ethylbenzene is an eye, skin, and mucous membrane irritant. Narcosis may also occur.
- Exposure to ethylbenzene at significant concentrations may cause profuse lacrimation, conjunctivitis, nasal and respiratory tract irritation, chest constriction, vertigo, headache, irritability, and possibly functional nervous system disturbances at high concentrations.
- Chronic exposure in humans may caused fatigue, sleepiness, headache, and irritation of the eyes and respiratory tract.
- In experimental animals, exposure to ethylbenzene may cause eye, skin, and mucous membrane irritation; changes in liver and kidney weights; CNS depression; pulmonary edema; and respiratory failure.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Ethylbenzene can be an eye irritant.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Ethyl benzene is a respiratory tract irritant and is a pulmonary aspiration hazard following large ingestions. In fatal cases, pulmonary edema had developed; death occurs in respiratory failure. However, human studies demonstrated no signs or symptoms of respiratory tract irritation at 85 and 100 ppm.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Ethyl benzene has CNS depressant (narcotic) properties

at high concentrations.
- CNS symptoms may include headache, nausea, weakness, incoordination, dizziness, sleepiness, loss of coordination, judgement, and consciousness, and coma or death may occur with significant exposure. Cerebral edema may occur in fatal poisonings.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Ethyl benzene is a pulmonary aspiration hazard following ingestion, and is toxic with ingestion exposure. Ingestion would be predicted to cause GI tract irritation or burns.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Slight changes in the liver occurred in rats exposed to 600 ppm for up to 16 weeks.

GENITOURINARY

0.2.10.1 ACUTE EXPOSURE

- Slight changes in the kidneys occurred in rats exposed to 600 ppm for up to 16 weeks.

HEMATOLOGIC

0.2.13.1 ACUTE EXPOSURE

- Ethyl benzene has been shown NOT to have the myelotoxic activity associated with BENZENE.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Dermal contact causes inflammation and erythema. Ethyl benzene can be absorbed through intact skin.

REPRODUCTIVE HAZARDS

- Ethyl benzene is teratogenic and fetotoxic in experimental animals, and has been detected in umbilical cord blood.

Laboratory:

- Urinary levels of mandelic acid can be used as an indicator of exposure to ethylbenzene.

Treatment Overview:

SUMMARY EXPOSURE

- FIRST AID (NIOSH, 2000) -
  1. EYE EXPOSURE - Immediately wash the eyes with large amounts of water, occasionally lifting the lower and upper lids. Get medical attention immediately. Contact lenses should not be worn when working with this chemical.
  2. DERMAL EXPOSURE - Flush the contaminated skin with water promptly. If this chemical penetrates the clothing, immediately remove the clothing and flush the skin with water promptly. If irritation persists after washing, get medical attention.
  3. INHALATION EXPOSURE - Move the exposed person to fresh air at once. If breathing has stopped, perform mouth-to-mouth resuscitation. Keep the affected person warm and at rest. Get medical attention as soon as possible.
  4. ORAL EXPOSURE - If this chemical has been swallowed, get medical attention immediately.
  5. TARGET ORGANS - Eyes, skin, respiratory tract, and central nervous system.
- GENERAL -
  1. Move victims of inhalation exposure from the toxic environment and administer 100% humidified supplemental oxygen with assisted ventilation as required. Exposed skin and eyes should be copiously flushed with water. Because of the potential for rapid onset of CNS depression or seizures with possible aspiration of gastric contents, EMESIS SHOULD NOT BE INDUCED. Cautious gastric lavage followed by administration of activated charcoal may be of benefit if the patient is seen soon after the exposure.
- INHALATION EXPOSURE -
  1. DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
  2. If bronchospasm and wheezing occur, consider treatment with inhaled sympathomimetic agents.
  3. PULMONARY EDEMA (NONCARDIOGENIC): Maintain ventilation and oxygenation and evaluate with frequent arterial blood gas or pulse oximetry monitoring. Early use of

PEEP and mechanical ventilation may be needed.

- DERMAL EXPOSURE -
  1. DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
  2. Treat dermal irritation or burns with standard topical therapy. Patients developing dermal hypersensitivity reactions may require treatment with systemic or topical corticosteroids or antihistamines.
  3. Some chemicals can produce systemic poisoning by absorption through intact skin. Carefully observe patients with dermal exposure for the development of any systemic signs or symptoms and administer symptomatic treatment as necessary.
- EYE EXPOSURE -
  1. DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.
- ORAL EXPOSURE -
  1. Because of the potential for CNS depression or gastrointestinal tract irritation, do not induce emesis.
  2. Weigh the potential toxicity of the amount of ethylbenzene ingested against the substantial risk of pulmonary aspiration of gastric contents. Ethylbenzene may "wick" up around a lavage tube, allowing pulmonary aspiration.
     a. Significant esophageal or gastrointestinal tract irritation or burns may occur following ingestion. The possible benefit of early removal of some ingested material by cautious gastric lavage must be weighed against potential complications of bleeding or perforation.
  3. GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
     a. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation;

and trivial or non-toxic ingestion.

4. ACTIVATED CHARCOAL/CATHARTIC: Administer charcoal slurry, aqueous or mixed with saline cathartic or sorbitol. The FDA suggests 240 mL of diluent/30 g of charcoal. Usual charcoal dose is 25 to 100 grams in adults and adolescents, 25 to 50 grams in children (1 to 12 years old), and 1 gram/kilogram in infants less than 1 year old.
   a. Routine use of cathartics is NOT recommended. If used, administer only ONE dose of cathartic. Administer one dose of a cathartic, mixed with charcoal or given separately. See "Treatment: Prevention of Absorption" in the main document.
5. Observe patients with ingestion carefully for the possible development of esophageal or gastrointestinal tract irritation or burns. If signs or symptoms of esophageal irritation or burns are present, consider endoscopy to determine the extent of injury.

ORAL EXPOSURE

- Because of the potential for CNS depression or gastrointestinal tract irritation, Do NOT induce emesis.
- Weigh the potential toxicity of the amount of ethylbenzene ingested against the substantial risk of aspiration. Ethylbenzene may "wick" up around a lavage tube, allowing pulmonary aspiration.
  1. Significant esophageal or gastrointestinal tract irritation or burns may occur following ingestion. The possible benefit of early removal of some ingested material by cautious gastric lavage must be weighed against potential complications of bleeding or perforation.
- GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
  1. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.
- ACTIVATED CHARCOAL/CATHARTIC: Administer charcoal slurry, aqueous or mixed with saline cathartic or sorbitol. The FDA suggests 240 mL of diluent/30 g of

charcoal. Usual charcoal dose is 25 to 100 grams in adults and adolescents, 25 to 50 grams in children (1 to 12 years old), and 1 gram/kilogram in infants less than 1 year old.

1. Routine use of cathartics is NOT recommended. If used, administer only ONE dose of cathartic. Administer one dose of a cathartic, mixed with charcoal or given separately. See "Treatment: Prevention of Absorption" in the main document.

- Observe patients with ingestion carefully for the possible development of esophageal or gastrointestinal tract irritation or burns. If signs or symptoms of esophageal irritation or burns are present, consider endoscopy to determine the extent of injury.

INHALATION EXPOSURE

- DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
- If bronchospasm and wheezing occur, consider treatment with inhaled sympathomimetic agents.
- PULMONARY EDEMA (NONCARDIOGENIC): Maintain ventilation and oxygenation and evaluate with frequent arterial blood gas or pulse oximetry monitoring. Early use of PEEP and mechanical ventilation may be needed.

EYE EXPOSURE

- DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.

DERMAL EXPOSURE

- DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
- Treat dermal irritation or burns with standard topical therapy. Patients developing dermal hypersensitivity reactions may require treatment with systemic or topical corticosteroids or antihistamines.
- Some chemicals can produce systemic poisoning by absorption through intact skin. Carefully observe patients with dermal exposure for the development of any systemic signs or symptoms and administer symptomatic treatment as necessary.

Animal Toxicity Studies:

Toxicity Summary:

The acute toxicity of ethylbenzene to algae, aquatic invertebrates and fish is moderate. ... No information is available regarding chronic exposure of aquatic organisms to ethylbenzene. There is limited information regarding the toxicity of ethylbenzene to bacteria ... There are no data for terrestrial plants, birds, or wild mammals. Human exposure to ethylbenzene occurs mainly by inhalation; 40-60% of inhaled ethylbenzene is retained in the lung. Ethylbenzene is extensively metabolized, mainly to mandelic and phenylglyoxylic acids. These urinary metabolites can be used to monitor human exposures. Ethylbenzene has low acute and chronic toxicity for both animals and humans. It is toxic to the central nervous system and is an irritant of mucous membranes and the eyes. ... Ethylbenzene is an inducer of liver microsomal enzymes. It is not mutagenic or teratogenic ... No information is available on reproductive toxicity or carcinogenicity of ethylbenzene. A guidance value of 22 mg/ cu m (5 ppm) has been calculated from animal studies. /This value would correspond to a weekly absorbed dose (daily ventilation of 20 cu m with 60% retention) of about 2000 mg./ The estimated exposure of the general

population (even in the worst case situation) is below this guidance value. Long term occupational exposure to ethylbenzene concentrations estimated to be of this order of magnitude did not cause adverse health effects in workers.

Mice, B6C3F1 Fischer-344 rats, and /rabbits /New Zealand/ (five/sex/group) were exposed by inhalation to ethylbenzene vapors for 6 hr/day, 5 days/week for 4 weeks (20 exposures). Rats and mice received 0, 99, 382, or 782 ppm ethylbenzene while rabbits received 0, 382, 782, or 1610 ppm. No changes were evident in mortality patterns, clinical chemistries, urinalyses, or treatment-related gross/microscopic (including ophthalmologic) lesions. Rats exhibited sporadic lacrimation and salivation, as well as significantly increased liver weights at 382 and 782 ppm, and small increases in leukocyte counts at 782 ppm. Males at this exposure level also showed marginal elevations in platelet counts. In mice, females showed statistically increased absolute and relative liver weights at 382 and 782 ppm while males had statistically increased relative liver-to-brain weight ratios only at 782 ppm. Female rabbits at the high exposure level of 1610 ppm gained weight more slowly than controls (not statistically significant); males showed a similar transient downward trend after 1 week, but showed no differences from controls at study's end. A no observed adverse effect level (NOAEL) of 382 ppm appears appropriate for rats and mice with a lowest observed adverse effect level (LOAEL) of 782 ppm. A NOAEL of 782 ppm and LOAEL of 1610 ppm are appropriate for rabbits.

TSCA Test Submissions:

In a single generation reproduction study, 380 female and 60 male Wistar rats were exposed to ethylbenzene at average daily concentrations of 97 or 959 ppm 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily on gestation days (GD) 1-19 at concentrations of 96 (low) or 985 (high) ppm. Animals were sacrificed and examined on GD 21. No significant differences were observed between treatment groups and controls in food consumption, gestational body weights (of pregnant rats), organ weights (of male rats), histopathology of liver, kidney or lungs, percent pregnancy, no. of corpora lutea, no. of implants, total live or dead fetuses, no. of live or dead fetuses per litter, no. of resorptions per litter and percent litters with resorptions. A significant difference (ANOVA, Duncan's multiple range test) was observed in pregestational body weights in both treatment groups. Maternal toxicity was indicated in the high dose groups (dosed at the high level during both periods or dosed with air during pregestational and with the high level during gestation) by significant differences (ANOVA, Duncan's multiple range test) in liver, spleen and kidney weights. Statistically significant differences were seen in mean crown-rump length (in the group which was dosed at the high level during both periods), supernumerary ribs (in the 2 high dose groups and the group which was dosed with air pregestationally and with the low level during gestation) and rudimentary rib incidence (in the group dosed with air during pregestation and with the high level during gestation).
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150] **UNREVIEWED**

In a single generation reproduction study 96 New Zealand White rabbits were artifically inseminated and exposed to ethylbenzene at average daily concentrations of 99 or 962 ppm 7 hours per day, through gestation day (GD) 24. Animals were sacrificed and examined on GD 30. Mortality was observed in 2 does, 1 from each dose group. No significant differences were observed between treatment groups and controls in the following: food consumption; body weight; weight gain; lung, kidney, and spleen mean weights; histopathology of liver, kidney, or lungs; percent pregnancy; no. of corpora lutea; no. of implants; total live or dead fetuses; no. of dead fetuses per litter; no. of resorptions per litter; percent litters with resorptions; and skeletal, visceral, or external parameters in fetuses. Significant differences (ANOVA, Duncan's multiple range test) relative to controls were observed in liver weights of the high dose group and in mean number of live fetuses per litter in both treatment groups.
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150]

UNREVIEWED

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 89, 77, and 77 female Wistar rats exposed to 0, 100, and 1000 ppm of the test material respectively by inhalation for 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily through the 19th day of gestation. The rats were killed and examined at the 21st day of gestation. No significant differences were observed in food consumption and body weights during progestational and gestational exposure periods. At 1000 ppm relative and absolute liver, spleen, and kidney weights were significantly greater than controls and or the 100 ppm group. No treatment-related histological changes were observed. Body weights, placenta weights, and sex ratios were all within normal limits. There were no significant increases in major malformations or minor anomalies. Litters were examined for the presence of external, visceral, and skeletal defects as well as the incidence of growth retardation and intrauterine mortality. A statistically significant increased incidence of fetal supernumary ribs was observed at the 1000 ppm exposure. It was concluded that ethylbenzene caused maternal and developmental toxicity (significant increase in extra ribs) at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167] **UNREVIEWED**

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 24, 23, and 22 New Zealand white rabbits artificially inseminated and exposed for 7 hours daily to 0, 100, and 1000 ppm of the test material respectively until the 24th day of gestation. Neither maternal toxicity nor embryotoxicity was observed in rabbits exposed to ethylbenzene at 100 or 1000 ppm. Rabbits had increased maternal liver weights at 1000 ppm and reduced mean number of live fetuses at 100 and 1000 ppm. No significant differences were observed in food consumption and weight gain. No treatment-related organ weight or histopathological changes were observed. Fetal size (weight and length), placenta weights, and sex ratios were all within normal limits. The sex ratios of the groups were not affected by treatment. No statistically significant incidences of major malformations, minor anomalies, or common variants were observed. It was concluded that the test material did not induce significant maternal toxicity, embryomortality, growth retardation, or teratogenicity at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167] **UNREVIEWED**

The frequency of chromosomal aberrations was evaluated in vitro by exposing rats liver (RL1) cells to 25, 50 or 100 ug of ethyl benzene/ml. No increases in the frequency of chromatid gaps, chromatid breaks or total chromosome aberrations was observed at any dose level. Ethyl benzene did not induce chromosome damage in this assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The mutagenicity of ethyl benzene was evaluated in E. coli tester strains WP2 and WP2uvrA and in Salmonella tester strains TA98, TA100, TA1535, TA1537, and TA1538 (Ames test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of preliminary bacterial toxicity determinations, ethyl benzene, in DMSO, was tested for mutagenicity at concentrations of 0.2, 2.0, 20.0, 200.0, and 2000.0 ug/plate using the direct plate

incorporation method. Ethyl benzene did not cause a positive response in any of the tester strains with or without metabolic activation.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The ability of ethyl benzene to induce conversion of differentially inactive alleles to wild-type alleles in Saccharomyces cervisiae was examined in the mitotic gene conversion assay. The cultures were dosed with solutions of 20 ul (in the absence of added metabolic action provided by Aroclor-induced rat liver S9 fraction) or 25 ul (with S9) of 1, 10, 50, 100 or 500 mg ethyl benzene/ml. Ethyl benzene did not produce an increase mitotic gene conversion, either with or without added metabolic activation, and was not considered to be mutagenic in the assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1343]**PEER REVIEWED**

After 2 volunteers were exposed to 65 ppm ethylbenzene for 3 hr, the metabolites of ethylbenzene in their urine, mandelic acid, hippuric acid (HA), and phenylglyoxylic (PhGA) were analyzed. The metabolites were excreted in the urine in the order mandelic acid > hippuric acid > phenylglyoxylic. The highest value of excretion was observed 6-10 hr after the beginning of exposure. Mandelic acid/phenylglyoxylic and hippuric/phenylglyoxylic mol ratios of total excretion in urine were 3.5 and 2.6 respectively.
[Yamasaki Y; Okayama Igakkai Zasshi 96 (5/6): 531-5 (1984)]**PEER REVIEWED**

The purpose of this study was to clarify whether the blood concentration of inhaled toluene, ethylbenzene, m-xylene, or mesitylene can change after the concomitant pulmonary absorption of **ethyl acetate. (**Adult female Sprague-Dawley rats were exposed in a 20 liter glass chamber under dynamic conditions for 2 hours to various concentrations of the aromatics without or in combination with different concentrations of **ethyl acetate (**0, 1000, or 4000 ppm) in air. Concentration ranges were as follows: toluene, 140-690 ppm; ethylbenzene, 120-650 ppm; m-xylene, 100-560 ppm; mesitylene, 120-720 ppm; and **ethyl acetate,** 1000 or 4000 ppm. The coexposures with **ethyl acetate** lowered the blood concentrations of other inhaled aromatics. This reduction was statistically significant following a 2 hour exposure to 230 ppm toluene in combination with 1000 ppm **ethyl acetate,** 650 ppm ethylbenzene with 1000 ppm **ethyl acetate,** and 100 ppm m-xylene with 4000 ppm **ethyl acetate.)** Similarly a significant reduction of the blood level of the aromatics by **ethyl acetate** coinhalation was also observed at higher exposure concentrations with toluene and m-xylene. A metabolic interaction such as enhanced disposition of the aromatics, may be responsible for these effects. However, it is possible that the solubility of the solvents could be altered by the presence of **ethyl acetate.** It was concluded that coexposures to concentrations in the order of the threshold limit values (100 ppm for these solvents) with 400 ppm **ethyl acetate** should not be followed by a dangerous change of the blood levels of the aromatics.
[Freundt KJ et al; Bull Environ Contam Toxicol 42 (4): 495-8 (1989)]**PEER REVIEWED**

Stereochemical considerations in the metabolism of ethylbenzene and styrene were investigated. Three alternative methods used to determine the enantiomeric composition of mandelic-acid in urine arising from exposure to styrene or ethylbenzene were described. Of the methods described, the direct gas chromatographic resolution of the enantiomers on a chiral stationary phase was the best approach. It was a simple analytical technique which avoids complex derivatization. An additional advantage was that it may be used as a gas liquid chromatography/mass spectrometry method and thus has advantages of sensitivity and specificity. F-19 nuclear magnetic resonance proved a useful alternative technique and

was invaluable if standards of the pure isomers were not available. The major advantage of the nuclear magnetic resonance approach was that absolute configuration of the compound could be elucidated. (In experimental studies, rats were administered ethylbenzene or styrene at 100 mg/kg by the stomach tube; urine was collected over 96 hours. Male volunteers were exposed to ethylbenzene vapor in an exposure chamber at 435 mg/cu m for 4 hours; urine samples were collected before, during and after exposure. The results indicate that whereas only the R-enantiomer of mardelic acid was excreted after ethylbenzene exposure, the mandelic acid from styrene was essentially racemic. In three workers exposed occupationally to styrene, R/S ratios of 1.16, 1.27 and 1.14 were found. A synthetic R/S mixture of mandelic acid has a R/S ratio of 1.03.)

When administered sc to 40 rats (2.5 ml, 1:1 v/v), ethylbenzene was detected in the blood within 2 hours, and the levels of ethylbenzene (10-15 ppm in blood) were maintained for at least 16 hours.
[USEPA; Ambient Water Quality Criteria Doc: Ethylbenzene p.C-6 (1980) EPA 440/5-80-048]**PEER REVIEWED**

After exposure of rats to atmospheres of 50, 300, or 600 ppm ethylbenzene 6 hr/day, 5 days/wk, for maximum of 16 wk, the concn of ethylbenzene in perirenal fat and the urinary excretion of 1-phenylethanol, omega-hydroxyacetophenone, mandelic acid, phenylglyoxylic acid, hippuric acid, and phenaceturic acid were measured at the 2nd, 5th, and 9th weeks. Excretion of metabolites into urine increased in a dose-related manner, but less than linearly. The level of exposure, but not the duration of exposure, markedly affected the pattern of the metabolites in the urine. The concn of ethylbenzene in perirenal fat was low at 50 ppm, high at 300 ppm and higher still at 600 ppm, but not in proportion to the increased dose.
[Engstroem K et al; Xenobiotica 15 (4): 281-6 (1985)]**PEER REVIEWED**

Percutaneous absorption of benzene, toluene, ethylbenzene, and aniline was investigated in male HRS/J hairless mice. Stainless steel skin depots containing 100 to 150 mg of solid sorbent were fixed to the backs of anesthetized mice and charged with about 5 ul of (14)C tagged test solution. Expired air samples were obtained until 4 hours after exposure, when mice were killed and samples for radioactivity were obtained from the skin depot, the skin under the depot, a wiping of the skin under the depot, the carcass, feces, urine, and cage washings. Physical constants were determined for each test compound, including octanol/water partition coefficient, solubility, vapor pressure, melting and boiling points, and absorption and evaporation rates. Solvent recovery exceeded 90% in all mice with highest recovery in the skin depot. Average administered doses were 3.94 mg benzene, of which 0.99% was absorbed; 3.89 mg toluene (2.31% absorbed), 4.10 mg ethylbenzene (3.61% absorbed), and 4.68 mg aniline (4.76% absorbed). Excretion rate in expired air was fastest during the first 15 minutes of exposure except in mice treated with toluene or ethylbenzene, which demonstrated maximal excretion rate during the second 15 minutes after exposure. A two compartment model was suggested by the initial rapid and subsequent gradual decay of expired breath excretion. Vapor pressure and boiling point were significantly correlated with the applied radioactive dose absorbed. Absorption rates were found to be 56, 49, 37, and 2.3 ug per square centimeter per minute for benzene, toluene, ethylbenzene, and aniline, respectively.

Mechanism of Action:

The effect of styrene, toluene, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium

produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or toluene in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.
[Mickiewicz W, Rzeczycki W; Biochem Pharmacol 37 (23): 4439-44 (1988)]**PEER REVIEWED**

Effect of monocyclic aromatic hydrocarbons, their metabolites, and their structure on brain dopamine was studied. Adult male New Zealand rabbits were exposed to 750 ppm toluene, styrene, ethylbenzene, vinyltoluene, 7-methylstyrene, xylenes, and fresh air. Six groups of eight rabbits received 4 mM/kg ip for 3 days of hippuric acid, mandelic acid, methylhippuric acid, phenylglyoxylic acid, or 7-methylmandelic acid. Animals were killed 12 hours after inhalation exposure or 24 hours after the last dose of acid. The hypothalamus, striatum, hippocampus, tuberoinfundibular area, and part of the brain cortex were treated with 0.2 molar perchloric acid, homogenized, desorbed on alumina, and centrifuged. Supernatant was filtered and used to measure homovanillic acid. Styrene induced a marked dopamine depletion and a significant increase in homovanillic acid concentration. Ethylbenzene and vinyltoluene produced a smaller, but statistically significant effect. Toluene, xylenes, and 7-methylstyrene were ineffective. Phenylglyoxylic acid caused a decrease in dopamine levels and a consistent rise in homovanillic acid in striatal and tuberoinfundibular regions. Mandelic acid elicited the same effect, but to a lesser degree. 7-Methylmandelic, methylhippuric, and hippuric acids evoked no response. Neither solvents nor their metabolites affected norepinephrine contents of brain areas in which this neurotransmitter reaches high concentrations. It was concluded that the results indicate that the changes in brain dopamine depend on metabolic interferences of some metabolites of aromatic solvents with dopamine catabolism. Only metabolites whose side chain may be transformed into a alpha-keto acid caused dopamine depletion.
[Romanelli A et al; J Appl Toxicol 6 (6): 431-5 (1986)]**PEER REVIEWED**

The effect of organic solvents on the CNS was discussed. The similarity of effects of different solvents is believed to be due to the formation of tetrahydroisoquinolines by nonenzymatic condensation of dopamine with metabolites of organic solvents having a reactive carbonyl group. The suspected metabolites are phenylglyoxylic- acid that is formed by metabolism of ethylbenzene, styrene, vinyltoluene; trichloroacetaldehyde, which derives from trichloroethylene, tetrachloroethylene; and trichloroethane; glyoxylic acid that is synthesized from ethyleneglycol and ethyleneglycolmonomethyl ether; formaldehyde that is metabolized from methanol; and acetaldehyde that is transformed from ethanol. The tuberoinfundibular dopaminergic system may represent a target for metabolites dissolved in the blood stream. The suggested mechanism implies a selective vulnerability of pituitary functions. The impairment of tuberoinfundibular activity may explain most of the behavioral changes observed with styrene and perhaps with other similar solvents. It appears that the majority of pathways that are affected in the hypothalamic control of gonadotropins in primates are adrenergic and dopaminergic. Occupational

exposure to neurotoxins may cause repeated reversible CNS effects which are difficult to distinguish from the chronic effects. In workers exposed to styrene a relationship between recent exposure and measurable effects on CNS has been observed and prolonged exposure has failed to induce tolerance. It was concluded that although no excessive risk for Alzheimer disease and presenile dementia has been found, there is no indication that exposure to solvents does not cause irreversible or slowly reversible cognitive or neuropsychological impairment.
[Mutti A, Franchini I; Br J Ind Med 44 (11): 721-3 (1987)]**PEER REVIEWED**

Efforts were made to clarify the molecular basis of styrene toxicity on the dopaminergic systems and to evaluate whether the same mechanism was common to other solvents. Groups of male New Zealand rabbits were exposed to 750 ppm toluene, xylene, styrene, ethylbenzene, vinyltoluene, 7-methyl-styrene, or fresh air (control group). A significant depletion in both striatal and tubero infundibular dopamine was caused styrene, ethylbenzene, and vinyltoluene. Methylation of the aromatic ring of styrene did not change its activity, whereas methylation of the side chain drastically reduced its effect on dopamine. Treatments carried out with the main metabolites of aromatic solvents indicated that acidic metabolites of some solvents cause striatal and tubero infundibular dopamine depletion. Present data suggested a chemical reaction between dopamine and some acidic metabolites. The active metabolites have an alpha-keto acid as the side chain or as a part of their molecule. These keto acids condense nonenzymatically with dopamine in both experimental models and in occupational exposed workers as evidenced by the direct measurements of dopamine in the brain. According to the authors, such a mechanism may account for neurobehavioral effects resulting from solvent exposure such as mood changes, or impaired attention spans and decreasing psychomotor performance factors.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Ethylbenzene's production and use as an intermediate for the production of styrene, its presence in

automotive and aviation fuels, and its presence in crude oil may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 9.6 mm Hg at 25 deg C indicates ethylbenzene will exist solely as a vapor in the ambient atmosphere. Vapor-phase ethylbenzene will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 55 hr. If released to soil, ethylbenzene is expected to have moderate mobility based upon an estimated Koc of 520. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 7.88X10-3 atm-cu m/mole. Ethylbenzene may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation in soil takes place via nitrate-reducing processes. If released into water, ethylbenzene may adsorb to suspended solids and sediment in water based upon the estimated Koc. Biodegradation in a gasoline contaminated aquifer ranged from 10-16 days under aerobic conditions. Ethylbenzene was degraded in 8 days in groundwater and 10 days in seawater as a component of gas oil. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1.1 and 99 hrs, respectively. Measured BCFs of 0.67 to 15 suggest the potential for bioconcentration in aquatic organisms is low. Hydrolysis is not expected to occur due to the lack of hydrolyzable functional groups. Occupational exposure to ethylbenzene may occur through inhalation at municipal waste composting facilities and via inhalation and dermal contact with this compound at workplaces where ethylbenzene is produced or used. The general population may be exposed to ethylbenzene via inhalation of ambient air, drinking and eating contaminated foods and water, and by handling gasoline. Ethylbenzene is likely to be detected in groundwater. (SRC)
PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 80,726 workers (21,785 of these are female) are potentially exposed to ethylbenzene in the US(1). Occupational exposure to ethylbenzene may occur via inhalation at municipal waste composting facilities where the air concn was found to be 78,000-178,000 ug/cu m(2),and through inhalation and dermal contact with this compound at worplaces where ethylbenzene is produced or used(SRC). The general population may be exposed to ethylbenzene via inhalation of ambient air, ingestion of foods and fish, and drinking contaminated water, and dermal contact with this compound and other products such as gasoline which contains ethylbenzene(SRC).

Environmental Fate:

TERRESTRIAL FATE: Based on a classification scheme(1), an estimated Koc value of 520(SRC), determined from a structure estimation method(2), indicates that ethylbenzene is expected to have moderate mobility in soil(SRC). Volatilization of ethylbenzene from moist soil surfaces is expected to be an important fate process(SRC) given a Henry's Law constant of 7.88X10-3 atm-cu m/mole(3). The potential for volatilization of ethylbenzene from dry soil surfaces may exist(SRC) based upon a vapor pressure of 9.6 mm Hg(4). Ethylbenzene was completely degraded in microcosms inoculated with the sediment material from a refinery pond or activated sludge from the refinery treatment facility under nitrate-reducing conditions(5). At Sleeping Bear Dunes National Lakeshore in Michigan, ethylbenzene was degraded at slow rates via anaerobic degradation under ambient subsurface conditions using ferric

iron, sulfate and/or carbon dioxide as the terminal electron acceptors(6).

AQUATIC FATE: Based on a classification scheme(1), an estimated Koc value of 520(SRC), determined from an estimation method(2), indicates that ethylbenzene may adsorb to suspended solids and sediment(SRC). Volatilization from water surfaces is expected(3) based upon a Henry's Law constant of 7.88X10-3 atm-cu m/mole(4). Using this Henry's Law constant and an estimation method(3), volatilization half-lives for a model river and model lake are 1.1 and 99 hr, respectively(SRC). According to a classification scheme(5), an experimental log BCF of 1.19(7), which corresponds to a BCF of 15, suggests the potential for bioconcentration in aquatic organisms is low. In a shallow coastal plain aquifer contaminated with gasoline and diesel fuel in rural Sampson County in North Carolina, ethylbenzene was degraded in aerobic conditions within 10-16 days and in conditions of low initial oxygen, it was rapidly degraded in 21 days until the available oxygen was depleted(8). As a component of gas oil, ethylbenzene is completely degraded in groundwater in 8 days(9) and seawater in 10 days(10). In a mesocosm experiment using simulated Narragansett Bay conditions, complete biodegradation occurred in approximately 2 days after a 2 week lag in spring and a 2 day lag in summer(11).

ATMOSPHERIC FATE: According to a model of gas/particle partitioning of semivolatile organic compounds in the atmosphere(1), ethylbenzene, which has a vapor pressure of 9.6 mm Hg at 25 deg C(2), is expected to exist solely as a vapor. Vapor-phase ethylbenzene is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals(SRC); the half-life for this reaction in air is 55 hr(SRC), calculated from its rate constant of 7.1X10-12 cu cm/molecule-sec at 25 deg C(3).
[(1) Bidleman TF; Environ Sci Technol 22: 361-367 (1988) (2) Daubert TE et al; Physical & Thermodynamic Properties of Pure Chemicals NY, NY: Hemisphere Pub Corp (1989) (3) Atkinson R; J Phys Chem Ref Data Monograph No. 2 p. 48 (1994)]**PEER REVIEWED**

Environmental Biodegradation:

After a period of inocula adaptation, ethylbenzene is biodegraded fairly rapidly by sewage or activated sludge inoculua(1-3,9). As a component of gas oil, it is completely degraded in groundwater in 8 days(4) and seawater in 10 days(5). In a mesocosm experiment using simulated Narragansett Bay conditions, complete biodegradation occurred in approximately 2 days after a 2 week lag in spring and a 2 day lag in summer(6). Part of the attenuation in concn from a leaky gasoline storage tank in the chalk aquifer in England has been attributed to biodegradation(7). No degradation was observed in an anaerobic reactor even after 110 days acclimation(8) or at low concentrations in a batch reactor in 11 weeks under denitrifying conditions(10). Percent removal in an anaerobic, continuous-flow, laboratory bioflim column was 7% after a 2 day detention time(11); 99% removal was observed in a similar aerobic column following a 20 min detention time(11).

AEROBIC: A study was conducted using underground storage tanks containing gasoline and diesel fuel that contaminated a shallow coastal plain aquifer in rural Sampson County in North Carolina. Ethylbenzene was degraded in aerobic conditions within 10-16 days and in conditions of low initial oxygen, it was rapidly degraded in 21 days until the available oxygen was depleted(1). A combined culture experiment of Mycobacterium vaccae and Rhodococcus sp. strain R-22 showed M. vaccae alone and M. vaccae and R-22 together can oxidize ethylbenzene to 4-ethylphenol which is then degraded to 50 ppm within 72 hr(2).
[(1) Borden RC et al; Water Resour Res 33: 1105-15 (1996) (2) Fairlee JR et al; J Microbiol 43: 841-6 (1997)]**PEER REVIEWED**

ANAEROBIC: Anaerobic ethylbenzene transformation in Seal Beach Naval Weapons Station sediments in Southern California appeared to be strictly associated with nitrate-reducing processes(1). Ethylbenzene was completely degraded in microcosms inoculated with the sediment material from a refinery pond or activated sludge from the refinery treatment facility under nitrate-reducing conditions(2). At Sleeping Bear Dunes National Lakeshore in Michigan, ethylbenzene was degraded at slow rates via anaerobic degradation under ambient subsurface conditions using ferric iron, sulfate and/or carbon dioxide as the terminal electron acceptors(3).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of ethylbenzene with photochemically-produced hydroxyl radicals is 7.1X10-12 cu cm/molecule-sec at 298 K(1) which corresponds to an atmospheric half-life of about 55 hr at an atmospheric concn of 5X10+5 hydroxyl radicals per cu cm. Ethylbenzene is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(2). Ethylbenzene photolysis occurs via photooxidation hydrogen abstraction from the alkyl group by photooxydatively formed hydroxyl radical which results in the formation of acetophenone, and eventually benzaldehyde with 2-butanedial, 4-oxo-2-hexenal, and 2-ethyl-2-butenedial being suggested as further end products(3).
[(1) Atkinson R; J Phys Chem Ref Data Monograph No. 2 p. 48 (1994) (2) Lyman WJ et al; Handbook of Chemical Property Estimation Methods. Washington, DC: Amer Chem Soc pp. 7-4, 7-5 (1990) (3) Forstner HJL et al; Environ Sci Technol 31: 1345-58 (1997)]**PEER REVIEWED**

Environmental Bioconcentration:

Experimental data on the bioconcentration of ethylbenzene include a log BCF of 1.9 in goldfish(2) and a log BCF of 0.67 for clams exposed to the water-soluble fraction of crude oil(1). Experimentally, a log BCF of 1.19 has also been reported(4) which corresponds to a BCF of 15. According to a classification scheme(3), these BCFs suggest the potential for bioconcentration in aquatic organisms is low.
[(1) Nunes P, Benville PE Jr; Bull Environ Contam Toxicol 21: 719-24 (1979) (2) Ogata M et al; Bull Environ Contam Toxicol 33: 561-7 (1984) (3) Franke C et al; Chemosphere 29: 1501-14 (1994) (4) Park JH, Lee HJ; Chemosphere 26: 1905-16 (1993)]**PEER REVIEWED**

Soil Adsorption/Mobility:

Using a structure estimation method based on molecular connectivity indices(1), the Koc for ethylbenzene can be estimated to be 520(SRC). According to a classification scheme(2), this estimated Koc value suggests that ethylbenzene is expected to have low mobility in soil.
[(1) Meylan WM et al; Environ Sci Technol 26: 1560-67 (1992) (2) Swann RL et al; Res Rev 85: 17-28 (1983)]**PEER REVIEWED**

Volatilization from Water/Soil:

The Henry's Law constant for ethylbenzene is 7.88X10-3 atm-cu m/mole(1). This Henry's Law constant indicates that ethylbenzene will volatilize from water surfaces(2). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec)(2) is estimated as 1.1 hr(SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec)(2) is estimated as 99 hr(SRC). Ethylbenzene's Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). The potential for volatilization of ethylbenzene from dry soil surfaces may exist(SRC) based upon a vapor pressure of 9.6 mm Hg(3).

Environmental Water Concentrations:

DRINKING WATER: In surveys of representative US municipal water supplies, ethylbenzene has been detected in most cases(1,2,4-8,10). Values for 3 New Orleans finished drinking waters ranged 1.6 to 2.3 ppb(6). Chicago Central Water Works on Lake Michigan measured 4 ppb(8). It has been found in the water supply for Evansville, IN on the Ohio River(7). 6 of 10 US cities were found to be positive(1,4). One US city had 1 of 4 samples pos with a 1 ppb avg, while another reported no positive samples(5). Tap water from bank infiltrated Rhine River water in the Netherlands measured 30 ppb in one study(3). Zurich, Switzerland tap water - detected not quantified(9). 1982 US groundwater supply survey, random samples of finished water supplies using groundwater as a source, 466 random samples, 0.6%, pos (0.5 ppb detection limit), 0.8 ppb median, 1.1 ppb max(10).

URBAN/SUBURBAN: Values for major western US cities ranged from 0.1 to 27.7 ppb(1,5,6,7,13), with the avg being 2.68 ppb(SRC). Representative centers in New Jersey had a range of 0.17 to 0.33 ppb avg, 107 of 110 samples pos(4). Ethylbenzene was detected but not quantified in another New Jersey study(11). It has been detected in 6 USSR cities, including Lenningrad as well as New York and Paris(8-10). The Hague, Netherlands - 5 ppb(2); Sidney Australia - 1.3 ppb(12); Japan - 0.2 ppb and Frankfurt-am-Main, Germany - 1 ppb(14). 3 sites in England away from traffic - 16.1 to 18.8 parts/trillion avg, 2 sites with heavy traffic 28.7 to 33.9 parts/trillion avg(3). 8.7 ppb measured in the atmosphere of Zurich, Switzerland(17). 669 samples from the US had a median concn of 1.2 ppb(15). 36 Chicago metropolitan area homes tested - 36% in outdoor air(16). Gas-phase concn (ng/cu m) during 7 rain events, Portland, OR, Feb-Apri 1984, 7 rain events 100% pos, 780-2800, 1300 avg(20). Concn (ppb), Exhibition Road, London, May-Aug 1983, 267 samples, 100% pos, 0.05-2.17, 0.78 avg(18); June-July 1982, 256 samples, not detected-3.3, 0.88 avg(19). US 1979-1984, 15 cities, 1-2 weeks of sampling/site, overall range, not detected-31.5 ppb; range of avg, 0.6-4-6 ppb, avg of avg, 1.9 ppb(21). Ethylbenzene outdoor air concns in Rio de Janeiro, Brazil ranged from 3.1-7.4 ug/cu m(22).

TSCA Requirements:

Pursuant to section 8(d) of TSCA, EPA promulgated a model Health and Safety Data Reporting Rule. The section 8(d) model rule requires manufacturers, importers, and processors of listed chemical substances and mixtures to submit to EPA copies and lists of unpublished health and safety studies. Ethylbenzene is included on this list.
[40 CFR 716.120 (7/1/99)]**PEER REVIEWED**

CERCLA Reportable Quantities:

Persons in charge of vessels or facilities are required to notify the National Response Center (NRC) immediately, when there is a release of this designated hazardous substance, in an amount equal to or greater than its reportable quantity of 1000 lb or 454 kg. The toll free number of the NRC is (800) 424-8802; In the Washington D.C. metropolitan area (202) 426-2675. The rule for determining when notification is required is stated in 40 CFR 302.4 (section IV. D.3.b).
[40 CFR 302.4 (7/1/99)]**PEER REVIEWED**

RCRA Requirements:

F003; When ethylbenzene is a spent solvent, it is classified as a hazardous waste from a nonspecific source (F003), as stated in 40 CFR 261.31, and must be managed according to State and/or Federal hazardous waste regulations.
[40 CFR 261.31 (7/1/99)]**PEER REVIEWED**

Atmospheric Standards:

This action promulgates standards of performance for equipment leaks of Volatile Organic Compounds (VOC) in the Synthetic Organic Chemical Manufacturing Industry (SOCMI). The intended effect of these standards is to require all newly constructed, modified, and reconstructed SOCMI process units to use the best demonstrated system of continuous emission reduction for equipment leaks of VOC, considering costs, non air quality health and environmental impact and energy requirements. Ethylbenzene is produced, as an intermediate or a final product, by process units covered under this subpart.
[40 CFR 60.489 (7/1/99)]**PEER REVIEWED**

Listed as a hazardous air pollutant (HAP) generally known or suspected to cause serious health problems. The Clean Air Act, as amended in 1990, directs EPA to set standards requiring major sources to sharply reduce routine emissions of toxic pollutants. EPA is required to establish and phase in specific performance based standards for all air emission sources that emit one or more of the listed pollutants. Ethylbenzene is included on this list.

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Do not use dry chemical extinguishers to control fires involving nitromethane or nitroethane. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency

Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Office, 1997. 132]**PEER REVIEWED**

Preventive Measures:

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 132]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.

Laboratory Methods:

Clinical Laboratory Methods:

IN BLOOD BY ULTRAVIOLET-SPECTROPHOTOMETRIC METHOD.
[Browning, E. Toxicity and Metabolism of Industrial Solvents. New York: American Elsevier, 1965. 91]**PEER REVIEWED**

An automated high performance liquid chromatographic method for the direct determination of urinary concentrations of phenyl glyoxylic acid and mandelic acid, metabolites of styrene or ethylbenzene, is described. The method is simple and specific. Urine can be analyzed without solvent extraction. Analysis can be performed satisfactorily within 15 minutes for samples containing hippuric acid, o-, m- and p-methyl hippuric acids, phenyl glyoxylic acid, and mandelic acid, and within 15 minutes for those containing hippuric acid, phenyl glyoxylic acid and mandelic acid.
[Ogata M, Taguchi T; Int Arch Occup Environ Health 59 (3): 263-72 (1987)]**PEER REVIEWED**

Analytic Laboratory Methods:

EPA Method 624. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the analysis of purgeable organics including ethylbenzene in the municipal and industrial discharges. Under the prescribed conditions, for ethylbenzene the method has a detection limit of 7.2 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 1624. Isotope Dilution Purge-and-Trap Gas Chromatography/Mass Spectrometry. This

method is applicable for the determination of volatile organic compounds in municpal and industrial discharges. By adding a known amount of a labeled compound to every sample prior to purging, a correction of recovery of the pollutant can be made. If labeled compounds are not available, an internal standard method is used. Under the prescribed conditions, for both the labeled, and unlabeled ethylbenzene the method has a minimum detection level 10 ug/l.The established acceptance performance criteria at 20 ug/l is 9.6 ug/l for the standard deviation of the recovery, with the average recovery of 15.6 to 28.5 ug/l and the labeled cmpd recovery ranging from below detection to 203%.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 602. Purge-and-Trap Gas Chromatography with photoionization detection for the determination of purgeable aromatics including ethylbenzene in municipal and industrial discharges. Under the prescribed conditionss for ethylbenzene the detection limit is 0.2 ug/l. The method is applicable for use in the concentration range from the method detection limit to times that limit. Precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 524.2. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the determination of volatile aromatic compounds in water including finished drinking water, raw source water, and drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.06 ug/l and a relative standard deviation of 8.6% with a wide bore capillary column, and a method detection limit of 0.03 ug/l and a relative standard deviation of 5.3% with a narrow bore capillary column.
[USEPA; Methods for the Determinatioon of Organic Compounds in Finished Drinking Water and Raw Source Water (19860]**PEER REVIEWED**

EPA Method 503.1. Purge-and-Trap Gas Chromatography with a Photoionization Detector. The method is applicable for the determination of volatile aromatic and unsaturated organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.002 ug/l and a relative standard deviation of 8.5%. Overall precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of sample matrix.
[USEPA; Methods for the Determination of Organic Compouds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 502.2: Purge-and-Trap Capillary Column Gas Chromatography with Photoionization and Electrolytic Conductivity Detectors in Series. The method is applicable for the determination of volatile organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.005 ug/l, a percent recovery of 101%, and a standard deviation of 1.4 using the photoionization detector; and there is no data given for the following: the method detection limit, a percent recovery, or the standard deviation of recovery using the electrolytic conductivity detector.

Human Health Effects:

Toxicity Summary:

The acute toxicity of ethylbenzene to algae, aquatic invertebrates and fish is moderate. ... No information is available regarding chronic exposure of aquatic organisms to ethylbenzene. There is limited information regarding the toxicity of ethylbenzene to bacteria ... There are no data for terrestrial plants, birds, or wild mammals. Human exposure to ethylbenzene occurs mainly by inhalation; 40-60% of inhaled ethylbenzene is retained in the lung. Ethylbenzene is extensively metabolized, mainly to mandelic and phenylglyoxylic acids. These urinary metabolites can be used to monitor human exposures. Ethylbenzene has low acute and chronic toxicity for both animals and humans. It is toxic to the central nervous system and is an irritant of mucous membranes and the eyes. ... Ethylbenzene is an inducer of liver microsomal enzymes. It is not mutagenic or teratogenic ... No information is available on reproductive toxicity or carcinogenicity of ethylbenzene. A guidance value of 22 mg/ cu m (5 ppm) has been calculated from animal studies. /This value would correspond to a weekly absorbed dose (daily ventilation of 20 cu m with 60% retention) of about 2000 mg./ The estimated exposure of the general population (even in the worst case situation) is below this guidance value. Long term occupational exposure to ethylbenzene concentrations estimated to be of this order of magnitude did not cause adverse health effects in workers.

[Environmental Health Criteria 186: Ethylbenzene pp. 19-20 (1996) by the International Programme on Chemical Safety (IPCS) under the joint sponsorship of the United Nations Environment Programme, the International Labour Organisation and the World Health Organization.]**QC REVIEWED**

Evidence for Carcinogenicity:

... /IT HAS BEEN/ SHOWN THAT CONCN OF 1 MG/L & EVEN 0.1 MG/L MAY BE DANGEROUS & MAY PRODUCE FUNCTIONAL & ORGANIC DISTURBANCES (NERVOUS SYSTEM DISORDERS, TOXIC HEPATITIS & UPPER RESP TRACT COMPLAINTS). CONCN AS LOW AS 0.01 MG/L MAY LEAD TO ... INFLAMMATION OF UPPER RESP TRACT MUCOSA.
[International Labour Office. Encyclopedia of Occupational Health and Safety. Vols. I&II. Geneva, Switzerland: International Labour Office, 1983. 2114]**PEER REVIEWED**

Ethyl benzene vapor has a transient irritant effect on human eyes at 200 ppm in air. At 1000 ppm on the first exposure it is very irritating and causes tearing, but tolerance rapidly develops. At 2000 ppm eye irritation and lacrimation are immediate and severe; 5000 ppm causes intolerable irritation of the eyes and nose.

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 80,726 workers (21,785 of these are female) are potentially exposed to ethylbenzene in the US(1). Occupational exposure to ethylbenzene may occur via inhalation at municipal waste composting facilities where the air concn was found to be 78,000-178,000 ug/cu m(2),and through inhalation and dermal contact with this compound at worplaces where ethylbenzene is produced or used(SRC). The general population may be exposed to ethylbenzene via inhalation of ambient air, ingestion of foods and fish, and drinking contaminated water, and dermal contact with this compound and other products such as gasoline which contains ethylbenzene(SRC).
[(1) NIOSH; National Occupational Exposure Survey (NOES) (1983) (2) Eitzer BD; Environ Sci Technol 29: 896-902 (1995)]**PEER REVIEWED**

Body Burden:

Ethylbenzene was detected, not quantified, in 8 of 8 samples of mother's milk from 4 US urban areas(1). 16.5% of 387 expired air samples taken from 54 normal, healthy, urban volunteers were positive for ethylbenzene concn with an avg of 1.8 ng/l expired air(2). Whole blood samples from 250 subjects ranged in ethylbenzene concns from not detected to 59 ppb, with an avg of 1.0 ppb(3).

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 80,726 workers (21,785 of these are female) are potentially exposed to ethylbenzene in the US(1). Occupational exposure to ethylbenzene may occur via inhalation at municipal waste composting facilities where the air concn was found to be 78,000-178,000 ug/cu m(2),and through inhalation and dermal contact with this compound at worplaces where ethylbenzene is produced or used(SRC). The general population may be exposed to ethylbenzene via inhalation of ambient air, ingestion of foods and fish, and drinking contaminated water, and dermal contact with this compound and other products such as gasoline which contains ethylbenzene(SRC).

The following Overview, *** ETHYLBENZENE ***, is relevant for this HSDB record chemical.

Life Support:

- This overview assumes that basic life support measures have been instituted.

Clinical Effects:

SUMMARY OF EXPOSURE

0.2.1.1 ACUTE EXPOSURE

- Ethylbenzene is an eye, skin, and mucous membrane irritant. Narcosis may also occur.
- Exposure to ethylbenzene at significant concentrations may cause profuse lacrimation, conjunctivitis, nasal and respiratory tract irritation, chest constriction, vertigo, headache, irritability, and possibly functional nervous system disturbances at high concentrations.
- Chronic exposure in humans may caused fatigue, sleepiness, headache, and irritation of the eyes and respiratory tract.
- In experimental animals, exposure to ethylbenzene may cause eye, skin, and mucous membrane irritation; changes in liver and kidney weights; CNS depression; pulmonary edema; and respiratory failure.

HEENT

0.2.4.1 ACUTE EXPOSURE

- Ethylbenzene can be an eye irritant.

RESPIRATORY

0.2.6.1 ACUTE EXPOSURE

- Ethyl benzene is a respiratory tract irritant and is a

pulmonary aspiration hazard following large ingestions. In fatal cases, pulmonary edema had developed; death occurs in respiratory failure. However, human studies demonstrated no signs or symptoms of respiratory tract irritation at 85 and 100 ppm.

NEUROLOGIC

0.2.7.1 ACUTE EXPOSURE

- Ethyl benzene has CNS depressant (narcotic) properties at high concentrations.
- CNS symptoms may include headache, nausea, weakness, incoordination, dizziness, sleepiness, loss of coordination, judgement, and consciousness, and coma or death may occur with significant exposure. Cerebral edema may occur in fatal poisonings.

GASTROINTESTINAL

0.2.8.1 ACUTE EXPOSURE

- Ethyl benzene is a pulmonary aspiration hazard following ingestion, and is toxic with ingestion exposure. Ingestion would be predicted to cause GI tract irritation or burns.

HEPATIC

0.2.9.1 ACUTE EXPOSURE

- Slight changes in the liver occurred in rats exposed to 600 ppm for up to 16 weeks.

GENITOURINARY

0.2.10.1 ACUTE EXPOSURE

- Slight changes in the kidneys occurred in rats exposed to 600 ppm for up to 16 weeks.

HEMATOLOGIC

0.2.13.1 ACUTE EXPOSURE

- Ethyl benzene has been shown NOT to have the myelotoxic activity associated with BENZENE.

DERMATOLOGIC

0.2.14.1 ACUTE EXPOSURE

- Dermal contact causes inflammation and erythema. Ethyl benzene can be absorbed through intact skin.

REPRODUCTIVE HAZARDS

- Ethyl benzene is teratogenic and fetotoxic in experimental animals, and has been detected in umbilical cord blood.

Laboratory:

- Urinary levels of mandelic acid can be used as an indicator of exposure to ethylbenzene.

Treatment Overview:

SUMMARY EXPOSURE

- FIRST AID (NIOSH, 2000) -
  1. EYE EXPOSURE - Immediately wash the eyes with large amounts of water, occasionally lifting the lower and upper lids. Get medical attention immediately. Contact lenses should not be worn when working with this chemical.
  2. DERMAL EXPOSURE - Flush the contaminated skin with water promptly. If this chemical penetrates the clothing, immediately remove the clothing and flush the skin with water promptly. If irritation persists after washing, get medical attention.
  3. INHALATION EXPOSURE - Move the exposed person to fresh air at once. If breathing has stopped, perform mouth-to-mouth resuscitation. Keep the affected person warm and at rest. Get medical attention as soon as possible.
  4. ORAL EXPOSURE - If this chemical has been swallowed, get medical attention immediately.
  5. TARGET ORGANS - Eyes, skin, respiratory tract, and central nervous system.
- GENERAL -
  1. Move victims of inhalation exposure from the toxic environment and administer 100% humidified supplemental oxygen with assisted ventilation as required. Exposed skin and eyes should be copiously flushed with water. Because of the potential for rapid onset of CNS depression or seizures with possible aspiration of gastric contents, EMESIS SHOULD NOT BE INDUCED. Cautious gastric lavage followed by administration of activated charcoal may be of benefit if the patient is seen soon after the exposure.
- INHALATION EXPOSURE -
  1. DECONTAMINATION: Move patient to fresh air. Monitor for respiratory distress. If cough or difficulty in breathing develops, evaluate for respiratory tract irritation, bronchitis, or pneumonitis. Administer 100 percent humidified supplemental oxygen with assisted ventilation as required.
  2. If bronchospasm and wheezing occur, consider treatment with inhaled sympathomimetic agents.
  3. PULMONARY EDEMA (NONCARDIOGENIC): Maintain ventilation and oxygenation and evaluate with frequent arterial blood gas or pulse oximetry monitoring. Early use of

PEEP and mechanical ventilation may be needed.

- DERMAL EXPOSURE -
  1. DECONTAMINATION: Wash exposed area extremely thoroughly with soap and water. A physician may need to examine the area if irritation or pain persists.
  2. Treat dermal irritation or burns with standard topical therapy. Patients developing dermal hypersensitivity reactions may require treatment with systemic or topical corticosteroids or antihistamines.
  3. Some chemicals can produce systemic poisoning by absorption through intact skin. Carefully observe patients with dermal exposure for the development of any systemic signs or symptoms and administer symptomatic treatment as necessary.
- EYE EXPOSURE -
  1. DECONTAMINATION: Exposed eyes should be irrigated with copious amounts of tepid water for at least 15 minutes. If irritation, pain, swelling, lacrimation, or photophobia persist, the patient should be seen in a health care facility.
- ORAL EXPOSURE -
  1. Because of the potential for CNS depression or gastrointestinal tract irritation, do not induce emesis.
  2. Weigh the potential toxicity of the amount of ethylbenzene ingested against the substantial risk of pulmonary aspiration of gastric contents. Ethylbenzene may "wick" up around a lavage tube, allowing pulmonary aspiration.
     a. Significant esophageal or gastrointestinal tract irritation or burns may occur following ingestion. The possible benefit of early removal of some ingested material by cautious gastric lavage must be weighed against potential complications of bleeding or perforation.
  3. GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
     a. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation;

and trivial or non-toxic ingestion.

4. ACTIVATED CHARCOAL/CATHARTIC: Administer charcoal slurry, aqueous or mixed with saline cathartic or sorbitol. The FDA suggests 240 mL of diluent/30 g of charcoal. Usual charcoal dose is 25 to 100 grams in adults and adolescents, 25 to 50 grams in children (1 to 12 years old), and 1 gram/kilogram in infants less than 1 year old.
   a. Routine use of cathartics is NOT recommended. If used, administer only ONE dose of cathartic. Administer one dose of a cathartic, mixed with charcoal or given separately. See "Treatment: Prevention of Absorption" in the main document.
5. Observe patients with ingestion carefully for the possible development of esophageal or gastrointestinal tract irritation or burns. If signs or symptoms of esophageal irritation or burns are present, consider endoscopy to determine the extent of injury.

ORAL EXPOSURE

- Because of the potential for CNS depression or gastrointestinal tract irritation, Do NOT induce emesis.
- Weigh the potential toxicity of the amount of ethylbenzene ingested against the substantial risk of aspiration. Ethylbenzene may "wick" up around a lavage tube, allowing pulmonary aspiration.
  1. Significant esophageal or gastrointestinal tract irritation or burns may occur following ingestion. The possible benefit of early removal of some ingested material by cautious gastric lavage must be weighed against potential complications of bleeding or perforation.
- GASTRIC LAVAGE: Consider after ingestion of a potentially life-threatening amount of poison if it can be performed soon after ingestion (generally within 1 hour). Protect airway by placement in Trendelenburg and left lateral decubitus position or by endotracheal intubation. Control any seizures first.
  1. CONTRAINDICATIONS: Loss of airway protective reflexes or decreased level of consciousness in unintubated patients; following ingestion of corrosives; hydrocarbons (high aspiration potential); patients at risk of hemorrhage or gastrointestinal perforation; and trivial or non-toxic ingestion.
- ACTIVATED CHARCOAL/CATHARTIC: Administer charcoal slurry, aqueous or mixed with saline cathartic or sorbitol. The FDA suggests 240 mL of diluent/30 g of

Animal Toxicity Studies:

Toxicity Summary:

The acute toxicity of ethylbenzene to algae, aquatic invertebrates and fish is moderate. ... No information is available regarding chronic exposure of aquatic organisms to ethylbenzene. There is limited information regarding the toxicity of ethylbenzene to bacteria ... There are no data for terrestrial plants, birds, or wild mammals. Human exposure to ethylbenzene occurs mainly by inhalation; 40-60% of inhaled ethylbenzene is retained in the lung. Ethylbenzene is extensively metabolized, mainly to mandelic and phenylglyoxylic acids. These urinary metabolites can be used to monitor human exposures. Ethylbenzene has low acute and chronic toxicity for both animals and humans. It is toxic to the central nervous system and is an irritant of mucous membranes and the eyes. ... Ethylbenzene is an inducer of liver microsomal enzymes. It is not mutagenic or teratogenic ... No information is available on reproductive toxicity or carcinogenicity of ethylbenzene. A guidance value of 22 mg/ cu m (5 ppm) has been calculated from animal studies. /This value would correspond to a weekly absorbed dose (daily ventilation of 20 cu m with 60% retention) of about 2000 mg./ The estimated exposure of the general population (even in the worst case situation) is below this guidance value. Long term occupational exposure to ethylbenzene concentrations estimated to be of this order of magnitude did not cause adverse health effects in workers.
[Environmental Health Criteria 186: Ethylbenzene pp. 19-20 (1996) by the International Programme on Chemical Safety (IPCS) under the joint sponsorship of the United Nations Environment Programme, the International Labour Organisation and the World Health Organization.]**QC REVIEWED**

Evidence for Carcinogenicity:

CLASSIFICATION: D; not classifiable as to human carcinogenicity. BASIS FOR CLASSIFICATION: nonclassifiable due to lack of animal bioassays and human studies. HUMAN CARCINOGENICITY DATA: None. ANIMAL CARCINOGENICITY DATA: None.

Concn of < 0.25 mg/l can cause tainting of fish flesh.
[Cleland, J.G., G.L. Kingsbury. Multimedia Environmental Goals for Environmental Assessment. Volume 1. EPA-600/7-77-136a. Research Triangle Park, NC: EPA, Nov. 1977.,p. E-148]**PEER REVIEWED**

Neither maternal toxicity nor embryotoxicity was observed in gravid rabbits exposed to ethylbenzene /by inhalation/ at 100 or 1000 ppm.
[NIOSH; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol p.iii (1981) NIOSH Contract No. 210-79-0037]**PEER REVIEWED**

Neither maternal toxicity nor embyrotoxicity was observed /in pregnant rats/ exposed to ethylbenzene /by inhalation/ at 100 ppm ... but /1000 ppm/ induced some indications of toxicity. ... A significant increase in the incidence of extra ribs was detected in rat fetuses exposed in utero to the high level.
[NIOSH; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol p.iii (1981) NIOSH Contract No. 210-79-0037]**PEER REVIEWED**

Mice, B6C3F1 Fischer-344 rats, and /rabbits /New Zealand/ (five/sex/group) were exposed by inhalation to ethylbenzene vapors for 6 hr/day, 5 days/week for 4 weeks (20 exposures). Rats and mice received 0, 99, 382, or 782 ppm ethylbenzene while rabbits received 0, 382, 782, or 1610 ppm. No changes were evident in mortality patterns, clinical chemistries, urinalyses, or treatment-related gross/microscopic (including ophthalmologic) lesions. Rats exhibited sporadic lacrimation and salivation, as well as significantly increased liver weights at 382 and 782 ppm, and small increases in leukocyte counts at 782 ppm. Males at this exposure level also showed marginal elevations in platelet counts. In mice, females showed statistically increased absolute and relative liver weights at 382 and 782 ppm while males had statistically increased relative liver-to-brain weight ratios only at 782 ppm. Female rabbits at the high exposure level of 1610 ppm gained weight more slowly than controls (not statistically significant); males showed a similar transient downward trend after 1 week, but showed no differences from controls at study's end. A no observed adverse effect level (NOAEL) of 382 ppm appears appropriate for rats and mice with a lowest observed adverse effect level (LOAEL) of 782 ppm. A NOAEL of 782 ppm and LOAEL of 1610 ppm are appropriate for rabbits.
[Cragg ST et al; Fundam Appl Toxicol 13 (3): 399-408 (1989)]**PEER REVIEWED**

Repeated application of undiluted ethyl benzene to the ear and shaved abdominal area of rabbits (10-20 applications over a period of 2-4 wk) resulted in erthyema, edema, and superficial necrosis. ... Two drops of ethyl benzene into the conjunctival sac produced only a slight irritation of the conjunctival membranes but no corneal injury.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure

Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 581]**PEER REVIEWED**

Inhalation of 2600 mg/cu m (600 ppm) ethyl benzene 7 hr/day, 5 days/wk for 186 days caused degeneration of the germinal epithelium in the testes of rabbits and monkeys but not of rats. Pregnant rats exposed at 100 or 1000 ppm 6 hr/day for 3 wk prior to mating and on days 1-19 of gestation had pups with a significant increase ($p < 0.05$) in extra rib formation; at the higher dose, maternal toxicity was indicated by increased liver, kidney, and spleen weights.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 582]**PEER REVIEWED**

TSCA Test Submissions:

In a single generation reproduction study, 380 female and 60 male Wistar rats were exposed to ethylbenzene at average daily concentrations of 97 or 959 ppm 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily on gestation days (GD) 1-19 at concentrations of 96 (low) or 985 (high) ppm. Animals were sacrificed and examined on GD 21. No significant differences were observed between treatment groups and controls in food consumption, gestational body weights (of pregnant rats), organ weights (of male rats), histopathology of liver, kidney or lungs, percent pregnancy, no. of corpora lutea, no. of implants, total live or dead fetuses, no. of live or dead fetuses per litter, no. of resorptions per litter and percent litters with resorptions. A significant difference (ANOVA, Duncan's multiple range test) was observed in pregestational body weights in both treatment groups. Maternal toxicity was indicated in the high dose groups (dosed at the high level during both periods or dosed with air during pregestational and with the high level during gestation) by significant differences (ANOVA, Duncan's multiple range test) in liver, spleen and kidney weights. Statistically significant differences were seen in mean crown-rump length (in the group which was dosed at the high level during both periods), supernumerary ribs (in the 2 high dose groups and the group which was dosed with air

pregestationally and with the low level during gestation) and rudimentary rib incidence (in the group dosed with air during pregestation and with the high level during gestation).
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150]
UNREVIEWED

In a single generation reproduction study 96 New Zealand White rabbits were artifically inseminated and exposed to ethylbenzene at average daily concentrations of 99 or 962 ppm 7 hours per day, through gestation day (GD) 24. Animals were sacrificed and examined on GD 30. Mortality was observed in 2 does, 1 from each dose group. No significant differences were observed between treatment groups and controls in the following: food consumption; body weight; weight gain; lung, kidney, and spleen mean weights; histopathology of liver, kidney, or lungs; percent pregnancy; no. of corpora lutea; no. of implants; total live or dead fetuses; no. of dead fetuses per litter; no. of resorptions per litter; percent litters with resorptions; and skeletal, visceral, or external parameters in fetuses. Significant differences (ANOVA, Duncan's multiple range test) relative to controls were observed in liver weights of the high dose group and in mean number of live fetuses per litter in both treatment groups.
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150]
UNREVIEWED

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 89, 77, and 77 female Wistar rats exposed to 0, 100, and 1000 ppm of the test material respectively by inhalation for 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily through the 19th day of gestation. The rats were killed and examined at the 21st day of gestation. No significant differences were observed in food consumption and body weights during progestational and gestational exposure periods. At 1000 ppm relative and absolute liver, spleen, and kidney weights were significantly greater than controls and or the 100 ppm group. No treatment-related histological changes were observed. Body weights, placenta weights, and sex ratios were all within normal limits. There were no significant increases in major malformations or minor anomalies. Litters were examined for the presence of external, visceral, and skeletal defects as well as the incidence of growth retardation and intrauterine mortality. A statistically significant increased incidence of fetal supernumary ribs was observed at the 1000 ppm exposure. It was concluded that ethylbenzene caused maternal and developmental toxicity (significant increase in extra ribs) at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167]
UNREVIEWED

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 24, 23, and 22 New Zealand white rabbits artificially inseminated and exposed for 7 hours daily to 0, 100, and 1000 ppm of the test material respectively until the 24th day of gestation. Neither maternal toxicity nor embryotoxicity was observed in rabbits exposed to ethylbenzene at 100 or 1000 ppm. Rabbits had increased maternal liver weights at 1000 ppm and reduced mean number of live fetuses at 100 and 1000 ppm. No significant differences were observed in food consumption and weight gain. No treatment-related organ weight or histopathological changes were observed. Fetal size (weight and length), placenta weights, and sex ratios were all within normal limits. The sex ratios of the groups were not affected by treatment. No statistically

significant incidences of major malformations, minor anomalies, or common variants were observed. It was concluded that the test material did not induce significant maternal toxicity, embryomortality, growth retardation, or teratogenicity at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167] **UNREVIEWED**

The frequency of chromosomal aberrations was evaluated in vitro by exposing rats liver (RL1) cells to 25, 50 or 100 ug of ethyl benzene/ml. No increases in the frequency of chromatid gaps, chromatid breaks or total chromosome aberrations was observed at any dose level. Ethyl benzene did not induce chromosome damage in this assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The mutagenicity of ethyl benzene was evaluated in E. coli tester strains WP2 and WP2uvrA and in Salmonella tester strains TA98, TA100, TA1535, TA1537, and TA1538 (Ames test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of preliminary bacterial toxicity determinations, ethyl benzene, in DMSO, was tested for mutagenicity at concentrations of 0.2, 2.0, 20.0, 200.0, and 2000.0 ug/plate using the direct plate incorporation method. Ethyl benzene did not cause a positive response in any of the tester strains with or without metabolic activation.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The ability of ethyl benzene to induce conversion of differentially inactive alleles to wild-type alleles in Saccharomyces cervisiae was examined in the mitotic gene conversion assay. The cultures were dosed with solutions of 20 ul (in the absence of added metabolic action provided by Aroclor-induced rat liver S9 fraction) or 25 ul (with S9) of 1, 10, 50, 100 or 500 mg ethyl benzene/ml. Ethyl benzene did not produce an increase mitotic gene conversion, either with or without added metabolic activation, and was not considered to be mutagenic in the assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

SUBACUTE EXPOSURE OF MALE RATS TO 2000 PPM PRODUCED INCREASES OF DOPAMINE & NORADRENALINE LEVELS & TURNOVER IN VARIOUS PARTS OF HYPOTHALAMUS & MEDIAN EMINENCE 16-18 HR FOLLOWING LAST EXPOSURE.
[ANDERSON K ET AL, TOXICOL APPL PHARMACOL 60 (3): 535 (1981)]**PEER REVIEWED**

Rats inhaling 600, 1200, or 2400 mg ethylbenzene/cu m for 24 hr/day from days 7-15 of pregnancy showed mild toxicity. The highest dose retarded skeletal development and weight gain in the fetuses and increased the incidence of extra ribs. Sacral displacement with abnormal development was observed in 2 instances. Thus, ethylbenzene, has some embryotoxic and teratogenic activity.

[Tatrai E et al; Egeszsegtudomany 26 (3): 297-303 (1982)]**PEER REVIEWED**

Ethylbenzene was investigated ... as a sensory irritant in mice. The concn necessary to depress the respiratory rate by 50% (RD 50) due to sensory irritation of the upper respiratory tract was 4060 ppm. ... A model for the sensory irritating action ... was proposed on the basis of ... physical interaction with a receptor protein.
[Nielsen GD, Alarie Y; Toxical Appl Pharmacol 65 (3): 459-77 (1982)]**PEER REVIEWED**

Drop application to rabbit eyes caused slight irritation and no corneal injury demonstrable by fluorescein staining. Standard testing on rabbit eyes gave an injury grade of 2 on a scale of 10.
[Grant, W.M. Toxicology of the Eye. 3rd ed. Springfield, IL: Charles C. Thomas Publisher, 1986. 413]**PEER REVIEWED**

Rats were exposed for 3 days by inhalation to 2000 ppm of a xylene mixture, or ... ethylbenzene. All solvents increased hepatic cytochrome p450 concn and NADPH-cytochrome C reductase activity. The ability of ethylbenzene to modify the metabolism of other potentially toxic substances in liver, kidney, and lung microsomes suggested the possibility of synergistic toxic responses.
[Toftgard R, Nilsen OG; Toxicol 23 (2-3): 197-212 (1982)]**PEER REVIEWED**

Concn of < 0.25 mg/l can cause tainting of fish flesh.
[Cleland, J.G., G.L. Kingsbury. Multimedia Environmental Goals for Environmental Assessment. Volume 1. EPA-600/7-77-136a. Research Triangle Park, NC: EPA, Nov. 1977.,p. E-148]**PEER REVIEWED**

Neither maternal toxicity nor embryotoxicity was observed in gravid rabbits exposed to ethylbenzene /by inhalation/ at 100 or 1000 ppm.
[NIOSH; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol p.iii (1981) NIOSH Contract No. 210-79-0037]**PEER REVIEWED**

Neither maternal toxicity nor embyrotoxicity was observed /in pregnant rats/ exposed to ethylbenzene /by inhalation/ at 100 ppm ... but /1000 ppm/ induced some indications of toxicity. ... A significant increase in the incidence of extra ribs was detected in rat fetuses exposed in utero to the high level.
[NIOSH; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol p.iii (1981) NIOSH Contract No. 210-79-0037]**PEER REVIEWED**

Mice, B6C3F1 Fischer-344 rats, and /rabbits /New Zealand/ (five/sex/group) were exposed by inhalation to ethylbenzene vapors for 6 hr/day, 5 days/week for 4 weeks (20 exposures). Rats and mice received 0, 99, 382, or 782 ppm ethylbenzene while rabbits received 0, 382, 782, or 1610 ppm. No changes were evident in mortality patterns, clinical chemistries, urinalyses, or treatment-related gross/microscopic (including ophthalmologic) lesions. Rats exhibited sporadic lacrimation and salivation, as well as significantly increased liver weights at 382 and 782 ppm, and small increases in leukocyte counts at 782 ppm. Males at this exposure level also showed marginal elevations in platelet counts. In mice, females showed statistically increased absolute and relative liver weights at 382 and 782 ppm while males had statistically increased relative liver-to-brain weight ratios only at 782 ppm. Female rabbits at the high exposure level of 1610 ppm gained weight more slowly than controls (not statistically significant); males

showed a similar transient downward trend after 1 week, but showed no differences from controls at study's end. A no observed adverse effect level (NOAEL) of 382 ppm appears appropriate for rats and mice with a lowest observed adverse effect level (LOAEL) of 782 ppm. A NOAEL of 782 ppm and LOAEL of 1610 ppm are appropriate for rabbits.
[Cragg ST et al; Fundam Appl Toxicol 13 (3): 399-408 (1989)]**PEER REVIEWED**

Repeated application of undiluted ethyl benzene to the ear and shaved abdominal area of rabbits (10-20 applications over a period of 2-4 wk) resulted in erthyema, edema, and superficial necrosis. ... Two drops of ethyl benzene into the conjunctival sac produced only a slight irritation of the conjunctival membranes but no corneal injury.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 581]**PEER REVIEWED**

Inhalation of 2600 mg/cu m (600 ppm) ethyl benzene 7 hr/day, 5 days/wk for 186 days caused degeneration of the germinal epithelium in the testes of rabbits and monkeys but not of rats. Pregnant rats exposed at 100 or 1000 ppm 6 hr/day for 3 wk prior to mating and on days 1-19 of gestation had pups with a significant increase ($p < 0.05$) in extra rib formation; at the higher dose, maternal toxicity was indicated by increased liver, kidney, and spleen weights.
[American Conference of Governmental Industrial Hygienists, Inc. Documentation of the Threshold Limit Values and Biological Exposure Indices. 6th ed. Volumes I,II, III. Cincinnati, OH: ACGIH, 1991. 582]**PEER REVIEWED**

TSCA Test Submissions:

In a single generation reproduction study, 380 female and 60 male Wistar rats were exposed to ethylbenzene at average daily concentrations of 97 or 959 ppm 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily on gestation days (GD) 1-19 at concentrations of 96 (low) or 985 (high) ppm. Animals were sacrificed and examined on GD 21. No significant differences were observed between treatment groups and controls in food consumption, gestational body weights (of pregnant rats), organ weights (of male rats), histopathology of liver, kidney or lungs, percent pregnancy, no. of corpora lutea, no. of implants, total live or dead fetuses, no. of live or dead fetuses per litter, no. of resorptions per litter and percent litters with resorptions. A significant difference (ANOVA, Duncan's multiple range test) was observed in pregestational body weights in both treatment groups. Maternal toxicity was indicated in the high dose groups (dosed at the high level during both periods or dosed with air during pregestational and with the high level during gestation) by significant differences (ANOVA, Duncan's multiple range test) in liver, spleen and kidney weights. Statistically significant differences were seen in mean crown-rump length (in the group which was dosed at the high level during both periods), supernumerary ribs (in the 2 high dose groups and the group which was dosed with air pregestationally and with the low level during gestation) and rudimentary rib incidence (in the group dosed with air during pregestation and with the high level during gestation).
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150]
UNREVIEWED

In a single generation reproduction study 96 New Zealand White rabbits were artifically inseminated and exposed to ethylbenzene at average daily concentrations of 99 or 962 ppm 7 hours per day, through gestation day (GD) 24. Animals were sacrificed and examined on GD 30. Mortality was observed in 2 does, 1 from each dose group. No significant differences were observed between treatment groups and controls in the following: food consumption; body weight; weight gain; lung, kidney, and spleen mean weights; histopathology of liver, kidney, or lungs; percent pregnancy; no. of corpora lutea; no. of implants; total live or dead fetuses; no. of dead fetuses per litter; no. of resorptions per litter; percent litters with resorptions; and skeletal, visceral, or external parameters in fetuses. Significant differences (ANOVA, Duncan's multiple range test) relative to controls were observed in liver weights of the high dose group and in mean number of live fetuses per litter in both treatment groups.
[Battelle Pacific Northwest Laboratories; Teratologic Assessment of Ethylbenzene and 2-Ethoxyethanol with Cover Letter Dated 061887, (1981), EPA Document No. 86870000402, Fiche No. OTS0513150]
UNREVIEWED

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 89, 77, and 77 female Wistar rats exposed to 0, 100, and 1000 ppm of the test material respectively by inhalation for 7 hours per day, 5 days per week for 3 weeks. They were then mated and exposed daily through the 19th day of gestation. The rats were killed and examined at the 21st day of gestation. No significant differences were observed in food consumption and body weights during progestational and gestational exposure periods.

At 1000 ppm relative and absolute liver, spleen, and kidney weights were significantly greater than controls and or the 100 ppm group. No treatment-related histological changes were observed. Body weights, placenta weights, and sex ratios were all within normal limits. There were no significant increases in major malformations or minor anomalies. Litters were examined for the presence of external, visceral, and skeletal defects as well as the incidence of growth retardation and intrauterine mortality. A statistically significant increased incidence of fetal supernumary ribs was observed at the 1000 ppm exposure. It was concluded that ethylbenzene caused maternal and developmental toxicity (significant increase in extra ribs) at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167] **UNREVIEWED**

Ethylbenzene (CAS# 100-41-4) was evaluated for developmental toxicity in 24, 23, and 22 New Zealand white rabbits artificially inseminated and exposed for 7 hours daily to 0, 100, and 1000 ppm of the test material respectively until the 24th day of gestation. Neither maternal toxicity nor embryotoxicity was observed in rabbits exposed to ethylbenzene at 100 or 1000 ppm. Rabbits had increased maternal liver weights at 1000 ppm and reduced mean number of live fetuses at 100 and 1000 ppm. No significant differences were observed in food consumption and weight gain. No treatment-related organ weight or histopathological changes were observed. Fetal size (weight and length), placenta weights, and sex ratios were all within normal limits. The sex ratios of the groups were not affected by treatment. No statistically significant incidences of major malformations, minor anomalies, or common variants were observed. It was concluded that the test material did not induce significant maternal toxicity, embryomortality, growth retardation, or teratogenicity at 1000 ppm.
[SHELL OIL CO; Teratogenic assessment of ethylbenzene and 2-ethoxyethanol; EPA 88-920002072, 1/01/81, Fiche No. OTS0539167] **UNREVIEWED**

The frequency of chromosomal aberrations was evaluated in vitro by exposing rats liver (RL1) cells to 25, 50 or 100 ug of ethyl benzene/ml. No increases in the frequency of chromatid gaps, chromatid breaks or total chromosome aberrations was observed at any dose level. Ethyl benzene did not induce chromosome damage in this assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The mutagenicity of ethyl benzene was evaluated in E. coli tester strains WP2 and WP2uvrA and in Salmonella tester strains TA98, TA100, TA1535, TA1537, and TA1538 (Ames test), both in the presence and absence of added metabolic activation by Aroclor-induced rat liver S9 fraction. Based on the results of preliminary bacterial toxicity determinations, ethyl benzene, in DMSO, was tested for mutagenicity at concentrations of 0.2, 2.0, 20.0, 200.0, and 2000.0 ug/plate using the direct plate incorporation method. Ethyl benzene did not cause a positive response in any of the tester strains with or without metabolic activation.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The ability of ethyl benzene to induce conversion of differentially inactive alleles to wild-type alleles in

Saccharomyces cervisiae was examined in the mitotic gene conversion assay. The cultures were dosed with solutions of 20 ul (in the absence of added metabolic action provided by Aroclor-induced rat liver S9 fraction) or 25 ul (with S9) of 1, 10, 50, 100 or 500 mg ethyl benzene/ml. Ethyl benzene did not produce an increase mitotic gene conversion, either with or without added metabolic activation, and was not considered to be mutagenic in the assay.
[Shell Oil; In Vitro Genotoxicity Studies with Ethyl Benzene Hydroperoxide (EBHP) and Ethyl Benzene, (1981), EPA Doc. No. 86-870001656, Fiche No. OTS0515732] **UNREVIEWED**

The purpose of this study was to clarify whether the blood concentration of inhaled toluene, ethylbenzene, m-xylene, or mesitylene can change after the concomitant pulmonary absorption of **ethyl acetate. (**Adult female Sprague-Dawley rats were exposed in a 20 liter glass chamber under dynamic conditions for 2 hours to various concentrations of the aromatics without or in combination with different concentrations of **ethyl acetate (**0, 1000, or 4000 ppm) in air. Concentration ranges were as follows: toluene, 140-690 ppm; ethylbenzene, 120-650 ppm; m-xylene, 100-560 ppm; mesitylene, 120-720 ppm; and **ethyl acetate,** 1000 or 4000 ppm. The coexposures with **ethyl acetate** lowered the blood concentrations of other inhaled aromatics. This reduction was statistically significant following a 2 hour exposure to 230 ppm toluene in combination with 1000 ppm **ethyl acetate,** 650 ppm ethylbenzene with 1000 ppm **ethyl acetate,** and 100 ppm m-xylene with 4000 ppm **ethyl acetate.)** Similarly a significant reduction of the blood level of the aromatics by **ethyl acetate** coinhalation was also observed at higher exposure concentrations with toluene and m-xylene. A metabolic interaction such as enhanced disposition of the aromatics, may be responsible for these effects. However, it is possible that the solubility of the solvents could be altered by the presence of **ethyl acetate.** It was concluded that coexposures to concentrations in the order of the threshold limit values (100 ppm for these solvents) with 400 ppm **ethyl acetate** should not be followed by a dangerous change of the blood levels of the aromatics.
[Freundt KJ et al; Bull Environ Contam Toxicol 42 (4): 495-8 (1989)]**PEER REVIEWED**

Stereochemical considerations in the metabolism of ethylbenzene and styrene were investigated. Three alternative methods used to determine the enantiomeric composition of mandelic-acid in urine arising from exposure to styrene or ethylbenzene were described. Of the methods described, the direct gas chromatographic resolution of the enantiomers on a chiral stationary phase was the best approach. It was a simple analytical technique which avoids complex derivatization. An additional advantage was that it may be used as a gas liquid chromatography/mass spectrometry method and thus has advantages of sensitivity and specificity. F-19 nuclear magnetic resonance proved a useful alternative technique and was invaluable if standards of the pure isomers were not available. The major advantage of the nuclear magnetic resonance approach was that absolute configuration of the compound could be elucidated. (In experimental studies, rats were administered ethylbenzene or styrene at 100 mg/kg by the stomach tube; urine was collected over 96 hours. Male volunteers were exposed to ethylbenzene vapor in an exposure chamber at 435 mg/cu m for 4 hours; urine samples were collected before, during and after exposure. The results indicate that whereas only the R-enantiomer of mardelic acid was excreted after ethylbenzene exposure, the mandelic acid from styrene was essentially racemic. In three workers exposed occupationally to styrene, R/S ratios of 1.16, 1.27 and 1.14 were found. A synthetic R/S mixture of mandelic acid has a R/S ratio of 1.03.)

Percutaneous absorption of benzene, toluene, ethylbenzene, and aniline was investigated in male HRS/J hairless mice. Stainless steel skin depots containing 100 to 150 mg of solid sorbent were fixed to the backs of anesthetized mice and charged with about 5 ul of (14)C tagged test solution. Expired air samples were obtained until 4 hours after exposure, when mice were killed and samples for radioactivity were obtained from the skin depot, the skin under the depot, a wiping of the skin under the depot, the carcass, feces, urine, and cage washings. Physical constants were determined for each test compound, including octanol/water partition coefficient, solubility, vapor pressure, melting and boiling points, and absorption and evaporation rates. Solvent recovery exceeded 90% in all mice with highest recovery in the skin depot. Average administered doses were 3.94 mg benzene, of which 0.99% was absorbed; 3.89 mg toluene (2.31% absorbed), 4.10 mg ethylbenzene (3.61% absorbed), and 4.68 mg aniline (4.76% absorbed). Excretion rate in expired air was fastest during the first 15 minutes of exposure except in mice treated with toluene or ethylbenzene, which demonstrated maximal excretion rate during the second 15 minutes after exposure. A two compartment model was suggested by the initial rapid and subsequent gradual decay of expired breath excretion. Vapor pressure and boiling point were significantly correlated with the applied radioactive dose absorbed. Absorption rates were found to be 56, 49, 37, and 2.3 ug per square centimeter per minute for benzene, toluene, ethylbenzene, and aniline, respectively.

Mechanism of Action:

The effect of styrene, toluene, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or toluene in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.

(1988)]**PEER REVIEWED**

Effect of monocyclic aromatic hydrocarbons, their metabolites, and their structure on brain dopamine was studied. Adult male New Zealand rabbits were exposed to 750 ppm toluene, styrene, ethylbenzene, vinyltoluene, 7-methylstyrene, xylenes, and fresh air. Six groups of eight rabbits received 4 mM/kg ip for 3 days of hippuric acid, mandelic acid, methylhippuric acid, phenylglyoxylic acid, or 7-methylmandelic acid. Animals were killed 12 hours after inhalation exposure or 24 hours after the last dose of acid. The hypothalamus, striatum, hippocampus, tuberoinfundibular area, and part of the brain cortex were treated with 0.2 molar perchloric acid, homogenized, desorbed on alumina, and centrifuged. Supernatant was filtered and used to measure homovanillic acid. Styrene induced a marked dopamine depletion and a significant increase in homovanillic acid concentration. Ethylbenzene and vinyltoluene produced a smaller, but statistically significant effect. Toluene, xylenes, and 7-methylstyrene were ineffective. Phenylglyoxylic acid caused a decrease in dopamine levels and a consistent rise in homovanillic acid in striatal and tuberoinfundibular regions. Mandelic acid elicited the same effect, but to a lesser degree. 7-Methylmandelic, methylhippuric, and hippuric acids evoked no response. Neither solvents nor their metabolites affected norepinephrine contents of brain areas in which this neurotransmitter reaches high concentrations. It was concluded that the results indicate that the changes in brain dopamine depend on metabolic interferences of some metabolites of aromatic solvents with dopamine catabolism. Only metabolites whose side chain may be transformed into a alpha-keto acid caused dopamine depletion.
[Romanelli A et al; J Appl Toxicol 6 (6): 431-5 (1986)]**PEER REVIEWED**

The effect of organic solvents on the CNS was discussed. The similarity of effects of different solvents is believed to be due to the formation of tetrahydroisoquinolines by nonenzymatic condensation of dopamine with metabolites of organic solvents having a reactive carbonyl group. The suspected metabolites are phenylglyoxylic- acid that is formed by metabolism of ethylbenzene, styrene, vinyltoluene; trichloroacetaldehyde, which derives from trichloroethylene, tetrachloroethylene; and trichloroethane; glyoxylic acid that is synthesized from ethyleneglycol and ethyleneglycolmonomethyl ether; formaldehyde that is metabolized from methanol; and acetaldehyde that is transformed from ethanol. The tuberoinfundibular dopaminergic system may represent a target for metabolites dissolved in the blood stream. The suggested mechanism implies a selective vulnerability of pituitary functions. The impairment of tuberoinfundibular activity may explain most of the behavioral changes observed with styrene and perhaps with other similar solvents. It appears that the majority of pathways that are affected in the hypothalamic control of gonadotropins in primates are adrenergic and dopaminergic. Occupational exposure to neurotoxins may cause repeated reversible CNS effects which are difficult to distinguish from the chronic effects. In workers exposed to styrene a relationship between recent exposure and measurable effects on CNS has been observed and prolonged exposure has failed to induce tolerance. It was concluded that although no excessive risk for Alzheimer disease and presenile dementia has been found, there is no indication that exposure to solvents does not cause irreversible or slowly reversible cognitive or neuropsychological impairment.
[Mutti A, Franchini I; Br J Ind Med 44 (11): 721-3 (1987)]**PEER REVIEWED**

Efforts were made to clarify the molecular basis of styrene toxicity on the dopaminergic systems and to evaluate whether the same mechanism was common to other solvents. Groups of male New Zealand rabbits were exposed to 750 ppm toluene, xylene, styrene, ethylbenzene, vinyltoluene, 7-methyl-styrene, or fresh air (control group). A significant depletion in both striatal and tubero infundibular dopamine was

caused styrene, ethylbenzene, and vinyltoluene. Methylation of the aromatic ring of styrene did not change its activity, whereas methylation of the side chain drastically reduced its effect on dopamine. Treatments carried out with the main metabolites of aromatic solvents indicated that acidic metabolites of some solvents cause striatal and tubero infundibular dopamine depletion. Present data suggested a chemical reaction between dopamine and some acidic metabolites. The active metabolites have an alpha-keto acid as the side chain or as a part of their molecule. These keto acids condense nonenzymatically with dopamine in both experimental models and in occupational exposed workers as evidenced by the direct measurements of dopamine in the brain. According to the authors, such a mechanism may account for neurobehavioral effects resulting from solvent exposure such as mood changes, or impaired attention spans and decreasing psychomotor performance factors.

Traces of ethylbenzene have been detected in exhaled air. It also occurs in the gas phase of smoke condensate and has been detected at 3.1 to 4.5 ppb in urban air.
[Clayton, G.D., F.E. Clayton (eds.) Patty's Industrial Hygiene and Toxicology. Volumes 2A, 2B, 2C, 2D, 2E, 2F: Toxicology. 4th ed. New York, NY: John Wiley & Sons Inc., 1993-1994. 1342]**PEER REVIEWED**

THREE LAB TECHNICIANS EXPOSED TO 42 PPM & 1 TO 34 PPM HAD AVG STEADY STATE BLOOD LEVELS OF 0.72 + OR - 0.11 MG/L. 30 MIN AFTER EXPOSURE CONCN HAD DROPPED TO APPROX 0.5% OF ORIGINAL VALUES.
[HAGEMANN J ET AL, KREBSGEFAEHRDUNG ARBEITSPLATZ/ARBEITSMED KOLLOQ, BER JAHRESTAG DTSCH GES ARBEITSMED 19TH: 421 (1979)]**PEER REVIEWED**

After exposure to 112-156 mg/l (aq) the skin absorption rate in humans (n= 14) was 0.11 to 0.21 mg/sq m/hr.
[Dutkiewicz T, Tyras H; Br J Ind Med 24 (4): 330-2 (1967)]**PEER REVIEWED**

When administered sc to 40 rats (2.5 ml, 1:1 v/v), ethylbenzene was detected in the blood within 2 hours, and the levels of ethylbenzene (10-15 ppm in blood) were maintained for at least 16 hours.
[USEPA; Ambient Water Quality Criteria Doc: Ethylbenzene p.C-6 (1980) EPA 440/5-80-048]**PEER REVIEWED**

After exposure of rats to atmospheres of 50, 300, or 600 ppm ethylbenzene 6 hr/day, 5 days/wk, for maximum of 16 wk, the concn of ethylbenzene in perirenal fat and the urinary excretion of 1-phenylethanol, omega-hydroxyacetophenone, mandelic acid, phenylglyoxylic acid, hippuric acid, and phenaceturic acid were measured at the 2nd, 5th, and 9th weeks. Excretion of metabolites into urine increased in a dose-related manner, but less than linearly. The level of exposure, but not the duration of

exposure, markedly affected the pattern of the metabolites in the urine. The concn of ethylbenzene in perirenal fat was low at 50 ppm, high at 300 ppm and higher still at 600 ppm, but not in proportion to the increased dose.
[Engstroem K et al; Xenobiotica 15 (4): 281-6 (1985)]**PEER REVIEWED**

Percutaneous absorption of benzene, toluene, ethylbenzene, and aniline was investigated in male HRS/J hairless mice. Stainless steel skin depots containing 100 to 150 mg of solid sorbent were fixed to the backs of anesthetized mice and charged with about 5 ul of (14)C tagged test solution. Expired air samples were obtained until 4 hours after exposure, when mice were killed and samples for radioactivity were obtained from the skin depot, the skin under the depot, a wiping of the skin under the depot, the carcass, feces, urine, and cage washings. Physical constants were determined for each test compound, including octanol/water partition coefficient, solubility, vapor pressure, melting and boiling points, and absorption and evaporation rates. Solvent recovery exceeded 90% in all mice with highest recovery in the skin depot. Average administered doses were 3.94 mg benzene, of which 0.99% was absorbed; 3.89 mg toluene (2.31% absorbed), 4.10 mg ethylbenzene (3.61% absorbed), and 4.68 mg aniline (4.76% absorbed). Excretion rate in expired air was fastest during the first 15 minutes of exposure except in mice treated with toluene or ethylbenzene, which demonstrated maximal excretion rate during the second 15 minutes after exposure. A two compartment model was suggested by the initial rapid and subsequent gradual decay of expired breath excretion. Vapor pressure and boiling point were significantly correlated with the applied radioactive dose absorbed. Absorption rates were found to be 56, 49, 37, and 2.3 ug per square centimeter per minute for benzene, toluene, ethylbenzene, and aniline, respectively.

Mechanism of Action:

The effect of styrene, toluene, ethylbenzene, alpha-methylstyrene, and butylbenzene on oxidative phosphorylation was studied using rat liver mitochondrial preparations. Rat liver mitochondria were prepared from male white Wistar rats and assessed for respiration rate, oxygen uptake, glutamate oxidation, succinate oxidation, ATPase activity, and proton permeability in the presence and absence of the alkyl benzene derivatives. Inclusion of the alkyl benzene derivatives in the incubation medium produced an initial acceleration of oxygen consumption followed by an inhibition of glutamate oxidation, and the stimulatory effect paralleled the aliphatic chain length. Glutamate oxidation was also inhibited by styrene, ethylbenzene, and alpha-methylstyrene but not by butylbenzene or toluene in 2,4-dinitrophenol uncoupled mitochondria. Styrene and the aliphatic benzene derivative stimulated succinate oxidation in rat liver mitochondria without effect on 2,4-dinitrophenol stimulated succinate oxidation. Similar stimulatory effects on ATPase activity were observed with maximal stimulation occurring at the same relative concentrations producing maximal succinate oxidation. ATPase stimulation required magnesium, was oligomycin sensitive, and showed an inverse relation to the hydrophobicity of the compounds tested. The inclusion of styrene in the incubation medium markedly increased the rate of passive entry of protons into rat liver mitochondria in a manner comparable to 2,4-dinitrophenol. It was concluded that styrene and other monosubstituted benzene derivatives act as mitochondrial uncoupling agents.
[Mickiewicz W, Rzeczycki W; Biochem Pharmacol 37 (23): 4439-44 (1988)]**PEER REVIEWED**

Effect of monocyclic aromatic hydrocarbons, their metabolites, and their structure on brain dopamine was studied. Adult male New Zealand rabbits were exposed to 750 ppm toluene, styrene, ethylbenzene, vinyltoluene, 7-methylstyrene, xylenes, and fresh air. Six groups of eight rabbits received 4 mM/kg ip for 3 days of hippuric acid, mandelic acid, methylhippuric acid, phenylglyoxylic acid, or 7-methylmandelic acid. Animals were killed 12 hours after inhalation exposure or 24 hours after the last dose of acid. The hypothalamus, striatum, hippocampus, tuberoinfundibular area, and part of the brain cortex were treated with 0.2 molar perchloric acid, homogenized, desorbed on alumina, and centrifuged. Supernatant was filtered and used to measure homovanillic acid. Styrene induced a marked dopamine depletion and a significant increase in homovanillic acid concentration. Ethylbenzene and vinyltoluene produced a smaller, but statistically significant effect. Toluene, xylenes, and 7-methylstyrene were ineffective. Phenylglyoxylic acid caused a decrease in dopamine levels and a consistent rise in homovanillic acid in striatal and tuberoinfundibular regions. Mandelic acid elicited the same effect, but to a lesser degree. 7-Methylmandelic, methylhippuric, and hippuric acids evoked no response. Neither solvents nor their metabolites affected norepinephrine contents of brain areas in which this neurotransmitter reaches high concentrations. It was concluded that the results indicate that the changes in brain dopamine depend on metabolic interferences of some metabolites of aromatic solvents with dopamine catabolism. Only metabolites whose side chain may be transformed into a alpha-keto acid caused dopamine depletion.
[Romanelli A et al; J Appl Toxicol 6 (6): 431-5 (1986)]**PEER REVIEWED**

The effect of organic solvents on the CNS was discussed. The similarity of effects of different solvents is believed to be due to the formation of tetrahydroisoquinolines by nonenzymatic condensation of

dopamine with metabolites of organic solvents having a reactive carbonyl group. The suspected metabolites are phenylglyoxylic- acid that is formed by metabolism of ethylbenzene, styrene, vinyltoluene; trichloroacetaldehyde, which derives from trichloroethylene, tetrachloroethylene; and trichloroethane; glyoxylic acid that is synthesized from ethyleneglycol and ethyleneglycolmonomethyl ether; formaldehyde that is metabolized from methanol; and acetaldehyde that is transformed from ethanol. The tuberoinfundibular dopaminergic system may represent a target for metabolites dissolved in the blood stream. The suggested mechanism implies a selective vulnerability of pituitary functions. The impairment of tuberoinfundibular activity may explain most of the behavioral changes observed with styrene and perhaps with other similar solvents. It appears that the majority of pathways that are affected in the hypothalamic control of gonadotropins in primates are adrenergic and dopaminergic. Occupational exposure to neurotoxins may cause repeated reversible CNS effects which are difficult to distinguish from the chronic effects. In workers exposed to styrene a relationship between recent exposure and measurable effects on CNS has been observed and prolonged exposure has failed to induce tolerance. It was concluded that although no excessive risk for Alzheimer disease and presenile dementia has been found, there is no indication that exposure to solvents does not cause irreversible or slowly reversible cognitive or neuropsychological impairment.
[Mutti A, Franchini I; Br J Ind Med 44 (11): 721-3 (1987)]**PEER REVIEWED**

Efforts were made to clarify the molecular basis of styrene toxicity on the dopaminergic systems and to evaluate whether the same mechanism was common to other solvents. Groups of male New Zealand rabbits were exposed to 750 ppm toluene, xylene, styrene, ethylbenzene, vinyltoluene, 7-methyl-styrene, or fresh air (control group). A significant depletion in both striatal and tubero infundibular dopamine was caused styrene, ethylbenzene, and vinyltoluene. Methylation of the aromatic ring of styrene did not change its activity, whereas methylation of the side chain drastically reduced its effect on dopamine. Treatments carried out with the main metabolites of aromatic solvents indicated that acidic metabolites of some solvents cause striatal and tubero infundibular dopamine depletion. Present data suggested a chemical reaction between dopamine and some acidic metabolites. The active metabolites have an alpha-keto acid as the side chain or as a part of their molecule. These keto acids condense nonenzymatically with dopamine in both experimental models and in occupational exposed workers as evidenced by the direct measurements of dopamine in the brain. According to the authors, such a mechanism may account for neurobehavioral effects resulting from solvent exposure such as mood changes, or impaired attention spans and decreasing psychomotor performance factors.

Environmental Fate & Exposure:

Environmental Fate/Exposure Summary:

Ethylbenzene's production and use as an intermediate for the production of styrene, its presence in automotive and aviation fuels, and its presence in crude oil may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 9.6 mm Hg at 25 deg C indicates ethylbenzene will exist solely as a vapor in the ambient atmosphere. Vapor-phase ethylbenzene will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 55 hr. If released to soil, ethylbenzene is expected to have moderate mobility based upon an estimated Koc of 520. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 7.88X10-3 atm-cu m/mole. Ethylbenzene may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation in soil takes place via nitrate-reducing processes. If released into water, ethylbenzene may adsorb to suspended solids and sediment in water based upon the estimated Koc. Biodegradation in a gasoline contaminated aquifer ranged from 10-16 days under aerobic conditions. Ethylbenzene was degraded in 8 days in groundwater and 10 days in seawater as a component of gas oil. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1.1 and 99 hrs, respectively. Measured BCFs of 0.67 to 15 suggest the potential for bioconcentration in aquatic organisms is low. Hydrolysis is not expected to occur due to the lack of hydrolyzable functional groups. Occupational exposure to ethylbenzene may occur through inhalation at municipal waste composting facilities and via inhalation and dermal contact with this compound at workplaces where ethylbenzene is produced or used. The general population may be exposed to ethylbenzene via inhalation of ambient air, drinking and eating contaminated foods and water, and by handling gasoline. Ethylbenzene is likely to be detected in groundwater. (SRC)
PEER REVIEWED

Probable Routes of Human Exposure:

NIOSH (NOES Survey 1981-1983) has statistically estimated that 80,726 workers (21,785 of these are female) are potentially exposed to ethylbenzene in the US(1). Occupational exposure to ethylbenzene may occur via inhalation at municipal waste composting facilities where the air concn was found to be 78,000-178,000 ug/cu m(2),and through inhalation and dermal contact with this compound at worplaces where ethylbenzene is produced or used(SRC). The general population may be exposed to ethylbenzene via inhalation of ambient air, ingestion of foods and fish, and drinking contaminated water, and dermal contact with this compound and other products such as gasoline which contains ethylbenzene(SRC).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of ethylbenzene with photochemically-produced hydroxyl radicals is 7.1X10-12 cu cm/molecule-sec at 298 K(1) which corresponds to an atmospheric half-life of about 55 hr at an atmospheric concn of 5X10+5 hydroxyl radicals per cu cm. Ethylbenzene is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(2). Ethylbenzene photolysis occurs via photooxidation hydrogen abstraction from the alkyl group by photooxydatively formed hydroxyl radical which results in the formation of acetophenone, and eventually benzaldehyde with 2-butanedial, 4-oxo-2-hexenal, and 2-ethyl-2-butenedial being suggested as further end products(3).
[(1) Atkinson R; J Phys Chem Ref Data Monograph No. 2 p. 48 (1994) (2) Lyman WJ et al; Handbook of Chemical Property Estimation Methods. Washington, DC: Amer Chem Soc pp. 7-4, 7-5 (1990) (3) Forstner HJL et al; Environ Sci Technol 31: 1345-58 (1997)]**PEER REVIEWED**

Environmental Bioconcentration:

Experimental data on the bioconcentration of ethylbenzene include a log BCF of 1.9 in goldfish(2) and a log BCF of 0.67 for clams exposed to the water-soluble fraction of crude oil(1). Experimentally, a log BCF of 1.19 has also been reported(4) which corresponds to a BCF of 15. According to a classification scheme(3), these BCFs suggest the potential for bioconcentration in aquatic organisms is low.

Environmental Water Concentrations:

DRINKING WATER: In surveys of representative US municipal water supplies, ethylbenzene has been detected in most cases(1,2,4-8,10). Values for 3 New Orleans finished drinking waters ranged 1.6 to 2.3 ppb(6). Chicago Central Water Works on Lake Michigan measured 4 ppb(8). It has been found in the water supply for Evansville, IN on the Ohio River(7). 6 of 10 US cities were found to be positive(1,4). One US city had 1 of 4 samples pos with a 1 ppb avg, while another reported no positive samples(5). Tap water from bank infiltrated Rhine River water in the Netherlands measured 30 ppb in one study(3). Zurich, Switzerland tap water - detected not quantified(9). 1982 US groundwater supply survey, random samples of finished water supplies using groundwater as a source, 466 random samples, 0.6%, pos (0.5 ppb detection limit), 0.8 ppb median, 1.1 ppb max(10).

GROUNDWATER: A well in Ames, IA measured 15 ppb 50 yr after tar residues were buried at a nearby coal gas plant(5). Concns of 82-400 ppb were detected in two aquifers near the Hoe Creek underground coal gasification site in Wyoming, 15 mo after gasification was complete(2). In a US survey, 1970-76, it was detected but not quantified in well waters(1). In Jackson Township, NJ, drinking water wells measured 2000 ppb(4). Chalk aquifer in East Anglia, England - 210 m from petroleum storage - 0.15 ppb, 10 m distance - 1110 ppb, and 100-200 m - <250 ppb(3).

SURFACE WATER: Ethylbenzene has been detected but not quantified in a 1970-76 US survey(1,4). 14 heavily industrialized US river basins, 5 of 204 sites pos - 1-4 ppb; Chicago area and Illinois River Basin, 5 of 31 sites pos - 1-4 ppb(6). Two representative US cities, city A - 41% of 28 samples pos, 5.0 ppb avg, city B - 40% of 48 samples pos 3.2 ppb avg(2). Lower Tennessee River near Calvert City, KY reported 4.0 ppb(7). Lake Michigan, Chicago Sanitary and Ship Channel measured 1-2 ppb(3). River Glatt, Switzerland -detected, not quantified(5). USEPA STORET database, 1,101 data points, 10% pos, <5.0 ppb median(8).

SEAWATER: Ethylbenzene concns were found to be 30-50 ng/l in an estuary in Brazos, US; between <10-46.3 ng/l in UK; and 36.9 ng/l in Belgium(1). Ethylbenzene has been found in concns of 4.5-30 ng/l in Vineyard Sound; 0.4-4.5 ng/l in coastal and shelf sea water in the Gulf of Mexico; 5.5-22 ng/l in the coastal waters of Spain; 4.3-380 ng/l in Campeche Shelf; <10 ng/l in shelf and bay waters in UK; and 9.4-18.7 ng/l in Belgian Continental Shelf(1). Ethylbenzene mean concn of 21.94 ng/l was found in the South Northern sea up to 60 km offshore in the Scheldt Estuary(2). In the coastal waters off the western Gulf of Mexico at the mouth of the Brazos River, TX, ethylbenzene concns range between 0.004-0.5 ug/l(3). In the Gulf of Mexico in unpolluted areas ethylbenzene concn is 0.4 to 5 ppb(4,6), while an area of anthropogenic influence ranged from 5 to 15 ppb(6). Cape Cod, MA measured ethylbenzene at 22 ppb(5,7) with 11 ppb being avg(5). In the coastal waters of the Dutch Northern Sea, 108 samples ranged from not detected to 20 parts per trillion and averaged 4 parts per trillion(8).

Sediment/Soil Concentrations:

SOIL: Ethylbenzene concns found in three leachate samples taken from German hazardous waste sites where leachate samples A and B were both anaerobic and alkaline and leachate sample C was aerobic and slightly acidic, were 10, 3200, and 20,000 ug/l, respectively(1). SEDIMENTS: Sediments from the lower Tennessee River below Calvert City, KY measured 4.0 ppb for ethylbenzene(2). According to the USEPA STORET database, 350 data points were tested for ethylbenzene with 11% pos, 5.0 ppm median, dry weight(3).

Atmospheric Concentrations:

SOURCE DOMINATED: The ethylbenzene concn measured 0.5-2.6 ppb in the Allegheny Mt. Tunnel, with concns directly corresponding to the number of vehicles passing through the tunnel(1). Emissions testing from motor vehicle traffic in a Los Angeles roadway tunnel showed concns of 143 mg/l of ethylbenzene(2). The Maastunnel in the Netherlands measured an avg ethylbenzene concn of 6 ppb(3). Concn (ppb) a rural motorway in UK, May-Aug 1983, 184 samples, not detected-1.14, 0.17 avg(4); Aug 1982, not detected-0.70, 0.25 avg(5). Ethylbenzene ambient air concns at 2 landfill sites in Ireland were found to have a min and max of 0.03 and 5.9, median of 0.8 ug/cu m (site with no leachate collection), and 0.03 and 47.6, median of 5.3 ug/cu m (site with leachate collection), respectively(6). Houston, TX 21 individuals in urban sites reported a range of 2.5 to 154.2 ppb(8). A natural gas facility in Rio Blanco County, CO measured 3.6 ppb, and a Texaco refinery in Tulsa, OK ranged from 4.7 to 7.9 ppb(7).

England - car park - 115 ppb, motorway - 92 ppb(9), while 6 sites at Gatwick airport ranged from 0.46 to 1.8 ppb, 1.4 ppb avg(10). 181 samples of US source dominated areas - 0.63 ppb avg(11).

Environmental Fate/Exposure Summary:

Ethylbenzene's production and use as an intermediate for the production of styrene, its presence in automotive and aviation fuels, and its presence in crude oil may result in its release to the environment through various waste streams. If released to air, a vapor pressure of 9.6 mm Hg at 25 deg C indicates ethylbenzene will exist solely as a vapor in the ambient atmosphere. Vapor-phase ethylbenzene will be degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals; the half-life for this reaction in air is estimated to be 55 hr. If released to soil, ethylbenzene is expected to have moderate mobility based upon an estimated Koc of 520. Volatilization from moist soil surfaces is expected to be an important fate process based upon a Henry's Law constant of 7.88X10-3 atm-cu m/mole. Ethylbenzene may volatilize from dry soil surfaces based upon its vapor pressure. Biodegradation in soil takes place via nitrate-reducing processes. If released into water, ethylbenzene may adsorb to suspended solids and sediment in water based upon the estimated Koc. Biodegradation in a gasoline contaminated aquifer ranged from 10-16 days under aerobic conditions. Ethylbenzene was degraded in 8 days in groundwater and 10 days in seawater as a component of gas oil. Volatilization from water surfaces is expected to be an important fate process based upon this compound's Henry's Law constant. Estimated volatilization half-lives for a model river and model lake are 1.1 and 99 hrs, respectively. Measured BCFs of 0.67 to 15 suggest the potential for bioconcentration in aquatic organisms is low. Hydrolysis is not expected to occur due to the lack of hydrolyzable functional groups. Occupational exposure to ethylbenzene may occur through inhalation at municipal waste composting facilities and via inhalation and dermal contact with this compound at workplaces where ethylbenzene is produced or used. The general population may be exposed to ethylbenzene via inhalation of ambient air, drinking and eating contaminated foods and water, and by handling gasoline. Ethylbenzene is likely to be detected in groundwater. (SRC)

Environmental Fate:

TERRESTRIAL FATE: Based on a classification scheme(1), an estimated Koc value of 520(SRC), determined from a structure estimation method(2), indicates that ethylbenzene is expected to have moderate mobility in soil(SRC). Volatilization of ethylbenzene from moist soil surfaces is expected to be an important fate process(SRC) given a Henry's Law constant of 7.88X10-3 atm-cu m/mole(3). The potential for volatilization of ethylbenzene from dry soil surfaces may exist(SRC) based upon a vapor pressure of 9.6 mm Hg(4). Ethylbenzene was completely degraded in microcosms inoculated with the sediment material from a refinery pond or activated sludge from the refinery treatment facility under nitrate-reducing conditions(5). At Sleeping Bear Dunes National Lakeshore in Michigan, ethylbenzene was degraded at slow rates via anaerobic degradation under ambient subsurface conditions using ferric iron, sulfate and/or carbon dioxide as the terminal electron acceptors(6).

AQUATIC FATE: Based on a classification scheme(1), an estimated Koc value of 520(SRC), determined from an estimation method(2), indicates that ethylbenzene may adsorb to suspended solids and sediment(SRC). Volatilization from water surfaces is expected(3) based upon a Henry's Law constant of 7.88X10-3 atm-cu m/mole(4). Using this Henry's Law constant and an estimation method(3), volatilization half-lives for a model river and model lake are 1.1 and 99 hr, respectively(SRC). According to a classification scheme(5), an experimental log BCF of 1.19(7), which corresponds to a BCF of 15, suggests the potential for bioconcentration in aquatic organisms is low. In a shallow coastal plain aquifer contaminated with gasoline and diesel fuel in rural Sampson County in North Carolina, ethylbenzene was degraded in aerobic conditions within 10-16 days and in conditions of low initial oxygen, it was rapidly degraded in 21 days until the available oxygen was depleted(8). As a component of gas oil, ethylbenzene is completely degraded in groundwater in 8 days(9) and seawater in 10 days(10). In a mesocosm experiment using simulated Narragansett Bay conditions, complete biodegradation occurred in approximately 2 days after a 2 week lag in spring and a 2 day lag in summer(11).

ATMOSPHERIC FATE: According to a model of gas/particle partitioning of semivolatile organic compounds in the atmosphere(1), ethylbenzene, which has a vapor pressure of 9.6 mm Hg at 25 deg C(2), is expected to exist solely as a vapor. Vapor-phase ethylbenzene is degraded in the atmosphere by reaction with photochemically-produced hydroxyl radicals(SRC); the half-life for this reaction in air is 55 hr(SRC), calculated from its rate constant of 7.1X10-12 cu cm/molecule-sec at 25 deg C(3).

Environmental Biodegradation:

After a period of inocula adaptation, ethylbenzene is biodegraded fairly rapidly by sewage or activated sludge inoculua(1-3,9). As a component of gas oil, it is completely degraded in groundwater in 8 days(4) and seawater in 10 days(5). In a mesocosm experiment using simulated Narragansett Bay conditions, complete biodegradation occurred in approximately 2 days after a 2 week lag in spring and a 2 day lag in summer(6). Part of the attenuation in concn from a leaky gasoline storage tank in the chalk aquifer in England has been attributed to biodegradation(7). No degradation was observed in an anaerobic reactor even after 110 days acclimation(8) or at low concentrations in a batch reactor in 11 weeks under denitrifying conditions(10). Percent removal in an anaerobic, continuous-flow, laboratory bioflim column was 7% after a 2 day detention time(11); 99% removal was observed in a similar aerobic column following a 20 min detention time(11).

AEROBIC: A study was conducted using underground storage tanks containing gasoline and diesel fuel that contaminated a shallow coastal plain aquifer in rural Sampson County in North Carolina. Ethylbenzene was degraded in aerobic conditions within 10-16 days and in conditions of low initial oxygen, it was rapidly degraded in 21 days until the available oxygen was depleted(1). A combined culture experiment of Mycobacterium vaccae and Rhodococcus sp. strain R-22 showed M. vaccae alone and M. vaccae and R-22 together can oxidize ethylbenzene to 4-ethylphenol which is then degraded to 50 ppm within 72 hr(2).

ANAEROBIC: Anaerobic ethylbenzene transformation in Seal Beach Naval Weapons Station sediments in Southern California appeared to be strictly associated with nitrate-reducing processes(1). Ethylbenzene was completely degraded in microcosms inoculated with the sediment material from a refinery pond or activated sludge from the refinery treatment facility under nitrate-reducing conditions(2). At Sleeping Bear Dunes National Lakeshore in Michigan, ethylbenzene was degraded at slow rates via anaerobic degradation under ambient subsurface conditions using ferric iron, sulfate and/or carbon dioxide as the terminal electron acceptors(3).

Environmental Abiotic Degradation:

The rate constant for the vapor-phase reaction of ethylbenzene with photochemically-produced hydroxyl radicals is 7.1X10-12 cu cm/molecule-sec at 298 K(1) which corresponds to an atmospheric half-life of about 55 hr at an atmospheric concn of 5X10+5 hydroxyl radicals per cu cm. Ethylbenzene is not expected to undergo hydrolysis in the environment due to the lack of hydrolyzable functional groups(2). Ethylbenzene photolysis occurs via photooxidation hydrogen abstraction from the alkyl group by photooxydatively formed hydroxyl radical which results in the formation of acetophenone, and eventually benzaldehyde with 2-butanedial, 4-oxo-2-hexenal, and 2-ethyl-2-butenedial being suggested as further end products(3).

Volatilization from Water/Soil:

The Henry's Law constant for ethylbenzene is 7.88X10-3 atm-cu m/mole(1). This Henry's Law constant indicates that ethylbenzene will volatilize from water surfaces(2). Based on this Henry's Law constant, the volatilization half-life from a model river (1 m deep, flowing 1 m/sec, wind velocity of 3 m/sec)(2) is estimated as 1.1 hr(SRC). The volatilization half-life from a model lake (1 m deep, flowing 0.05 m/sec, wind velocity of 0.5 m/sec)(2) is estimated as 99 hr(SRC). Ethylbenzene's Henry's Law constant(1) indicates that volatilization from moist soil surfaces may occur(SRC). The potential for volatilization of ethylbenzene from dry soil surfaces may exist(SRC) based upon a vapor pressure of 9.6 mm Hg(3). Environmental Water Concentrations:

DRINKING WATER: In surveys of representative US municipal water supplies, ethylbenzene has been detected in most cases(1,2,4-8,10). Values for 3 New Orleans finished drinking waters ranged 1.6 to 2.3 ppb(6). Chicago Central Water Works on Lake Michigan measured 4 ppb(8). It has been found in the water supply for Evansville, IN on the Ohio River(7). 6 of 10 US cities were found to be positive(1,4). One US city had 1 of 4 samples pos with a 1 ppb avg, while another reported no positive samples(5). Tap water from bank infiltrated Rhine River water in the Netherlands measured 30 ppb in one study(3). Zurich, Switzerland tap water - detected not quantified(9). 1982 US groundwater supply survey, random samples of finished water supplies using groundwater as a source, 466 random samples, 0.6%, pos (0.5 ppb detection limit), 0.8 ppb median, 1.1 ppb max(10).

SEAWATER: Ethylbenzene concns were found to be 30-50 ng/l in an estuary in Brazos, US; between <10-46.3 ng/l in UK; and 36.9 ng/l in Belgium(1). Ethylbenzene has been found in concns of 4.5-30 ng/l in Vineyard Sound; 0.4-4.5 ng/l in coastal and shelf sea water in the Gulf of Mexico; 5.5-22 ng/l in the coastal waters of Spain; 4.3-380 ng/l in Campeche Shelf; <10 ng/l in shelf and bay waters in UK; and 9.4-18.7 ng/l in Belgian Continental Shelf(1). Ethylbenzene mean concn of 21.94 ng/l was found in the South Northern sea up to 60 km offshore in the Scheldt Estuary(2). In the coastal waters off the western Gulf of Mexico at the mouth of the Brazos River, TX, ethylbenzene concns range between 0.004-0.5 ug/l(3). In the Gulf of Mexico in unpolluted areas ethylbenzene concn is 0.4 to 5 ppb(4,6), while an area of anthropogenic influence ranged from 5 to 15 ppb(6). Cape Cod, MA measured ethylbenzene at 22 ppb(5,7) with 11 ppb being avg(5). In the coastal waters of the Dutch Northern Sea, 108 samples ranged from not detected to 20 parts per trillion and averaged 4 parts per trillion(8).

Chemical Safety & Handling:

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Number. ... Isolate spill or leak area immediately for at least 50 to lOO meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs

Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, isolate for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Do not use dry chemical extinguishers to control fires involving nitromethane or nitroethane. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation,

ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. Preventive Measures:

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 132]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye

protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.
PEER REVIEWED

Employees should wash promptly when skin is wet or contaminated. Remove clothing immediately if wet or contaminated to avoid flammability hazard.

DOT Emergency Guidelines:

Fire or explosion: Highly flammable: Will be easily ignited by heat, sparks or flames. Vapors may form explosive mixtures with air. Vapors may travel to source of ignition and flash back. Most vapors are heavier than air. They will spread along ground and collect in low confined areas (sewers, basements, tanks). Vapor explosion hazard indoors, outdoors or in sewers. Some may polymerize (P) explosively when heated or involved in a fire. Runoff to sewer may create fire or explosion hazard. Containers may explode when heated. Many liquids are lighter than water.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Health: May cause toxic effects if inhaled or absorbed through skin. Inhalation or contact with material may irritate or burn skin and eyes. Fire will produce irritating, corrosive and/or toxic gases. Vapors may cause dizziness or suffocation. Runoff from fire control or dilution water may cause pollution.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Public safety: Call Emergency Response Telephone Number. ... Isolate spill or leak area immediately for at least 50 to lOO meters (160 to 330 feet) in all directions. Keep unauthorized personnel away. Stay upwind. Keep out of low areas. Ventilate closed spaces before entering.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Protective clothing: Wear positive pressure self-contained breathing apparatus (SCBA). Structural firefighters' protective clothing will only provide limited protection.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Evacuation: Large spill: Consider initial downwind evacuation for at least 300 meters (1000 feet). Fire: If tank, rail car or tank truck is involved in a fire, isolate for 800 meters (1/2 mile) in all directions; also, consider initial evacuation for 800 meters (1/2 mile) in all directions.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Fire: Caution: All these products have a very low flash point: Use of water spray when fighting fire may be inefficient. Small fires: Dry chemical, CO2, water spray or alcohol-resistant foam. Do not use dry chemical extinguishers to control fires involving nitromethane or nitroethane. Large fires: Water spray, fog or alcohol-resistant foam. Do not use straight streams. Move containers from fire area if you can do it without risk. Fire involving tanks or car/trailer loads: Fight fire from maximum distance or use unmanned hose holders or monitor nozzles. Cool containers with flooding quantities of water until well after fire is out. Withdraw immediately in case of rising sound from venting safety devices or discoloration of tank. Always stay away from the ends of tanks. For massive fire, use unmanned hose holders or monitor nozzles; if this is impossible, withdraw from area and let fire burn.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

Spill or leak: Eliminate all ignition sources (no smoking, flares, sparks or flames in immediate area). All equipment used when handling the product must be grounded. Do not touch or walk through spilled material. Stop leak if you can do it without risk. Prevent entry into waterways, sewers, basements or confined areas. A vapor suppressing foam may be used to reduce vapors. Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills: Dike far ahead of liquid spill for later disposal. Water spray may reduce vapor; but may not prevent ignition in closed spaces.
[U.S. Department of Transportation. 1996 North American Emergency Response Guidebook. A Guidebook for First Responders During the Initial Phase of aHazardous Materials/Dangerous Goods Incident. U.S. Department of Transportation (U.S. DOT) Research and Special Programs Administration, Office of HazardousMaterials Initiatives and Training (DHM-50), Washington, D.C. (1996).,p. G-129]**PEER REVIEWED**

First aid: Move victim to fresh air. Call emergency medical care. Apply artificial respiration if victim is not breathing. Administer oxygen if breathing is difficult. Remove and isolate contaminated clothing and shoes. In case of contact with substance, immediately flush skin or eyes with running water for at least 20 minutes. Wash skin with soap and water. Keep victim warm and quiet. Effects of exposure (inhalation, ingestion or skin contact) to substance may be delayed. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

Preventive Measures:

Contact lenses should not be worn when working with this chemical.
[NIOSH. NIOSH Pocket Guide to Chemical Hazards. DHHS (NIOSH) Publication No. 97-140. Washington, D.C. U.S. Government Printing Office, 1997. 132]**PEER REVIEWED**

SRP: The scientific literature for the use of contact lenses in industry is conflicting. The benefit or detrimental effects of wearing contact lenses depend not only upon the substance, but also on factors including the form of the substance, characteristics and duration of the exposure, the uses of other eye protection equipment, and the hygiene of the lenses. However, there may be individual substances whose irritating or corrosive properties are such that the wearing of contact lenses would be harmful to the eye. In those specific cases, contact lenses should not be worn. In any event, the usual eye protection equipment should be worn even when contact lenses are in place.

Laboratory Methods:

Clinical Laboratory Methods:

IN BLOOD BY ULTRAVIOLET-SPECTROPHOTOMETRIC METHOD.
[Browning, E. Toxicity and Metabolism of Industrial Solvents. New York: American Elsevier, 1965. 91]**PEER REVIEWED**

An automated high performance liquid chromatographic method for the direct determination of urinary concentrations of phenyl glyoxylic acid and mandelic acid, metabolites of styrene or ethylbenzene, is described. The method is simple and specific. Urine can be analyzed without solvent extraction. Analysis can be performed satisfactorily within 15 minutes for samples containing hippuric acid, o-, m- and p-methyl hippuric acids, phenyl glyoxylic acid, and mandelic acid, and within 15 minutes for those containing hippuric acid, phenyl glyoxylic acid and mandelic acid.
[Ogata M, Taguchi T; Int Arch Occup Environ Health 59 (3): 263-72 (1987)]**PEER REVIEWED**

Analytic Laboratory Methods:

EPA Method 624. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the analysis of purgeable organics including ethylbenzene in the municipal and industrial discharges. Under the prescribed conditions, for ethylbenzene the method has a detection limit of 7.2 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 1624. Isotope Dilution Purge-and-Trap Gas Chromatography/Mass Spectrometry. This method is applicable for the determination of volatile organic compounds in municpal and industrial discharges. By adding a known amount of a labeled compound to every sample prior to purging, a correction of recovery of the pollutant can be made. If labeled compounds are not available, an internal standard method is used. Under the prescribed conditions, for both the labeled, and unlabeled ethylbenzene the method has a minimum detection level 10 ug/l.The established acceptance performance criteria at 20 ug/l is 9.6 ug/l for the standard deviation of the recovery, with the average recovery of 15.6 to 28.5 ug/l and the labeled cmpd recovery ranging from below detection to 203%.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 602. Purge-and-Trap Gas Chromatography with photoionization detection for the determination of purgeable aromatics including ethylbenzene in municipal and industrial discharges. Under the prescribed conditionss for ethylbenzene the detection limit is 0.2 ug/l. The method is applicable for use in the concentration range from the method detection limit to times that limit. Precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 524.2. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the determination of volatile aromatic compounds in water including finished drinking water, raw source water, and drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.06 ug/l and a relative standard deviation of 8.6% with a wide bore capillary column, and a method detection limit of 0.03 ug/l and a relative standard deviation of 5.3% with a narrow bore capillary column.
[USEPA; Methods for the Determinatioon of Organic Compounds in Finished Drinking Water and Raw Source Water (19860]**PEER REVIEWED**

EPA Method 503.1. Purge-and-Trap Gas Chromatography with a Photoionization Detector. The method is applicable for the determination of volatile aromatic and unsaturated organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.002 ug/l and a relative standard deviation of 8.5%. Overall precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of sample matrix.
[USEPA; Methods for the Determination of Organic Compouds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 502.2: Purge-and-Trap Capillary Column Gas Chromatography with Photoionization and Electrolytic Conductivity Detectors in Series. The method is applicable for the determination of volatile organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.005 ug/l, a percent recovery of 101%, and a standard deviation of 1.4 using the photoionization detector; and there is no data given for the following: the method detection limit, a percent recovery, or the standard deviation of recovery using the electrolytic conductivity detector.
[USEPA; Methods for the Determination of Organic Compounds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

NIOSH Method 1501. Determination of Aromatic Hydrocarbons by Gas Chromatography with Flame Ionization Detection.
[U.S. Department of Health and Human Services, Public Health Service, Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSH Manual of Analytical Methods. 4th ed.Methods A-Z & Supplements. Washington, DC: U.S. Government Printing Office, Aug 1994.]**PEER REVIEWED**

EPA Method 8240. Gas Chromatography/Mass Spectrometry for the determination of volatile organics. This method can be used to quantify most volatile organic compounds including ethylbenzene that have boiling points below 200 deg C and are insoluble or slightly soluble in water. The detection limit is not given. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[USEPA/Office of Solid Waste (OSW); Test Methods for Evaluating Solid Waste, Physical/Chemical Methods SW846 Methods (1986)]**PEER REVIEWED**

EPA Method 8260. Gas Chromatography/Mass Spectrometry for the determination of volatile organic compounds. This method can be used to quantitate most volatile organic compounds including ethylbenzene that have boiling points below 200 deg C and are insoluble or slightly soluble in water.

Under the prescribed conditions for ethylbenzene, the method has a detection limit of 0.06 ug/l, a percent recovery of 99%, and a percent relative standard deviation of 8.6% using a wide bore capillary column; and a detection limit of 0.03 ug/l, a percent recovery of 99%, and a percent relative standard deviation of 5.3% using a narrow bore capillary column.

IN BLOOD BY ULTRAVIOLET-SPECTROPHOTOMETRIC METHOD.
[Browning, E. Toxicity and Metabolism of Industrial Solvents. New York: American Elsevier, 1965. 91]**PEER REVIEWED**

An automated high performance liquid chromatographic method for the direct determination of urinary concentrations of phenyl glyoxylic acid and mandelic acid, metabolites of styrene or ethylbenzene, is described. The method is simple and specific. Urine can be analyzed without solvent extraction. Analysis can be performed satisfactorily within 15 minutes for samples containing hippuric acid, o-, m- and p-methyl hippuric acids, phenyl glyoxylic acid, and mandelic acid, and within 15 minutes for those containing hippuric acid, phenyl glyoxylic acid and mandelic acid.

Analytic Laboratory Methods:

EPA Method 624. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the analysis of purgeable organics including ethylbenzene in the municipal and industrial discharges. Under the prescribed conditions, for ethylbenzene the method has a detection limit of 7.2 ug/l. Precision and method accuracy were found to be directly related to the concentration of the analyte and essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 1624. Isotope Dilution Purge-and-Trap Gas Chromatography/Mass Spectrometry. This method is applicable for the determination of volatile organic compounds in municpal and industrial discharges. By adding a known amount of a labeled compound to every sample prior to purging, a correction of recovery of the pollutant can be made. If labeled compounds are not available, an internal standard method is used. Under the prescribed conditions, for both the labeled, and unlabeled ethylbenzene the method has a minimum detection level 10 ug/l.The established acceptance performance criteria at 20 ug/l is 9.6 ug/l for the standard deviation of the recovery, with the average recovery of 15.6 to 28.5 ug/l and the labeled cmpd recovery ranging from below detection to 203%.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 602. Purge-and-Trap Gas Chromatography with photoionization detection for the determination of purgeable aromatics including ethylbenzene in municipal and industrial discharges. Under the prescribed conditionss for ethylbenzene the detection limit is 0.2 ug/l. The method is applicable for use in the concentration range from the method detection limit to times that limit. Precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of the sample matrix.
[40 CFR 136 (7/1/91)]**PEER REVIEWED**

EPA Method 524.2. Purge-and-Trap Gas Chromatography/Mass Spectrometry for the determination of volatile aromatic compounds in water including finished drinking water, raw source water, and drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.06 ug/l and a relative standard deviation of 8.6% with a wide bore capillary column, and a method detection limit of 0.03 ug/l and a relative standard deviation of 5.3% with a narrow bore capillary column.
[USEPA; Methods for the Determinatioon of Organic Compounds in Finished Drinking Water and Raw Source Water (19860]**PEER REVIEWED**

EPA Method 503.1. Purge-and-Trap Gas Chromatography with a Photoionization Detector. The method is applicable for the determination of volatile aromatic and unsaturated organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.002 ug/l and a relative standard deviation of 8.5%. Overall precision and method accuracy were found to be directly related to the concentration of the analyte essentially independent of sample matrix.
[USEPA; Methods for the Determination of Organic Compouds in Finished Drinking Water and Raw Source Water (1986)]**PEER REVIEWED**

EPA Method 502.2: Purge-and-Trap Capillary Column Gas Chromatography with Photoionization and Electrolytic Conductivity Detectors in Series. The method is applicable for the determination of volatile organic compounds in finished drinking water, raw source water, or drinking water in any treatment stage. For ethylbenzene the method has a detection limit of 0.005 ug/l, a percent recovery of 101%, and a standard deviation of 1.4 using the photoionization detector; and there is no data given for the following: the method detection limit, a percent recovery, or the standard deviation of recovery using the electrolytic conductivity detector.

DOE Method OS040. Rapid Determination Of Volatile Organic Contaminants in Water and Soils by Direct Purge Mass Spectrometry.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

DOE Method OS060. Immunoassay for Petroleum Fuel Hydrocarbons in Soil.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EAD Method 1624. Volatile Organic Compounds by Isotope Dilution GCMS.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EAD Method 1624. Volatile Organic Compounds by Isotope Dilution GCMS.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 502.2. Volatile Organic Compounds in Water by Purge and Trap Capillary Column Gas Chromatography with Photoionization and Electrolytic Conductivity Detectors in Series.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 503.1. Volatile Aromatic and Unsaturated Organic Compounds in Water by Purge and Trap Gas Chromatography.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 524.1. Measurement of Purgeable Organic Compounds in Water by Packed Column Gas Chromatography and Mass Spectrometry.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 524.2 Measurement of Purgeable Organic Compounds in Water by Capillary Column

Gas Chromatography/Mass Spectrometry.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 602. Purgeable Aromatics in Wastewater by Gas Chromatography with Photoionization Detection.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 624. Protocol for the Analysis of Purgeable Organic Priority Pollutants in Industrial and Municipal Wastewater.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

EMSLC Method 624-S. Analysis of Purgeable Organic Priority Pollutants in Industrial and Municipal Wastewater Treatment Sludge.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

SFSAS Method SFSAS_7. Determination of Purgeable Organics in Sediment.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

AOB Method VS-006-1. Volatile Organic Compounds (VOCs) in Soil and Water by Purge and Trap GC.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

AOB Method VW-011-1. Field Screening for Volatile Organic Compounds (VOCs) in Water and Soil by Purge and Trap GC/PID/ELCD.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

CLP Method OHC. Organics Analysis, Multi-Media, High-Concentration.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

SFSAS Method SFSAS_29. Extraction and Analysis of Organics in Biological Tissue.
[USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

SFSAS Method SFSAS_5. Analysis of Fish for Volatile Organics by Purge and Trap Analysis. [USEPA; EMMI. EPA's Environmental Monitoring Methods Index. Version 1.1. PC#4082. Rockville, MD: Government Institutes (1997)]**PEER REVIEWED**

ETHYLBENZENE

CASRN: 100-41-4

Sampling Procedures:

AIR SAMPLES WERE COLLECTED IN TEFLON LOOP (3.0 ML).
[IMAMURA K ET AL; BUNSEKI KAGAKU 28 (9): 549 (1979)]**PEER REVIEWED**

NIOSH Method 1501. Analyte: Ethylbenzene. Matrix: Air. Sampler: Solid sorbent tube (coconut shell charcoal, 100 mg/50 mg). Flow Rate: less or equal to 0.2 l/min. Sample Size: 10-24 liters. Shipment: no special specifications. Sample Stability: not determined.
[U.S. Department of Health and Human Services, Public Health Service. Centers for Disease Control, National Institute for Occupational Safety and Health. NIOSHManual of Analytical Methods, 3rd ed. Volumes 1 and 2 with 1985 supplement, and revisions. Washington, DC: U.S. Government Printing Office, February 1984.,p. 1501-1]**PEER REVIEWED**
